I understand that the following information in the FCI application will be made available on the LCFS ~~web site~~website: Name of the Applicant Entity, Site Name, Site Address, Number and Type of Charging Units, Nameplate and Effective Simultaneous Power Rating for Each Unit, and Effective Date Range for FCI Crediting

By submitting this application, ____(applicant entity) accepts responsibility for the information herein provided to CARB. I certify under penalty of perjury under the laws of the State of California that I have personally examined, and am familiar with, the statements and information submitted in this document. I certify that the statements and information submitted to CARB are true, accurate, and complete.

(K) CBI must be designated pursuant to the requirements described in section 95488.8(c).

(L) An application and supporting documents must be submitted electronically via the LRT-CBTS unless the Executive Officer has approved or requested in writing another format.

(3) *Application Approval Process.*

(A) The FCI application must be approved by the Executive Officer before the applicant may generate FCI credits. If estimated potential FCI credits from all approved FSEs exceed 2.5 percent of deficits in the prior quarter, the Executive Officer will not approve additional FCI pathways and will not accept additional applications until FCI credits are less than 2.5 percent of deficits. FCI applications will be evaluated for approval on a first come, first served basis.

Estimated potential FCI credits will be calculated using the following equation:

$$Credits_{FCI}^{Potential} = Credits_{FCI}^{Prior\ qtr} \times \frac{Cap_{FCI}^{Approved}}{Cap_{FCI}^{Operational}}$$

where:

$Credits_{FCI}^{Potential}$ means the estimated potential FCI credits from all approved FSEs;

$Credits_{FCI}^{Prior\ qtr}$ means the total FCI credits generated by operational FSEs in the prior quarter;

$Cap_{FCI}^{Operational}$ means the total FCI charging capacity of FSEs that were operational in the prior quarter; and

$Cap_{FCI}^{Approved}$ means the total FCI charging capacity of all approved FSEs, both operational and nonoperational.

(B) The estimated potential FCI credits for an individual applicant will be calculated using the same equation as in subsection (A) above, where:

$Credits_{FCI}^{Potential}$ means the estimated potential FCI credits from the applicant's approved FSEs;

$Credits_{FCI}^{Prior\ qtr}$ means the total FCI credits generated by the applicant for operational FSEs in the prior quarter;

$Cap_{FCI}^{Operational}$ means the total FCI charging capacity of the applicant's FSEs that were operational in the prior quarter; and

$Cap_{FCI}^{Approved}$ means the total FCI charging capacity of all of the applicant's approved FSEs, both operational and nonoperational.

(C) After receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer shall advise the applicant in writing either that:

1. The application is complete, or

2. The application is incomplete, in which case the Executive Officer will identify which requirements of section 95486.2(b)(2) have not been met.

   a. The applicant may submit additional information to correct deficiencies identified by the Executive Officer.

   b. If the applicant is unable to achieve a complete application ~~within 180 days~~during the quarter of the Executive Officer's receipt of the original application, the application will be denied on that basis, and the applicant will be informed in writing. The applicant may submit a new application for the station.

3. At any point during the application evaluation process, the Executive Officer may request in writing additional information or clarification from the applicant.

(D) The Executive Officer shall not approve an application if the Executive Officer determines, based upon the information submitted in the application and any other available information, that the application does not meet requirements in subsections 95486.2(b)(1) and (b)(2). If the Executive Officer does not approve the application, the applicant will be notified in writing and the basis for the disapproval shall be identified.

(E) If the Executive Officer determines the application has met all requirements for approval pursuant to subsections 95486.2(b)(1) and (b)(2), the Executive Officer will approve the application and provide an approval summary on the LCFS website including the site location and FSE ID, number and type of FSE, nameplate and effective simultaneous power rating for each FSE, and effective date range for FCI pathway crediting.

(F) *Crediting Period.* FCI crediting is limited to 5 years starting with the quarter following Executive Officer approval of the application.

(4) *Requirements to Generate FCI Credits.* To generate credits using FCI pathways the following conditions must be met. The applicant must maintain, and submit to CARB upon request, records demonstrating adherence to these conditions.

(A) The applicant must update the nameplate and effective simultaneous power rating of FSE if different from the power rating provided in the application. Any FSE design or operational information that deviates from the original application must be declared to the Executive Officer, and a new attestation must be submitted using the language in section 95486.2(b)(2).

(B) The FSE must be open to the public, meaning that no obstructions or obstacles exist to preclude vehicle operators from entering the FSE premises, no access cards or personal identification (PIN) codes are required for the FSE to dispense fuel, and no formal or registered equipment training shall be required for individuals to use the FSE.

(C) The FSE that charges a fee for service must be capable of supporting a public point-of-sale method that accepts all major credit or debit cards.

(D) The FSE passed final inspection by the appropriate authority having jurisdiction and has a permit to operate.

(E) The FSE owner has fully commissioned the FSE, and has declared it fit to service retail EV drivers.

(F) The FSE registration must be completed pursuant to section 95483.2(b)(8) and the quantity of dispensed electricity must be reported as required in section 95491.

(G) The FSE must be operational within 12 months of application approval. If the applicant fails to demonstrate the operability within 12 months of approval then the application will be canceled. The applicant can reapply for the same FSE site eligible only for 2 years of crediting.

(H) The estimated cumulative value of FCI credits generated for the FSE in the prior quarter must be less than the difference between the total capital expenditure reported pursuant to section 95486.2(b)(6)(B)1 and the total grant revenue or other funding reported pursuant to section 95486.2(b)(6)(B)5 in the prior quarter.

1. The estimated value of FCI credits, for the purpose of this determination, shall be calculated using the number of FCI credits generated for the FSE in the quarter and the average LCFS credit price for that quarter published on the LCFS website.

2. The cumulative credit value generated for each FSE will be tracked as the sum of all quarterly credit values in constant-dollar for the year in which the FCI application was approved using an annual discount rate of 10%.

3. The estimated value calculated under this provision will be made available only to the respective reporting entity in LRT-CBTS and will not be published on the LCFS website.

4. This will not affect the reporting entity's ability to generate non-FCI LCFS credits for the electricity dispensed at the FSE.

(5) *Calculation of FCI Credits.* FCI credits will be calculated using the following equation for each FSE approved under this provision:

$$Credits_{FCI}\ (MT) = (CI^{XD}_{standard} \times EER - CI_{FCI}) \times C_{Elec} \times \left(Cap^{i}_{FCI} \times N \times UT - Elec_{disp}\right) \times C$$

where:

$CI^{XD}_{standard}$ is the average carbon intensity requirement of gasoline (XD = "gasoline") for a given year as provided in section 95484(b);

EER is the dimensionless Energy Economy Ratio for Electricity/BEV or PHEV relative to gasoline as listed in Table 5;

CI_{FCI} is the California average grid electricity carbon intensity as listed in Table 7-1;

C_{Elec} is the conversion factor for electricity as listed in Table 4;

Cap^{i}_{FCI} is the FCI charging capacity (kWh/day) for the FSE;

N is the number of days during the quarter;

UT is the uptime multiplier which is the fraction of time that the FSE is available for charging during the quarter;

$Elec_{disp}$ is the quantity of electricity dispensed during the quarter (kWh);

C is a factor used to convert credits to units of metric tons from gCO_2e and has the value of:

$$C = 1.0x10^{-6} \frac{(MT)}{(gCO_2e)}$$

(6) *Reporting and Recordkeeping Requirements.* The following must be reported to the Executive Officer each quarter as set forth in section 95491 before credits will be issued to the LRT account associated with an approved FCI pathway.

(A) FSE availability. This is the percentage of hours the FSE is available for charging during the quarter relative to the permitted hours of operation for the site.

(B) Cost and revenue data. Provide a quarterly account of the following costs borne and revenues received by the FSE owner up through the most recent reporting quarter per site.

1. Total capital expenditures ($)

2. Total delivered cost ($) of electricity, including demand charges, and average delivered cost ($/kWh) for electricity

3. Total maintenance costs ($)

4. Total land rental cost ($)

5. Total grant revenue or other external funding received towards capital expenditures ($)

6. Total grant revenue or other external funding received towards operational and maintenance expenditures ($)

7. Total revenue ($) received from sale of electricity and average retail price ($/kWh) for electricity sold

8. Other operational expenditures ($)

(7) *~~Applications for Expanded~~ Transition to Light-Duty Fast Charging Infrastructure (LD-FCI ~~Capacity.~~* ~~Applicants who increase the~~*) Pathways.* Beginning January 1, 2026, an FSE owner or designee may submit an application to certify an LD-FCI pathway. The LD-FCI pathway retains the requirements of the FCI pathway, with the following amendments:

(A) Subsection 95486.2(b)(1)(A) is amended. The proposed LD-FCI station must be located in California in a low-income or disadvantaged community, or at least 10 miles from the nearest direct current fast charger open to the public with a nameplate capacity equal to or greater than 150 kW.

(B) Subsection 95486.2(b)(1)(C) is amended. The proposed LD-FCI pathway application must be received on or before December 31, 2030.

(C) Subsection 95486.2(b)(1)(E)1. is amended. The total nameplate power rating ~~of an~~for all FSE ~~or add an FSE to~~at a single site ~~that is already generating~~ claiming FCI credit under this provision cannot exceed 1,000 kW.

(D) Subsection 95486.2(b)(2)(D) is amended. The number of FSEs at an LD-FCI site cannot exceed 4.

(E) Subsection 95486.2(b)(2)(G) is amended. The FCI charging capacity for each FSE calculated using the following equation:

$$Cap^{i}_{MHD-FCI} = 0.2 \times P^{i}_{MHD-FCI} \times 24$$

where:

Cap^{i}_{FCI} is the FCI charging capacity (kWh/day) for the FSE i;

P^{i}_{FCI} is the nameplate power rating for the FSE or 350 kW, whichever is less; and

24 is the number of hours in a day (hr/day)

(F) Subsection 95486.2(b)(3)(A) is amended. If estimated potential LD-FCI credits ~~under the LCFS must submit an application to~~ from all approved stations exceed 0.5 percent of deficits in the most recent quarter data is available, the Executive Officer ~~to generate~~will not approve additional LD-FCI pathways and will not accept additional applications until estimated potential LD-FCI credits ~~based on the increased power or number of FSEs. Applications must be received before December 31, 2025 and do not extend the end date for the~~ are less than 0.5 percent of deficits. LD-FCI potential credits are calculated separately from FCI potential credits described in this section.

(G) Subsection 95486.2(b)(3)(F) is amended. LD-FCI crediting ~~specified upon~~is limited to 10 years starting with the quarter of Executive Officer approval of the application.

(H) Subsection 95486.2(b)(4)(G) is amended. If the applicant fails to demonstrate the operability within 12 months of approval and if the estimated potential LD-FCI credits exceed 0.5 percent of deficits in the most recent quarter deficit data is available, then the application will be canceled. The applicant can submit a new application for the same station the following quarter. The estimated value of LD-FCI credits, for the purpose of this determination, shall be calculated using the number of LD-FCI credits generated for the station in the quarter and the average LCFS credit price for that quarter published on the LCFS website.

(I) Subsection 95486.2(b)(4)(H) is amended. The estimated cumulative value of LD-FCI credits generated for the station in the prior quarter must be less than the difference between 1.5 times the initial ~~project approval in 95486.2(b)(3). The application must~~ capital expenditure, not including on-site generation, and the sum of total grant revenue or other external funding received towards capital, operational and maintenance expenditures in the prior quarter, reported pursuant to section 95486.2(b)(6)(B).

(J) Subsection 95486.2(b)(6)(B) is amended. Provide an annual account of the following costs borne and revenues received for the site. in the owner's annual report. The cost and revenue account must be included in the annual report submitted pursuant to section 95491.

~~(7)~~(K) Subsection 95486.2(b)(6)(B)1. is amended to include ~~the following elements~~a a breakdown of initial capital expenditure by equipment, labor, materials, fees and land ($). Costs for working capital and off-site facilities are not included.

~~(A) Updated number and type of FSE at the site.~~

~~(B) Updated FCI charging capacity, nameplate power rating and effective simultaneous power rating for each FSE at the site.~~

~~(C) The applicant must maintain records demonstrating that any new equipment added as a result of the expansion in capacity meet the requirements listed in 95486.2(b).~~

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95487. Credit Transactions.

(a) *General.* LCFS credits shall not constitute instruments, securities, or any other form of property.

(1) A regulated entity may:

(A) Retain LCFS credits without expiration for use within the LCFS market; and

(B) Acquire or transfer LCFS credits. A third-~~-~~ party, which is not a regulated entity or acting on behalf of a regulated entity, may not hold, purchase, sell, or trade LCFS credits, except as otherwise specified in section 95483.

(2) A regulated entity may not:

(A) Use credits in the LCFS program that are generated outside the LCFS program, including credits generated in other tradeable emission credit programs administered by the California Air Resources Board.

(B) Borrow or use credits from anticipated future carbon intensity reductions to demonstrate compliance pursuant to section 95485(a). This does not preclude contracting for future delivery of LCFS credits as described in section 95487(b)(1)(B), nor participation in the credit clearance market described in section 95485(c).

(C) Generate LCFS credits from fuels exempted from the LCFS under section 95482(d) or are otherwise not eligible pursuant to section 95482.

(D) Sell or transfer credits at a price that exceeds the Maximum Price set by the following formula:

1. \$200/credit ($MTCO_2e$) in 2016.

2. This per credit price shall be adjusted annually by the rate of inflation as measured by the most recently available twelve months of the Consumer Price Index for All Urban Consumers.

   “Consumer Price Index for All Urban Consumers” means a measure that examines the changes in the price of a basket of goods and services purchased by urban consumers, and is published by the U.S. Bureau of Labor Statistics.

3. The Maximum Price will be published on the first Monday of April and go into effect on June ~~1st~~1.

(b) *Credit Transfers between Parties.*

(1) A regulated entity that wishes to sell or transfer credits (“the Seller”) and a regulated entity that wishes to purchase or acquire a credit (“the Buyer”)

may enter into an agreement to transfer credits. Any such agreement must be fully documented in the LRT-CBTS pursuant to section 95487(b)(1)(B) through (F).

(A) *General Requirements for Credit Transfers.* The Seller may transfer credits provided the number of credits to be transferred by the Seller does not exceed the number of total credits in the Seller's credit account defined as follows:

$$Total\ Credits = Credits^{Gen} + Credits^{Aquired} - Sum\ of\,(Credits^{Retired} + Credits^{OnHold} + Credits^{Sold} + Credits^{Exported} + Credits^{CCMPledge})$$

where:

$Credits^{Gen}$, $Credits^{Aquired}$, $Credits^{Retired}$, $Credits^{OnHold}$, $Credits^{Sold}$, $Credits^{Exported}$, and $Credits^{CCMPledge}$ have the same meaning as those in section 95485(b).

(B) The credit transfer request must identify the type of transaction agreement for which the transfer request is being submitted, selecting one of the following types:

1. *Type 1 Transfer*: Over-the-counter agreement for the sale or transfer of LCFS credits for which delivery will take place no more than 10 days from the date the parties enter into the transaction agreement.

2. *Type 2 Transfer*: Over-the-counter agreement for the sale or transfer of LCFS credits for which delivery is to take place more than 10 days from the date the parties enter into the transaction agreement or that involve multiple transfers of LCFS credits over time.

3. *Type 3 Transfer*: Agreements for the sale of LCFS credits through any contract arranged through a clearing service provider.

(C) *For Type 1 Transfer.* Within 10 days from the date the parties enter into the credit transaction agreement, the Seller and the Buyer must initiate and complete the transfer request using the Credit Transfer Form (CTF) provided in the LRT-CBTS. The parties must provide:

1. *Date of Transaction Agreement.* The date on which the Buyer and Seller enter into the credit transaction agreement;

2. Names and the Federal Employer Identification Numbers (FEIN) of the Seller and the Buyer as registered in the LRT-CBTS;

3. First name, last name, and contact information of the Seller and Buyer representative;

4. The number of credits proposed to be transferred; and

5. The price or equivalent value of the consideration (in U.S. dollars) per credit proposed for transfer, excluding any fees.

(D) *For Type 2 Transfer.* Within 10 days from the date the parties enter into the credit transaction agreement, the Seller and the Buyer must report the following using the Credit Transfer Form (CTF) provided in the LRT-CBTS:

1. *Date of Transaction Agreement.* The date on which the Buyer and Seller enter into the credit transaction agreement;

2. Names and the Federal Employer Identification Numbers (FEIN) of the Seller and the Buyer as registered in the LRT-CBTS;

3. First name, last name, and contact information of the Seller and Buyer representative;

4. If the agreement requires a single delivery of credits or multiple deliveries of credits. The Executive Officer may assign reference numbers for reporting future credit transfers under agreements for multiple deliveries of credits;

5. The expected date of last credit delivery or the length of the agreement including the date by which all deliveries are to be completed;

6. The total number of credits anticipated to be transferred under the agreement;

7. The price per credit (in U.S. dollars) or the terms to determine the price for future credit transfer as per the agreement;

8. If the agreement is terminated or amended prior to its full execution as provided in subsection 5. above, the parties must notify the Executive Officer within 10 days; and

9. If the credit transfer is one of multiple deliveries under an agreement previously reported using a CTF, the parties must provide the reference number (if any) assigned by the Executive Officer.

(E) *For Type 3 Transfer.* A credit transfer request submitted for an agreement executed through a clearing service provider must provide the following information:

1. Identify the exchange through which the transaction is conducted;

2. Date of close of trading for the contract;

3. Identify the contract description code assigned by the exchange to the contract;

4. Price at close of trading for the contract;

5. The number of credits in the contract to be transferred; and

6. Date of delivery of LCFS credits covered by the contract.

(F) If the transaction agreement does not specify the price for LCFS credits, the Seller must provide a brief description of the pricing method for the full transaction inclusive of all products and value exchanged. The seller must also select one of the following options:

1. The proposed transfer is to reflect an adjustment in CI value of fuel transacted between Seller and Buyer;

2. The proposed transfer incorporates a credit trade along with the sale or purchase of other product, and does not specify a price or cost basis for the sale of the credits alone.

(G) *Recording a Credit Transfer.* Upon receiving a fully-completed CTF, the Executive Officer shall, either:

1. Process and approve the transfer request and update the account balances of the Seller and Buyer to reflect the credit transfer, provided the Executive Officer determines all required information was submitted, and it accurately reflects the parties' positions at the time of the proposed transfer; or

2. Notify the parties that the proposed credit transfer is infeasible and identify the reasons for rejecting the transfer.

(2) *Facilitation of Credit Transfer.* A Seller or Buyer may elect to use a third-party broker as defined in section 95481 to facilitate the transfer of credits. A broker cannot acquire credits. A broker who will document transfers in LRT-CBTS must register in the LRT CBTS, and the Buyer, Seller, or both must document, using the LRT CBTS, authorization for broker to act on their behalf. A broker may, with the consent of the parties, conduct a "blind transaction" where the Buyer of the credit does not know the identity of the Seller, and/or the Seller of the credit does not know the identity of the Buyer.

(3) *Correcting Credit Transfer Errors.* A regulated entity is responsible for the accuracy of information submitted to the Executive Officer. If a regulated entity discovers an error in the information reported to the Executive Officer or recorded by the Executive Officer, the regulated entity must inform the Executive Officer in writing within five (5) days of the discovery and request a correction. Each submitted request is subject to Executive Officer review and approval. If the Executive Officer determines that the error occurred during the recording of the credit by Board staff, the Executive Officer will make the correction and no additional re-submissions are required.

(c) *Public Disclosure of Credit and Deficit Balances and Credit Transfer Information*.

(1) The Executive Officer shall, no less frequently than quarterly, provide to the public reports containing a summary of credit generation and transfer information including, but not limited to:

(A) Total deficits and credits generated or incurred in the most recent quarter for which data are available, including information on the types and quantities of fuels used to generate credits.

(B) Total deficits and credits generated or incurred in all previous quarters of the most recent year for which data are available, including information on the types and quantities of fuels used to generate credits.

(C) Total credits in regulated entities' accounts and the total number of outstanding deficits carried over by regulated entities from a previous compliance year.

(D) Information on the credits transferred during the most recent quarter for which data is available including the total number of credits transferred, the number of transfers, the number of parties making transfers, and the monthly average credit price for transfers that reported a price.

(2) The Executive Officer shall provide reports, no less frequently than monthly, to regulated entities and the public containing information

necessary or helpful to the functioning of a credit market. Such reports may include recent information on credit transfer volumes, credit prices and price trends, and other information determined by the Executive Officer to be of value to market participants and the public. The Executive Officer shall establish, and may periodically modify, a schedule for the routine release of these reports.

(d) *Prohibited Transactions.* A trade involving, related to, or associated with any of the following is prohibited:

(1) Any manipulative or deceptive device;

(2) A corner or an attempt to corner the market for credits;

(3) Fraud, or an attempt to defraud any other entity;

(4) A false, misleading or inaccurate report concerning information or conditions that affects or tends to affect the price of a credit;

(5) An application, report, statement, or document required to be filed pursuant to this subarticle which is false or misleading with respect to a material fact, or which omits to state a material fact necessary to make the contents therein not misleading. A fact is material if it is reasonably likely to influence a decision by a counterparty, the Executive Officer, the Board, or the Board's staff; or

(6) Any trick, scheme, or artifice to falsify or conceal a material fact, including use of any false statements or representations, written or oral, or documents made by or provided to an entity through which transactions in credits are settled, or are cleared.

(7) Upon investigation pursuant to section 95495, the Executive Officer may cancel or reverse a credit transfer if a credit transfer is determined to be a prohibited transaction as per subsection (1) through (6) above. The Executive Officer shall notify the parties and identify the reasons for cancelling or reversing a credit transfer.

NOTE: Authority cited: Sections 38510, 38560, 38560.5, 38571, 38580, 39600, 39601, and 43018 Health and Safety Code; 42 U.S.C. section 7545, and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488. Entities Eligible to Apply for Fuel Pathways.

(a) Any person may apply to the Executive Officer for fuel pathway carbon intensity certification for the purpose of credit or deficit generation.

(b) *Joint Applicants.* Multiple entities may contribute site-specific data to a single pathway application. In these cases, the parties involved may either designate a single entity as the pathway applicant, or designate multiple entities as joint applicants on a single pathway. Applying as joint applicants allows each entity to maintain control of confidential data for the portions of the pathway they submit.

(1) Each joint applicant is subject to all requirements for pathway application, attestations, validation and verification, recordkeeping, pursuant to this subarticle, for the portion of the pathway they control.

(2) A single entity designated to submit data on behalf of multiple entities within a pathway does not relieve any other entity in the pathway from responsibility for ensuring that the data submitted on its behalf is accurate.

(c) *Transition to CA-GREET~~3~~4.0.*

(1) *Existing certified pathways.* ~~In the first quarter of 2021~~Fuel pathway holders must use the CA-GREET4.0 model or associated Tier 1 CI Calculators for 2024 annual Fuel Pathway Reports. Upon receiving a positive or qualified positive verification statement for each 2024 annual Fuel Pathway Report, the Executive Officer will ~~deactivate all fuel pathway codes in~~update and adjust the ~~LRT-CBTS~~CIs for ~~fuel pathways that were~~each previously certified ~~pursuant to a prior version of this subarticle, which used the CA-GREET2.0 model to determine CI, for the purpose of~~pathway to be the verified operational CI with an added conservative margin of safety if requested by the pathway holder. The adjusted CIs will be effective and available for reporting for fuel transactions ~~that occurred~~occurring on and after ~~December 31, 2020. Fuel pathway holders seeking to generate credits from these pathways after that date must follow the pathway application and certification process outlined in this subarticle to receive a certified pathway.~~January 1, 2026..

(A) *Existing Lookup Table Pathways.* Fuel reporting entities using Lookup Table pathways that do not require an application pursuant to section 95488.1(b)(1) will be automatically updated in the LRT-CBTS to the values in Table 7-1 on the effective date of this subarticle.

(2) *New Pathway Applications.* ~~Beginning in 2019 or the effective date of this subarticle, new fuel pathway applications using CA-GREET2.0 will not be processed. The requirement to obtain a third-party validation statement is effective for all pathway applications pending or submitted on or after January 1, 2020. All new pathway applications certified in 2019 will be validated by the Executive Officer~~Fuel pathway applications certified with a CI effective date of January 1, 2025 or later must use the CA-GREET4.0 or associated Tier 1 CI Calculators.

NOTE: Authority cited: Sections 38510, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.1. Fuel Pathway Classifications.

(a) For purposes of fuel pathway carbon intensity determination, all new LCFS fuel pathways certified after January 1, 2019 (or the effective date of this regulation) shall be classified as either a:

(1) Lookup Table pathway;

(2) Tier 1 pathway; or

(3) Tier 2 pathway, as described below.

(b) *Lookup Table Classification.* Pathways falling under this classification are the simplest pathways to use. The Board's staff develops Lookup Table pathway CI values using the CA-GREET~~3~~4.0 model. Input variables and assumptions are provided in the ~~CA-GREET3.0 Lookup Table Pathways --~~ Technical Support Documentation ~~(August 13, 2018),~~for Lookup Table Pathways [Date of adoption], which is incorporated herein by reference.

(1) *Lookup Table Pathways That Do Not Require a Fuel Pathway Application.* The following pathways are developed using average values for inputs into the CA-GREET~~3~~4.0 model, which are not expected to vary significantly across providers of the fuel. Entities seeking to generate credits under the pathways listed in 95488.1(b)(1)(A) through (E) may report fuel transactions directly in the LRT-CBTS without taking any action in the AFP.

(A) California Reformulated Gasoline Blendstock for Oxygenate Blending (CARBOB)

(B) California Ultra-low Sulfur Diesel (ULSD)

(C) Fossil Jet Fuel

~~(C)~~(D) Compressed Natural Gas

~~(D)~~(E) Fossil Propane

~~(E)~~(F) Electricity (California average grid)

(2) *Lookup Table Pathways That Require a Fuel Pathway Application.* Fuel pathway applicants for the following Lookup Table pathways must register

in the AFP and meet the application requirements of section 95488.5(b). Fuel pathway applicants may then report fuel transactions in the LRT-CBTS for the fuel pathways listed in 95488.1(b)(2)(A) through (~~F~~B).

(A) Electricity (100 percent zero-CI sources, which include: eligible renewable energy resources as defined in California Public Utilities Code sections 399.11-399.36, excluding biomass, biomethane, geothermal, and municipal solid waste)

(B) Electricity associated with smart charging pathway for EV charging and smart electrolysis pathway for hydrogen production through electrolysis

~~(C) Hydrogen (gaseous and liquefied) from central SMR of North American fossil-based natural gas~~

~~(D) Hydrogen (gaseous and liquefied) from central SMR of biomethane~~

~~(E) Hydrogen (gaseous) from electrolysis using California grid-average electricity~~

~~(F) Hydrogen (gaseous) from electrolysis using electricity from a zero-CI source as defined in (A) above~~

(c) *Tier 1 Classification.* The Tier 1 pathway classification applies to fuel pathway categories that the Board's staff has extensive experience evaluating. This classification includes fuel pathways for which the Executive Officer has identified a discrete set of site-specific inputs that can be modified to achieve CI changes. CI values for Tier 1 fuel pathways are determined using Board-approved ~~Simplified~~Tier 1 CI Calculators. The ~~Simplified~~Tier 1 CI Calculators provide a framework for applicants to enter monthly operational data inputs that are combined with emission factors and life cycle inventory data from the CA-GREET~~3~~4.0 model to calculate the pathway CI. The Tier 1 classification includes, but is not limited to, the following fuel pathways:

(1) Ethanol derived from starch or fiber in corn kernels or grain sorghum, and sugarcane;

(2) Biodiesel produced from feedstocks including but not limited to oilseed crop-derived oils; rendered animal fat, distiller's corn oil, distiller's sorghum oil, and used cooking oil;

~~(3)~~ Renewable ~~Diesel~~diesel, renewable naphtha, alternative jet fuel and renewable propane produced by hydrotreatment of feedstocks in a stand-alone reactor, including ~~but not limited to~~ oilseed crop-derived oils, rendered ~~tallow~~animal fat, distiller's corn oil, distiller's sorghum oil, and used cooking oil~~;~~

~~(4)~~(3) ~~LNG and L-CNG from North American fossil natural gas;~~, also known as Hydroprocessed Ester and Fatty Acid (HEFA) Fuels;

~~(5)~~(4) Biomethane from North American landfills, anaerobic digestion of wastewater sludge, dairy and swine manure, and food, urban landscaping waste, and other organic waste~~.~~; and

(5) Hydrogen produced from steam methane reforming of methane and electrolysis.

(d) *Tier 2 Classification.* The Tier 2 pathway classification shall apply to fuel pathways that the Board's staff has limited experience evaluating and certifying, including fuel pathways that are not currently in widespread commercial production. The Tier 2 classification includes all fuel pathways not included in Tier 1 or the Lookup Table pathways. The Tier 2 classification includes, but is not limited to the following fuel pathways:

(1) Cellulosic alcohols;

(2) Biomethane from sources other than those listed under the Tier 1 classification in (c)(5), above;

~~(3) Hydrogen pathways not found in the Lookup Table;~~

~~(4)~~(3) Electricity pathways not found in the Lookup Table;

~~(5)~~(4) Drop-in fuels (~~renewable~~biomass-derived hydrocarbons using processes such as gasification and pyrolysis and synthetic hydrocarbons) except for renewable ~~diesel~~hydrocarbon fuels produced from feedstocks described in section 95488.1(c)(3). This category includes fuels produced from low carbon feedstocks co-processed with fossil feedstocks in petroleum refineries;

~~(6)~~(5) Any fuel produced from unconventional feedstocks, such as algae oil;

~~(7)~~(6) Pathways classified as Tier 1 that are produced using innovative production methods. Innovative production methods include, but are not limited to:

(A) Use of one or more low-CI process energy sources.

(B) Use of carbon capture to produce an alternative fuel or carbon capture and sequestration where CO_2 capture occurs at the fuel production facilities. (Projects that utilize carbon capture and sequestration are subject to the provisions of section 95490).

(C) Pathways classified as Tier 1 that cannot be accurately modeled using the ~~Simplified~~Tier 1 CI Calculators.~~ Such pathways must meet the substantiality requirements of 95488.9(a).~~

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.2. Relationship Between Pathway Registration and Facility Registration.

After establishing an account in the Alternative Fuels Portal, per the requirements of section 95483.2(a), fuel pathway applicants must begin the application process by completing the facility and pathway registration through the AFP web portal. The provisions of 95488.2 do not apply to entities seeking to report fuel transactions for the fuel pathways listed in 95488.1(b)(1).

(a) *Production and Intermediate Facility Registration.* All production facilities and intermediate facilities from which site-specific operational data is relied upon in determining the CI score for a pathway must be registered in the AFP. All of the following fields that apply are required:

(1) Production company name and full mailing address.

(2) U.S. EPA Company ID for fuels covered by the federal RFS program. For fuels not covered by the RFS program, the AFP system will generate a Company ID.

(3) Company contact person's contact information.

(A) Name

(B) Title or position

(C) Phone number

(D) Mobile phone number

(E) Email address

(F) Company ~~web site~~website URL

(4) The fuel production facility name and address, for each proposed pathway.

(A) For biomethane to vehicle fuel pathways, the fuel production facility is the upgrading facility that purifies or otherwise produces biomethane that meets the applicable standards for pipeline or vehicle-quality natural gas.

(5) The names and addresses of any intermediate facilities, for each proposed pathway.

(A) For biomethane to vehicle fuel pathways, intermediate facilities that must be registered include the liquefaction facility, and the location where biogas or other biomethane feedstock is produced, if that location is not also the upgrading facility that is registered as the fuel production facility.

(B) For any feedstock whose supplier applies using site-specific CI data, the feedstock-processing facility must be registered as an intermediate facility for the fuel pathway in which the feedstock is utilized.

(6) U.S. EPA Facility ID for fuels covered by the federal RFS program. For fuels not covered by the RFS program, the Executive Officer will assign a Facility ID.

(7) Facility geographical coordinates (for each facility covered by the proposed pathways). Coordinates can be reported using either the latitude and longitude or the Universal Transverse Mercator coordinate systems.

(8) Facility contact person's contact information.

(A) Name

(B) Title or position

(C) Phone number

(D) Mobile phone number

(E) Email address

(9) Facility nameplate production capacity, or maximum expected throughput, in million gasoline gallon equivalents per year or other appropriate units. This information is required for each facility contributing site-specific data to the proposed pathways, including intermediate facilities in the supply chain.

(b) *Pathway Registration.* All of the following fields that apply are required.

(1) Consultant's contact information

(A) Name

(B) Title or position

(C) Legal company name

(D) Phone number

(E) Mobile phone number

(F) Email address

(G) ~~Web site~~Website URL

(2) Fuel type (renewable diesel, ethanol, etc.)

(3) Feedstock

(4) Brief pathway description (one to two sentences describing the technology, transport mode, and any non-standard co-products)

(5) Proposed pathway carbon intensity value

(6) Estimated annual fuel production quantity under the proposed pathway (estimated minimum, maximum, and average), in the applicable units specified for reporting in 95491(d)(1) through (5).

(7) *Classification.* The fuel pathway applicant must declare whether the proposed fuel pathway falls under the Lookup Table, Tier 1 or Tier 2 provisions of this regulation as specified in section 95488.1. The Executive Officer will evaluate the fuel pathway applicant's classification declaration and either approve or change it.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.3. Calculation of Fuel Pathway Carbon Intensities.

(a) *Calculating Carbon Intensities.* Fuel pathway applicants and the Executive Officer will evaluate all pathways based on life cycle greenhouse gas emissions per unit of fuel energy, or carbon intensity, expressed in gCO_2e/MJ. For this analysis, the fuel pathway applicant must use CA-GREET~~3~~4.0 model (including the ~~Simplified~~Tier 1 CI Calculators derived from that model) or another model determined by the Executive Officer to be equivalent or superior to CA-~~-~~-GREET~~3~~4.0~~.~~-.

(b) *CA-GREET~~3~~4.0.* The CA-GREET~~3~~4.0 model ~~(August 13, 2018)~~[Date of adoption] contains emission factors for calculating greenhouse gas emissions from site-specific inputs to fuel pathways and standard values for parts of the life cycle not included in applicant-specific data submission. The model is open source and publicly available at ~~http://www~~https://ww2.arb.ca.gov/~~fuels~~resources/documents/lcfs/~~lcfs.htm~~ life-cycle-analysis-models-and-documentation and is incorporated herein by reference. CA-GREET~~3~~4.0 includes contributions from the Oil Production Greenhouse Gas Estimator (~~OPGEE2.0~~OPGEE) model (for emissions from crude extraction) and Global Trade Analysis Project (GTAP-BIO) together with the Agro-Ecological Zone Emissions Factor (AEZ-EF) model for land use change (LUC).

Tier 1 ~~Simplified~~ CI Calculators, which incorporate emission factors and life cycle inventory data from the CA-GREET~~3~~4.0 model, are used to calculate carbon intensities for Tier 1 pathways. The ~~eight Simplified~~nine Tier 1 CI Calculators listed below are publicly available at ~~http://www~~https://ww2.arb.ca.gov/~~fuels~~resources/documents/lcfs/~~lcfs.htm~~ life-cycle-analysis-models-and-documentation and are incorporated herein by reference:

(1) Tier 1 ~~Simplified~~ CI Calculator for ~~Starch and Fiber*~~Corn or Sorghum Ethanol ~~(August 13, 2018)~~[Date of adoption]

(2) Tier 1 ~~Simplified~~ CI Calculator for Sugarcane~~-derived~~ Ethanol ~~(August 13, 2018)~~[Date of adoption]

(3) Tier 1 ~~Simplified~~ CI Calculator for Biodiesel ~~and Renewable Diesel (August 13, 2018)~~[Date of adoption]

(4) Tier 1 ~~Simplified~~ CI Calculator for ~~LNG and L-CNG from North American Natural Gas (August 13, 2018)~~Hydroprocessed Ester and Fatty Acid (HEFA) Fuels [date of adoption]

(5) Tier 1 ~~Simplified~~ CI Calculator for Landfill Biomethane ~~from North American Landfills (August 13, 2018)~~[Date of adoption]

(6) Tier 1 ~~Simplified~~ CI Calculator for ~~Biomethane from Anaerobic Digestion of~~ Wastewater Sludge ~~(August 13, 2018)~~Biomethane [Date of adoption]

(7) Tier 1 ~~Simplified CI Calculator~~CICalculator for ~~Biomethane from Anaerobic Digestion of~~ Dairy and Swine Manure ~~(August 13, 2018)~~Biomethane [Date of adoption]

(8) ~~Tier 1 Simplified~~Tier 1 CI Calculator for Organic Waste Biomethane [Date of adoption]

~~(8)~~(9) Tier 1 CI Calculator for ~~Biomethane from Anaerobic Digestion of Organic Waste (August 13, 2018)~~Hydrogen [Date of adoption]

(c) ~~*OPGEE2.0*~~*OPGEE*. The ~~OPGEE2.0~~OPGEE model is used to generate carbon intensities for crude oil used in the production of ultra-low sulfur diesel (ULSD) and California Reformulated Gasoline Blendstock for Oxygenate Blending (CARBOB).

(d) *Accounting for Land Use Change.* The Executive Officer calculates LUC effects for certain crop-based biofuels using the GTAP model (modified to include agricultural data and termed GTAP-BIO) and the AEZ-EF model. LUC values for six feedstock/finished biofuel combinations are provided in Table 6 below. The Executive Officer may use the same modeling framework to assess LUC values for other fuel or feedstock combinations, not currently found in Table 6, as part of processing a pathway application. Alternatively, the Executive Officer may require a fuel pathway applicant to use one of the values in Table 6, if the Executive Officer deems that value appropriate to use for a fuel or feedstock combination not currently listed in Table 6.

Table 6. Land Use Change Values for Use in CI Determination

Biofuel	***LUC (gCO_2/MJ)***
Corn Ethanol	19.8
Sugarcane Ethanol	11.8
Soy Biomass-Based Diesel	29.1
Canola Biomass-Based Diesel	14.5
Grain Sorghum Ethanol	19.4
Palm Biomass-Based Diesel	71.4

~~* Fiber in this case refers to corn and grain sorghum fiber exclusively.~~

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.4. Relationship of Pathway Carbon Intensities to Units of Fuel Sold in California.

(a) LCFS CIs represent the life cycle greenhouse gas emissions, expressed in a per-megajoule of finished-fuel energy basis, associated with long-term, steady-state fuel production operations. Actual CIs vary over time due to a variety of factors, including but not limited to seasonality, feedstock properties, plant maintenance, and unplanned interruptions and shutdowns. A fuel production operation will not be found to be in violation of its certified pathway based on CI unless a CI calculated from production data covering 24 months of operations is higher than the certified CI reported for that fuel in the LRT-CBTS system~~. A fuel pathway applicant~~ and the fuel pathway holder fails to satisfy an applicable deficit obligation for a verified CI exceedance specified in 95486.1(g). A fuel pathway holder may add a conservative margin of safety, of a magnitude determined by the applicant, to increase the certified CI above the operational CI calculated based on the data submitted in the initial fuel pathway application, to account for potential process variability and diminish the risk of non-compliance with the certified CI. Fuel producers labeling fuel sold in California with LCFS CIs (in product transfer or similar documents), and fuel reporting entities using those CIs to report the fuel in the LRT-CBTS system, must ensure that the fuel so labeled and so reported will be found to have a life cycle CI, as calculated from production data covering 24 months of operation, that is equal to or less than the CIs reported in the LRT-CBTS system and on product transfer documents. Fuel reporting entities shall not report fuel sales under any LCFS CI unless the actual CI of that fuel, calculated as described in this subarticle, is equal to or less than the LCFS CI under which sales of that fuel are reported in the LRT-CBTS system.

(b) *General Rule.* Except as provided in subdivision (c) below, fuel producers and fuel reporting entities covered by this regulation order must associate a CI with each unit of fuel sold in California. In general, fuel producers and fuel reporting entities shall assign all units of fuel produced while a given set of production parameters is in effect the same CI, regardless whether those units will be sold in California. For example, where a producer uses both biogas and natural gas as process fuel, the producer shall assign all units produced a single CI that reflects the mix of process fuels used to produce those units; the producer shall not assign the units destined for the California market a CI associated only with the use of biogas.

A producer or fuel reporting entity may assign a different certified CI only when one or more production parameters changes. Following that change, all units produced while the new set of production parameters is in effect have the new CI, regardless of whether those units will be sold in California.

(c) *Exceptions.* Under the following two sets of conditions, a producer or fuel reporting entity may assign different CIs to portions of the fuel produced while a given set of production parameters is in effect. Those conditions are:

(1) Two or more feedstocks are being simultaneously fed into the production process. For example, a renewable diesel production facility may feed a mixture of soy oil, ~~tallow~~animal fat, and used cooking oil into its production

process. Or a hydrogen production facility may use both natural gas and renewable natural gas as feedstock for steam methane reformation.

(2) Two or more co-products are being produced simultaneously. For example, a corn ethanol plant may dry only a portion of the distiller's grains it produces; a portion of the distiller's grains produced is sold dry, and the remainder is sold wet.

(d) *How to Use the Multiple Feedstock Exception.* When two or more feedstocks are being simultaneously fed into the production process, the producer or fuel reporting entity shall associate a portion of the fuel produced with each feedstock, using the production facility's average production yield and one of the methods provided in section 95491(d)(1)(C). The producer or fuel reporting entity must then label each feedstock-specific subdivision of the total fuel quantity produced with the certified CI associated with that feedstock.

(e) *How to use the Multiple Co-Product Exception.* When two or more co-products are being simultaneously produced, the producer or fuel reporting entity may label the fuel associated with those co-products one of two ways:

(1) If the production facility has available to it a single CI reflective of the current set of operational conditions (including the production of two or more co-products, in the proportions currently being produced), the producer or fuel reporting entity may label the facility's entire production run with that CI.

(2) If the production facility has available to it separate CIs associated with the production of each co-product, the producer or fuel reporting entity may label portions of the fuel produced with the certified CIs associated with each co-product, in proportion to the co-product stream fraction that each co-product comprises. The producer or fuel reporting entity shall calculate the co-product proportions on an appropriate basis to conform to the life cycle approach used for the fuel pathway.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.5. Lookup Table Fuel Pathway Application Requirements and Certification Process.

(a) *Applicability.* A fuel reporting entity may use a Lookup Table pathway if the Lookup Table (Table 7-1 in section 95488.5(e)) contains a fuel pathway that closely corresponds to the actual physical fuel production pathways used to produce the fuel in question. A fuel's actual physical fuel production pathway corresponds closely with a Lookup Table pathway when it is consistent with the Lookup Table pathway in all the areas listed in (1) through (6) below:

(1) Feedstocks used to produce the fuel;

(2) Fuel and feedstock production technology;

(3) Regions in which feedstocks and finished fuel are produced;

(4) The modes used to transport feedstocks and finished fuel and the transport distances involved;

(5) The types and amounts of thermal and electrical energy consumed in both feedstock and finished fuel production. This applies both to the energy consumed in the production process and to the upstream energy consumed (e.g., fuels used to generate electricity; energy consumed to produce natural gas, etc.); and

(6) The CI of the fuel pathway applicant's product must be lower than or equal to the Lookup Table pathway CI. If the Executive Officer determines the product has an actual CI that is likely to be higher than the Lookup Table CI value, the applicant may apply for a Tier 2 pathway.

(b) *Lookup Table Pathway Application Requirements.* Entities seeking approval to report fuel transactions using the fuel pathways listed in 95488.1(b)(2)(A) through (~~F~~B) (electricity generated from one of the zero-CI sources listed in 95488.1(b)(2)(A~~),~~) and smart charging or smart electrolysis~~, and all hydrogen Lookup Table pathways)~~ must submit the fuel pathway applicant attestation letter pursuant to the requirements of 95488.8(a) and meet the following requirements:

(1) The following information must be submitted with applications for the Lookup Table pathway for electricity generated from zero-CI sources and smart charging or smart electrolysis:

(A) For directly supplied zero-CI electricity, an applicant must indicate the locations of electricity generation equipment, meters, meter ID numbers, and identify any other users of the electricity.

(B) For zero-CI electricity supplied using book-and-claim accounting, contracts and invoices are required to demonstrate that the electricity meets the requirements of section 95488.8(i)(1).

(C) For smart charging or smart electrolysis electricity, records demonstrating the quantity of electricity dispensed during each hour for the latest quarter.

~~(2) The following information shall be submitted with applications for any hydrogen Lookup Table pathways:~~

~~(A) Submittal of the fuel pathway applicant attestation letter affirms that the applicant has reviewed and understood the pathway conditions described in the Lookup Table Pathways -- Technical Support Documentation specified in section 95488.5(e), and attests that their actual physical pathway is consistent with the Lookup Table pathway in the areas listed in 95488.5(a). Any exceptions, whether likely to result in a higher or lower CI, must be noted in the attestation letter.~~

~~(B) The completed NREL National Fuel Cell Technology Evaluation Center's Hydrogen Station Infrastructure Data Template covering three months of operation, if available, is required.~~

~~(3) The following information must be submitted with all Lookup Table pathway applications for renewable hydrogen:~~

~~(A) Contracts and invoices meeting the requirements of 95488.8(h), or 95488.8(i), are required to substantiate type and source of renewable input used to produce the fuel.~~

(c) *Completeness Check for Lookup Table Fuel Pathway Applications.* For the Lookup Table pathways listed in 95488.1(b)(2)(A) through (F), the Executive Officer will evaluate submitted information for completeness. The Executive Officer shall contact the applicant regarding any lack of required information or clarification of submitted information. If the fuel pathway applicant does not provide a satisfactory response to address the request within ~~15 business~~14 days, the Executive Officer will reject the pathway application. Applicants whose applications are rejected may submit a new application that addresses deficiencies highlighted during the earlier review.

(d) *Updates to Electricity Pathways.*

(1) *Annual Update to California Average Grid Electricity Pathway.* In order to reflect the rapidly evolving portfolio of electricity generating resources in California, the Executive Officer will update the "California Average Grid Electricity Used as a Transportation Fuel in California" Lookup Table pathway CI value on an annual basis. The Executive Officer will use the methodology described in the supporting document specified in section 95488.5(e) to determine the carbon intensity. The CA-GREET~~3~~4.0 model inputs and data sources used to calculate the CI will be posted for 45 days for public comment prior to certification. If these comments require significant revision of the originally published pathway, an updated pathway will be posted for public comment. The updated Lookup Table pathway CI value will be available for reporting in the quarter in which it is certified.

(2) *Update to Smart Charging Electricity Pathways.* In order to reflect the seasonal variation of electricity generating resources in California and to maintain accounting consistency with the CI of the California Average Grid Electricity pathway, the Executive Officer will use the methodology described in the supporting document specified in section 95488.5(e) and the public comment process described in 95488.5(d)(1) to update the smart charging or smart electrolysis pathway CIs in Table 7-2.

(e) ~~The following supporting document, which is incorporated herein by reference~~The Technical Support Documentation for Lookup Table Pathways, describes the methodology and data sources used to determine the carbon intensity values for the fuel pathways, shown below in Table 7-1, and the hourly windows for smart charging or smart electrolysis electricity pathways, shown below in Table 7-2:

~~Industrial Strategies Division, California Air Resources Board. August 13, 2018. CA-GREET3.0 Lookup Table Pathways Technical Support Documentation.~~

Table 7-1. Lookup Table for Gasoline and Diesel and Fuels that Substitute for Gasoline and Diesel[2]

Fuel	***Fuel Pathway Code***	***Fuel Pathway Description***	***Carbon Intensity Values (gCO_2e/MJ)***
CARBOB	CBOB	CARBOB -- based on the average crude oil supplied to California refineries and average California refinery efficiencies	100.~~82~~60
Diesel	ULSD	ULSD -- based on the average crude oil supplied to California refineries and average California refinery efficiencies	~~100.45~~105.76
Fossil Jet Fuel	FJF	Fossil Jet Fuel – based on the average crude oil supplied to California refineries and average California refinery efficiencies	89.43
Compressed Natural Gas	CNGF	Compressed Natural Gas from Pipeline Average North American Fossil Natural Gas	~~79.21~~81.18
Propane	PRPF	Fossil LPG from crude oil refining and natural gas processing used as a transport fuel	~~83.19~~81.43
	ELCG	California average grid electricity used as a transportation fuel in California	~~93.75~~81.00 (and subject to annual updates)

Fuel	***Fuel Pathway Code***	***Fuel Pathway Description***	***Carbon Intensity Values (gCO_2e/MJ)***
Electricity	ELCR	Electricity that is generated from 100 percent zero-CI sources used as a transportation fuel in California	0.00
	ELCT	Electricity supplied under the smart charging or smart electrolysis provision	(See Table 7-2)
~~Hydrogen~~	~~HYF~~	~~Compressed H2 produced in California from central SMR of North American fossil-based NG~~	~~117.67~~
	~~HYFL~~	~~Liquefied H2 produced in California from central SMR of North American fossil-based NG~~	~~150.94~~
	~~HYB~~	~~Compressed H2 produced in California from central SMR of biomethane (renewable feedstock) from North American landfills~~	~~99.48~~
	~~HYBL~~	~~Liquefied H2 produced in California from central SMR of biomethane (renewable feedstock) from North American landfills~~	~~129.09~~
	~~HYEG~~	~~Compressed H2 produced in California from electrolysis using California average grid electricity~~	~~164.46~~
	~~HYER~~	~~Compressed H2 produced in California from electrolysis using zero-CI electricity~~	~~10.51~~

[2] For comparison on an equivalent basis (gCO_2e per MJ of conventional fuel displaced), the CIs listed in Tables 7-1 and 7-2 must be divided by the EER in Table 5 for the appropriate fuel-vehicle combination. The EER-adjustment is made when fuel quantities are reported in the LRT-CBTS to calculate the correct number of credits or deficits, using the equations in 95486.1(a).

(f) *Smart Charging or Smart Electrolysis Lookup Table Pathways.* The Executive Officer will calculate the following carbon intensity lookup table that may be used for reporting electric vehicle charging and hydrogen produced via electrolysis in California. For hydrogen production through electrolysis outside of California, an applicant must provide, through the Tier 2 application process, a comparable method to determine smart electrolysis carbon intensity values for the grid electricity in the state or region where hydrogen is produced.

Updates to this table will be provided at least annually on the LCFS ~~web site~~website.

Table 7-2. Calculated Smart Charging or Smart Electrolysis Carbon Intensity Values for ~~2019~~[3]2023 (in $gCO2_e$/MJ)[3]

Hourly Window	~~*CI (gCO_2e/MJ)*~~*Q1*	*Q2*	*Q3*	*Q4*

(g) *Executive Officer Review of CI Selection.* A fuel reporting entity's choice of carbon intensity value from the Lookup Table is subject in all cases to Executive Officer review. The Executive Officer may request any documentation necessary to determine that the pathway conforms to the Lookup Table pathway.

(1) If the Executive Officer has reason to believe that a fuel reporting entity's Lookup Table choice is not the CI value that most closely corresponds to its actual pathway CI, the Executive Officer shall notify the entity through the LRT-CBTS to choose a different pathway from the Lookup Table; or

(2) If the Executive Officer has reason to believe that the Lookup Table does not contain a fuel pathway that closely corresponds with the actual fuel pathway, the Executive Officer will notify the entity accordingly and the fuel reporting entity will not be allowed to use the Lookup Table to

Inserted Cells

Inserted Cells

Inserted Cells

generate credits or deficits. In that case, the entity may apply for a Tier 1 or Tier 2 pathway.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.6. Tier 1 Fuel Pathway Application Requirements and Certification Process.

(a) *Documentation Required for Tier 1 Pathways.* A fuel pathway applicant may apply for a Tier 1 pathway using the provisions set forth in this section. After satisfying all requirements for pathway and facility registration in 95488.2, the applicant must submit the following information to the Executive Officer for consideration of a Tier 1 pathway CI.

(1) *~~Simplified~~Tier 1 CI Calculator.* A fuel-specific ~~Simplified~~Tier 1 CI Calculator populated with all applicable site-specific operational data inputs is required. The period covered shall be the most recent 24~~-~~-month period of operation~~.~~ or at least three months of operation for provisional fuel pathway applications. Tier 1 applications must not have an interval of greater than 3 months between the end of the reported operational data month and the date of submission. Fields that require site-specific inputs are marked in the ~~Simplified~~Tier 1 CI Calculator. Site-specific inputs include, but are not limited to, the monthly quantity of all feedstocks consumed in the fuel production facility, the electricity generation mix of the subregion(s) where feedstock and fuel production occur, the types and monthly quantities of all energy used in the production of the fuel, and the monthly quantities of fuel produced.

(A) The ~~Simplified~~Tier 1 CI Calculators include appropriate LUC or other indirect carbon intensity modifiers from Table 6 when applicable.

(B) Applicants must follow the instructions for completing site-specific inputs in the ~~Simplified~~Tier 1 CI Calculators found in the Tier 1 ~~Simplified~~ CI Calculator Instruction Manuals. . The Tier 1 CI Calculator Instruction Manuals listed below are publicly available at https://ww2.arb.ca.gov/resources/documents/lcfs-life-cycle-analysis-models-and-documentation~~Manual (August 13, 2018),~~ and are herein incorporated ~~herein~~ by reference~~.~~:

1. ~~Industrial Strategies Division, California Air Resources Board. August 13, 2018.~~ Tier 1 ~~Simplified~~ CI Calculator for

Corn or Sorghum Ethanol - Instruction Manual~~.~~ [date of adoption]

2. Tier 1 CI Calculator for Sugarcane Ethanol - Instruction Manual [date of adoption]

3. Tier 1 CI Calculator for Biodiesel - Instruction Manual [date of adoption]

4. Tier 1 CI Calculator for Hydroprocessed Ester and Fatty Acid (HEFA) - Instruction Manual [date of adoption]

5. Tier 1 CI Calculator for Landfill Biomethane - Instruction Manual [date of adoption]

6. Tier 1 CI Calculator for Wastewater Sludge Biomethane - Instruction Manual [date of adoption]

7. Tier 1 CI Calculator for Dairy and Swine Manure Biomethane - Instruction Manual [date of adoption]

8. Tier 1 CI Calculator for Organic Waste Biomethane - Instruction Manual [date of adoption]

9. Tier 1 CI Calculator for Hydrogen - Instruction Manual [date of adoption]

(C) All applicants using grid electricity must choose electrical generation energy mixes from among the subregions in CA~~-~~-GREET~~3~~4.0 and the ~~Simplified~~Tier 1 CI Calculators, if applicable. The options include the 26 subregions defined in the U.S. EPA~~'~~'s Emissions and Generation Resource Integrated Database with year 20214 data (~~eGRID2014v2, released on February 27, 2017~~eGRID2021, January 30, 2023), and a national grid mix for Brazil and Canada.

1. *User-defined Process Energy Option.* Applicants whose fuel production facilities or feedstock source regions are located in an area for which there is no corresponding subregion included in the ~~Simplified~~Tier 1 CI Calculator may select the user-defined option, and shall consult with the Executive Officer for approval of the data prior to submitting an application.

(2) *Supplemental Information.* Supporting evidence for specified inputs to the CI calculator can be uploaded to the AFP as a supplemental information

document, as needed. Supplemental information is required under the following circumstances:

(A) If an alternative form of process energy supplied directly to the production facility are used, evidence must be provided to identify the source, to demonstrate that it is delivered directly to the production facility, and to determine the carbon intensity of the process energy input.

(B) If the fuel pathway applicant selects user-defined emission factors for regions not currently included in the ~~Simplified~~Tier 1 CI Calculator, to reflect the grid electricity resource mix, crude and natural gas for that region. Supporting evidence and data sources for these emission factors must be provided.

(C) If the fuel produced or any by-products or co-products receive additional processing after they leave site, such as additional distiller's grains drying or fuel distillation, supporting evidence of the energy consumed for those processes must also be submitted.

(D) If the fuel production facility is co-located with one or more unrelated facilities, and energy consumption data (or other data required in calculating CI) are not separately available for the fuel production facility, the applicant shall install automated metering equipment with electronic data archival to enable an Executive Officer accredited verification body to confirm energy consumption data for the 24 months of operation submitted in the application. The metering should be capable of recording daily total energy consumption data. The same requirements apply if a single facility includes multiple operations including fuel production.

(E) Other information to facilitate staff review may also be included as part of the supplemental information.

(b) *Certification Process for Tier 1 Pathway Applications*.

(1) *Validation.* The applicant must seek the services of an Executive Officer accredited verification body to complete a pathway validation as specified in section 95500. A positive or qualified positive validation statement must be received by the Executive Officer from the verification body in order for CARB's completeness review, evaluation, and certification of the pathway application to proceed. In cases where a single applicant or a joint applicant does not complete validation, the application will be denied without prejudice. In cases where ~~an applicant cannot complete~~ validation cannot be completed within six months of ~~submitting an~~the verification body receiving the application from CARB or an applicant receives an adverse validation statement, the application will be denied without

prejudice. Fuel pathway applicants whose applications are denied without prejudice may submit new applications with the most current operational data pursuant to section 95488.6(a)(1).

(2) *Completeness Review.* Upon receipt of a positive or qualified positive validation statement, the Executive Officer will conduct a completeness review of the Tier selection to ensure the pathway meets the requirements for Tier 1, and evaluate if the inputs to the ~~Simplified~~Tier 1 CI Calculator are complete.

(A) *Application Complete*. If the Executive Officer deems complete the applicant's ~~Simplified~~Tier 1 CI Calculator and supplemental information, the fuel pathway applicant shall be notified as such. The application deemed complete quarter is the quarter in which the application is returned by the verification body to the Executive Officer after the completion of validation with a positive or qualified positive statement.

(B) *Application Incomplete.* If the Executive Officer deems the ~~Simplified~~Tier 1 CI Calculator and supplemental information incomplete, the Executive Officer will reject the pathway application without prejudice and inform the fuel pathway applicant of the rationale for rejection. Applicants whose applications are rejected may submit a new application that addresses deficiencies highlighted during the earlier review.

(3) *Certification.* The Executive Officer may certify or reject a pathway application.

(A) The Executive Officer will evaluate the application to determine whether it has met all requirements necessary for certification. At any point during the evaluation process, the Executive Officer may request in writing additional information or clarification from the applicant.

(B) If the Executive Officer determines the application has met all requirements necessary for certification, the Executive Officer will complete a pathway summary of the inputs, the facility average fuel production yield, CI results, and any applicable limitations or conditions. Upon certification of a Tier 1 application, the pathway will be available for reporting for the quarter in which it was deemed complete.

(C) Upon certification, the fuel pathway applicant(s) becomes the fuel pathway holder(s) for the certified fuel pathway and is subject to the requirements of 95488.10, and any limitations or conditions identified by the Executive pursuant to (3)(B) above, in order for that pathway to remain eligible for reporting and credit generation purposes.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.7. Tier 2 Fuel Pathway Application Requirements and Certification Process.

(a) *Documentation Required for Tier 2 Pathways.* A fuel pathway applicant may apply for a Tier 2 pathway using the provisions set forth in this section. After satisfying all requirements for pathway and facility registration in 95488.2, the applicant must submit the following information to the Executive Officer for consideration of a Tier 2 pathway CI:

(1) *CA-GREET Model.* A copy of the CA-GREET~~3~~4.0 spreadsheet prepared for the life cycle analysis of the proposed fuel pathway. Tier 2 pathway carbon intensities must be calculated using the CA-~~GREET3.0 model, with the most current 24 months of operational data~~GREET4.0 model, unless the Executive Officer has approved the use of a method or model that the Executive Officer has determined is at least equivalent to the calculation methodology used by CA-~~GREET3.0. The CA-GREET3~~GREET4.0. The data period covered shall be the most current 24-month period of operation or at least three months of operation for provisional pathway applications. Tier 2 applications must not have an interval of greater than 3 months between the end of the operational data month and the date of submission. The CA-GREET4.0 model shall include appropriate LUC or other indirect carbon intensity modifier from Table 6 when applicable.

(2) *Life Cycle Analysis Report.* A life cycle analysis report that describes the full fuel life cycle, and describes in detail the calculation of the fuel pathway CI. The report shall contain sufficient detail to allow the Board's staff to replicate the CI calculated by the applicant. All inputs to, and outputs from, the fuel production process that contribute to the life cycle CI must be described in the life cycle analysis report. These inputs and outputs must then be fully accounted for in the calculation of the fuel pathway CI. The life cycle analysis report shall include the following information:

(A) A detailed description of the full fuel production process. The description shall include:

1. A description of the full well-to-wheels fuel life cycle, including the locations where each primary step in the fuel

life cycle occurs. This description shall identify where the system boundary was established for the purposes of performing the life cycle analysis on the proposed pathway. The discussion of the system boundary shall be accompanied by a schematic depicting the system boundary. That schematic shall show all feedstock and fuel production units that are included in the system boundary, as well as all material and energy flows across the system boundary. Any feedstock or fuel production units that have been excluded from the system must be shown on the schematic, and must be explicitly discussed in the narrative description of the full fuel life cycle.

2. A description of all fuel production feedstocks used, including all pre-processing to which feedstocks are subject. For fuels utilizing agricultural crops for feedstocks, the description shall include the agricultural practices used to produce those crops. This discussion shall cover energy and chemical use, typical crop yields, feedstock harvesting, transport modes and distances, storage, and pre-processing (such as drying or oil extraction).

3. A description of all material inputs to the production process not covered in 2, above. These include, but are not limited to enzymes, nutrients, chemicals, catalysts, and microorganisms.

4. A description of the transportation modes used throughout the fuel life cycle. This discussion must identify origins and destinations, cargo carrying capacities, fuel shares, and the distances traveled for each transport mode.

5. A description of all facilities and process units involved in the production of fuel under the proposed pathway.

6. A list of all combustion-powered equipment, along with their respective capacities, sizes, or rated power, and type and amount of fuel combusted, throughout all phases of the fuel life cycle over which the fuel pathway applicant exercises control.

7. A quantitative discussion of the thermal and electrical energy consumption that occurs throughout all phases of the fuel life cycle over which the applicant exercises control. All fuels used (natural gas, biogas, coal, biomass, etc.) must be identified and use rates quantified. The regional electrical energy generation fuel mix used in the CA~~-~~-GREET~~3~~4.0

analysis must be identified. Internally generated power such as cogeneration and combined heat and power must also be described. All fuel pathway applicants using grid electricity must choose electrical generation energy mixes from among the subregions in CA-~~-~~GREET~~3~~4.0, if applicable. The options include the 26 subregions defined in eGRID20~~14v~~21, and a national grid mix for Brazil and Canada. Applicants whose fuel production facilities or feedstock source regions are located in an area for which there is no corresponding subregion included in CA-GREET~~3~~4.0 must enter user-defined energy resources and submit the source of the data utilized to the Executive Officer for approval.

8. A description of all co-products, byproducts, and waste products associated with production of the fuel. That description shall extend to all processing, such as drying of distiller's grains, applied to these materials after they leave the fuel production process, including processing that occurs after ownership of the materials passes to other parties. Moreover, if a co-product credit is claimed for a co- or by-product, that credit must reflect all post-fuel-production processing steps covered by this section. If a co-product (e.g., electricity) is exported across the fence line, details of the quantity of energy transferred on a daily basis must be monitored using data systems with electronic archival.

(B) A detailed description of the calculation of the pathway CI. This description must provide clear, detailed, and quantitative information on process inputs and outputs, energy consumption, greenhouse gas emissions generation, and the final pathway carbon intensity, as calculated using CA-GREET~~3~~4.0. Important intermediate values in each of the primary life cycle stages shall be shown. Those stages include but are not limited to feedstock production and transport; fuel production, fuel transport, and dispensing; co-product production, transport and use; waste generation, treatment and disposal; and fuel use in a vehicle. This description shall include, at a minimum:

1. A table showing all CA-GREET~~3~~4.0 input values entered by the applicant. The worksheet, row, and column locations of the cells into which these inputs were entered shall be identified. In combination with the modifications identified in subsection (B)2. below, this table shall enable the Executive Officer to enter the reported inputs into a copy of CA-GREET~~3~~4.0 and to replicate the carbon intensity results reported in the application.

2. A detailed discussion of all modifications other than those covered by subsection (B)1. above, made to the CA-~~-~~GREET~~3~~4.0 spreadsheet. This discussion shall allow the Executive Officer to duplicate all such modifications and, in combination with the inputs identified in subsection (B)1. above, replicate the carbon intensity results reported in the application.

3. Documentation of all CA-GREET~~3~~4.0 values used in the carbon intensity calculation process.

4. A detailed description of all supporting calculations that were performed outside of the CA-GREET~~3~~4.0 spreadsheet.

(C) Descriptions of all co-located facilities, which in any way utilize outputs from, or provide inputs to, the fuel production facility. Such co-located facilities include but are not limited to cogeneration facilities, facilities that otherwise provide heat or electrical energy to the fuel production process, facilities that process or utilize co-products such as distillers grains with solubles, and facilities which provide or pre-process feedstocks or thermal energy fuels. If energy is supplied to the fuel production facility by a co-located cogeneration plant and that plant also supplies energy to other facilities, those other facilities must be identified and described. For facilities that are co-located with other production facilities or utilize multiple processing operations in addition to fuel production, demonstration of energy use should conform to section 95488.6(a)(2)(D).

(D) A list of references covering all information sources used in the preparation of the life cycle analysis. All reference citations in the application shall include standard in-text parenthetical citations stating the author's last name and date of publication. Each in-text citation shall correspond to complete publication information provided in the list of references. Complete publication information shall at a minimum, identify the author(s), title of the referenced document (and of the article within that document, if applicable), publisher, publication date, and pages cited. For internet citations, the reference shall include the universal resource locator (URL) address of the citation, as well as the date the ~~web site~~website was last accessed.

(E) One or more process flow diagrams that, singly or collectively, depict the complete fuel production process. Each piece of equipment or stream appearing on the process flow diagram shall include data on its energy and materials balance, along with any other critical information such as operating temperature, pH, rated capacity, etc.

(F) A copy of the federal Renewable Fuel Standard (RFS) Third Party Engineering Review Report required pursuant to 40 CFR part 80.1450, if available. If the RFS engineering report is not available, the Life Cycle Analysis Report shall explain why it is not available.

(G) A copy of the federal Renewable Fuel Standard (RFS) Fuel Producer Co-products Report as required pursuant to 40 CFR 80.1451(b)(1)(ii)(M)-(N), if available.

(3) *Tier 2 Pathways for EER-Adjusted Carbon Intensity.* Applicants supplying fuel for a transportation application that is not included in Table 5 may apply for an EER-adjusted carbon intensity for reporting and credit generation purposes.

(A) *Documentation Requirements.* To request an EER-adjusted carbon intensity, the applicant must provide the following in addition to subsections (1) and (2) above:

1. A letter of intent to request an EER-adjusted CI and why the EER values provided in Table 5 do not apply.

2. Supplemental information including a detailed description of the methodology used, all assumptions made, and all data and references used for calculation of the proposed EER-adjusted CI value. The methodology used must compare the useful output from the alternative fuel technology to that of comparable conventional fuel technology.

3. If the applicant plans to use a Lookup Table pathway to request an EER-adjusted CI then subsections (1) and (2) above do not apply.

(b) *Scientific Defensibility.* For a proposed Tier 2 pathway to be certifiable by the Executive Officer, the fuel pathway applicant must demonstrate that the life cycle analysis prepared in support of the pathway application is scientifically defensible in the Executive Officer's best engineering and scientific judgment.

For purposes of this regulation, “scientifically defensible” means the method for calculating the fuel's carbon intensity may rely on, but is not limited to, publication of the proposed pathway in a major, well-established and peer-reviewed scientific journal (e.g., the International Journal of Life Cycle Assessment; The Journal of Cleaner Production, Biomass and Bioenergy).

(c) *Documents for Public Review.* Section 95488.8(c) contains requirements for submittal of documents that contain confidential business information and redacted versions for posting to a public LCFS ~~web site~~website. Public information including emissions data, must not be redacted.

(d) *Certification Process for Tier 2 Pathway Applications*.

(1) *~~Completeness~~Pre-validation Review.* The Executive Officer will evaluate the LCA Report, CA-GREET~~3~~4.0 model, and all submitted documentation for completeness in order to conduct a comprehensive evaluation of the pathway application and confirm that the methods presented are appropriate from an LCA perspective and confirm that the fuel pathway application meets the requirements for the Tier 2 classification. The Executive Officer may contact the fuel pathway applicant for an explanation of any questionable inputs, methods or lack of information in the application. The applicant must respond and address the request within ~~15 business~~14 days, as provided in subsection (1)(B) below:

(A) *Application ~~Complete.~~Ready for Validation.* If the Executive Officer deems the Tier 2 application and LCA report ~~complete and appropriate~~ready for validation, the applicant will be notified accordingly and provided with a list of site-specific inputs required for validation. The fuel pathway applicant must ~~then~~ seek the services of an Executive Officer accredited verification body for validation as specified in section 95500 before the application can be accessed by the verification body in LRT-CBTS.

(B) *Application ~~Incomplete.~~not Ready for Validation.* If the Executive Officer deems the Tier 2 application ~~incomplete~~not ready for validation, and the applicant does not provide a satisfactory response to address the deficiencies within ~~15 business~~14 days, the Executive Officer will reject the pathway application without prejudice and inform the applicant of the rationale for rejection. Fuel pathway applicants whose applications are rejected may submit a new application with the most current operational data pursuant to section 95488.7(a)(1) that addresses deficiencies highlighted during the earlier review.

(2) *Site-specific Inputs.* Tier 2 pathways are expected to be unique with no predetermined life cycle analysis profile; therefore, such pathways do not include a defined set of predetermined site-specific inputs that are required to be provided in the annual Fuel Pathway Report and must be verified. The Executive Officer shall identify all site-specific inputs for a Tier 2 pathway and make this available for review by the fuel pathway applicant. This includes any non-numerical parameters or conditions which must be checked by the verifier. The applicant has ~~15 business~~14 days to review and accept the Executive Officer's proposed site-specific inputs. If there is disagreement, the applicant may suggest modified site-specific inputs within this period. The Executive Officer will review the

applicant's suggested inputs and present to the applicant a final list of site-specific inputs. The applicant then has 7~~ business~~ days to accept the updated site-specific inputs. If the applicant disagrees with the final list of site-specific inputs, the applicant may withdraw the pathway application; if not withdrawn, the application will be rejected by the Executive Officer. The Executive Officer~~'~~'s decision regarding the final list of site-specific inputs for Tier 2 pathways is binding.

(3) *Validation.* A positive or qualified positive validation statement must be received by the Executive Officer from the verification body in order for CARB~~'~~'s evaluation and certification of the pathway application to proceed. The application deemed complete quarter is the quarter in which the application is returned by the verification body to the Executive Officer after the completion of validation with a positive or qualified positive statement. In cases where a single applicant or a joint applicant does not complete validation, the application will be denied without prejudice. In cases where ~~an applicant cannot complete ~~validation cannot be completed within six months of ~~submitting an~~the verification body receiving the application~~,~~ from CARB or an applicant receives an adverse validation statement, the application will be denied without prejudice. Fuel pathway applicants whose applications are denied without prejudice may submit new applications with the most current operational data pursuant to section 95488.7(a)(1).

(4) *Engineering Review.* The Executive Officer has the authority to request any supporting documentation to investigate specific inputs in the fuel pathway applicant's submitted CA-GREET~~3~~4.0 model. The Executive Officer will evaluate all applications against the following criteria:

(A) The Executive Officer will attempt to replicate the applicant's carbon intensity calculations. Replication will proceed as follows:

1. Starting with a copy of CA-GREET~~3~~4.0 that has not previously been used for calculations associated with the proposed pathway, the Executive Officer will enter all the inputs reported by the applicant.

2. The Executive Officer will then apply all CA-GREET~~3~~4.0 modifications reported by the applicant.

3. If the Executive Officer is able to duplicate the applicant's results, the Executive Officer will proceed to subsection (B) below. If the Executive Officer is not able to duplicate the applicant's CA-GREET~~3~~4.0 results, the application shall be denied.

(B) The Executive Officer will evaluate the validity of all inputs and methods not directly related to energy consumption used to calculate the applicant's CI. If any of those inputs are found to be invalid, the application will be denied.

(C) The Executive Officer will complete a pathway summary containing the site-specific inputs, the facility average fuel production yield, CI results, and any applicable limitations or conditions. The pathway summary, with CBI redacted, will be posted to the LCFS ~~web site~~website for public review.

(5) *Public Comment Period.* The application package, containing the Executive Officer's pathway summary and the documents prepared by the applicant for public review, will be posted to the LCFS ~~web site~~website for public comment once the Executive Officer completes a final check of the pathway application to ensure it has met all requirements for certification.

(A) Comments will be accepted for ~~10 business~~14 days following the date on which the application was posted. Only comments related to potential factual or methodological errors will require responses from the fuel pathway applicant. The Executive Officer will forward to the applicant all comments identifying potential factual or methodological errors. In response, the applicant must either:

1. Make revisions to its application that respond to the comments received and submit those revisions to the Executive Officer. The revised application packet must include a detailed discussion of the revisions made. The discussion must clearly delineate how each comment is related to a responsive revision. The revisions submitted must be approved by the Executive Officer before the application can be certified;

2. Submit a detailed written response to the Executive Officer explaining why no revisions are necessary. The response submitted by the fuel pathway applicant must be approved by the Executive Officer before the application can be certified;

3. As specified in subsection 1, revise portions of the application in response to a subset of the comments received, and, as specified in subsection 2., submit a written response explaining why the remaining comments do not warrant revisions; or

4. Withdraw the application.

(B) The Executive Officer will evaluate the fuel pathway applicant's responses to the comments received, and determine whether they have adequately addressed the potential factual or methodological errors identified in those comments. If deemed adequate, those responses will be posted to the LCFS ~~web site~~website, and the pathway (revised as needed) will be certified and posted to the LCFS ~~web site~~website. If the applicant fails to submit responses or the responses are deemed inadequate, the application will be denied.

(C) If no public comments are received, the application will be certified and posted to the LCFS ~~web site~~website.

(6) *Certification.* The Executive Officer may certify or reject a pathway application. Upon certification of a Tier 2 application, the pathway will be available for reporting for the quarter in which it was deemed complete. Upon certification, the fuel pathway applicant(s) becomes the fuel pathway holder(s) for the certified fuel pathway and is subject to the requirements of 95488.10 in order for that pathway to remain eligible for reporting and credit generation purposes.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.

(a) *Requirements for Attestation Letter.* Each fuel pathway application must include a fuel pathway applicant attestation letter. The attestation letter must attest to the veracity of the information in the application packet and declare that the information submitted accurately represents the long-term, steady state operation of the fuel production process described in the application packet. The attestation letter must conform to the requirements of this subsection. The fuel pathway applicant attestation letter must make the following specific attestations:

(1) No products, co-products, by-products, or wastes undergo additional processing, such as drying, distillation, or clean-up, once they leave the production facility, except as explicitly included in the pathway life cycle analysis and pathway CI.

(2) All data and information supplied is true and accurate in all areas, including, but not limited to the following:

(A) Feedstocks used to produce the fuel;

(B) Fuel and feedstock production technology;

(C) Regions in which feedstocks and finished fuel are produced;

(D) Modes used to transport feedstocks and finished fuel and the transport distances involved;

(E) Types and amounts of thermal and electrical energy consumed in both feedstock and finished fuel production;

(F) Full life cycle carbon intensity, which must be no higher than the carbon intensity specified in the Lookup Table, or Tier 1 or Tier 2 application; and

(G) Fuel production operations.

(3) The signed LCFS fuel pathway applicant attestation letter must:

(A) Be submitted as an electronic copy;

(B) Be on company letterhead;

(C) Be signed by an officer of the applicant with the legal authority to attest to the veracity of the information in the application and to sign on behalf of the applicant;

(D) Be from the applicant and not from an entity representing the applicant (such as a consultant or legal counsel); and

(E) Include the following attestation:

I certify that the current fuel production process used to produce __________ (fuel) at the __________ facility is consistent in all of the following areas with all information submitted to CARB in connection with the pathway request: 1) feedstocks used in fuel production; 2) fuel and feedstock production technology; 3) geographic region in which feedstocks and finished fuel are produced; 4) transportation modes used to transport feedstocks and finished fuel and transport distances; 5) types and amounts of thermal and electrical energy consumed in both feedstock and finished fuel production; and 6) any other applicable fuel pathway standard or operating condition established by CARB. The carbon intensity (CI) of the fuel must be no higher than the CI for the certified FPC.

I understand that the following facility information will be posted on the LCFS ~~web site~~website: Facility Name, Facility Address, Company ID, Facility ID, Fuel Pathway Code(s), CI values, and Fuel Pathway Description(s).

By submitting this form, ____(Fuel Pathway Applicant) accepts responsibility for the information herein provided to CARB. I certify under penalty of perjury under the laws of the State of California that I have personally examined, and am familiar with, the statements and information submitted in this document. I certify that the statements and information submitted to CARB are true, accurate, and complete.

_____________________________ _____________________________ _________

Signature Print Name & Title Date

(b) If the Executive Officer at any time determines that a certified fuel pathway does not meet the requirements of this subarticle or the operational conditions specified in the pathway summary issued by the Executive Officer, the Executive Officer may revoke or modify the certification.

(c) *Designation of Confidential Business Information.* The definition of "confidential business information," for the purposes of this section, is the same as the definition of "trade secret" found in Government Code, section 6254.7. All documents (including spreadsheets and other items not in a standard document format) that are designated to contain confidential business information (CBI) must prominently display the phrase "Contains Confidential Business Information" above the main document title and in a running header. Additionally, a separate, redacted version of such documents must also be submitted. The redacted versions must be approved by the applicant for public posting on ~~LCFS web site. Specific redactions must be replaced with the phrase "Confidential business information has been redacted by the applicant." This phrase~~the LCFS website. The redaction must be displayed clearly wherever CBI has been redacted. If the applicant claims that information it submits is confidential, it must also provide contact information required by California Code of Regulations, title 17, section 91011.

(d) *Public Disclosure of Application Materials and Use of Application Materials in the LCFS Data Management System.*

(1) All information not identified as trade secrets are subject to public disclosure pursuant to California Code of Regulations, title 17, sections 91000 through 91022 and the California Public Records Act (Government Code §§ 6250 et seq.); and

(2) If the application is certified by the Executive Officer, the carbon intensity value(s) and its associated fuel pathway code(s) will be posted publicly on the LCFS ~~web site~~website and incorporated into the LCFS Data Management System for use by fuel reporting entities.

(e) *Submittal Formats.*

(1) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the AFP unless the Executive Officer has approved or requested in writing another format.

(2) The fuel pathway applicant must not convert spreadsheets, including CA-GREET~~3~~4.0 spreadsheets, into other file formats or otherwise take steps to prevent the Executive Officer from examining all values and calculations in those spreadsheets.

(f) *Additional Demonstrations.* Upon request from the Executive Officer, a fuel pathway application must meet the following requirements:

(1) Demonstrate that the fuel that will be produced under the proposed pathway would comply with all applicable ASTM or other generally recognized national consensus standards; and

(2) Demonstrate that the fuel that will be produced under the proposed pathway is not exempt from the LCFS under section 95482(c).

(g) *Specified Source Feedstocks*.

(1) *Pathways Utilizing a Specified Source Feedstock.* In order to be eligible for a reduced CI that reflects the lower emissions or credit associated with the use of a waste, residue, by-product or similar material as feedstock in a fuel pathway, fuel pathway applicants must meet the following requirements.

(A) *Specified source feedstocks include:*

1. Used cooking oil, animal fats, fish oil, yellow grease, distiller's corn oil, distiller's sorghum oil, brown grease, and other fats/oils/greases that are the non-primary products of commercial or industrial processes~~ for food, fuel or other consumer products, which are used as feedstocks in pathways for biodiesel, renewable diesel, alternative jet fuel, and co-processed refinery products~~;

2. Biomethane supplied using book-and-claim accounting pursuant to section 95488.8(i)(2) and is claimed as feedstock in pathways for bio-CNG, bio-LNG, bio-L-CNG, and hydrogen via steam methane reformation;

3. Small-diameter, non-merchantable forestry residues removed for the purpose of forest fire fuel reduction or forest stand improvement and from a treatment where no-clear cutting occurred; Municipal solid waste that is diverted from landfill disposal;

~~3.~~4. Any feedstock whose supplier applies for separate CARB recognition using site-specific CI data; and

~~4.~~5. Other feedstocks designated as specified-source at the time of pathway review and prior to certification.

(B) *Chain-of-custody Evidence.* Fuel pathway applicants using specified source feedstocks must maintain either (1) delivery records that show shipments of feedstock type and quantity directly from the point of origin to the fuel production facility, or (2) information from material balance or energy balance systems that control and record the assignment of input characteristics to output quantities at relevant points along the feedstock supply chain between the point of origin and the fuel production facility. Chain-of-custody evidence is used to demonstrate proper characterization and accurate quantity. Chain-of-custody evidence must be provided to the verifier and to CARB upon request. Joint Applicants may assume responsibility for different portions of the chain-of-custody evidence but each such entity must meet the following requirements to be eligible for a pathway that utilizes a specified source feedstock:

1. Maintain records of the type and quantity of feedstock obtained from each supplier, including Feedstock transaction records, Feedstock Transfer Documents pursuant to section 95488.8(g)(1)(C), weighbridge tickets, bills of lading or other documentation for all incoming and outgoing feedstocks;

2. Maintain records used for material balance and energy balance calculations.

3. Ensure CARB staff and verifier access to audit feedstock suppliers to demonstrate proper accounting of attributes and conformance with certified CI data.

(C) *Feedstock Transfer Documents.* A feedstock transfer document must prominently state the information specified below.

1. Transferor Company name, address and contact information;

2. Recipient Company name, address and contact information;

3. Type and amount of feedstock, including units;

4. Transaction date.

(D) *Requirements for Feedstock Attestation Letter*. Each specified source feedstock supply chain entity must maintain a specified source feedstock supplier attestation letter. Supply chain entities supplying biogas or biomethane used as a feedstock must follow the requirements under section 95488.8(i)(2). The specified source feedstock supply chain entities include points of origin, collectors, aggregators, traders, distributors, and storage facilities that participate in the supply chain from point of origin to the fuel producer for specified source feedstocks. The attestation letter must attest to the veracity of the information supplied, declare that the information accurately represents the specified source feedstock(s), and conform to the requirements of this subsection. The specified source feedstock attestation letter must make the following specific attestations:

1. The specified source feedstocks have not undergone additional processing, such as drying or clean up except as explicitly included in the pathway life cycle analysis and pathway CI.

2. All data and information supplied are true and accurate in all areas, including, but not limited to the following:

    a. Specified source feedstocks meet the applicable definitions under 95481 or as a specified source feedstock approved by the Executive Officer during fuel pathway validation and certification;

    b. Deliveries of the specified source feedstock(s) consist entirely of what is documented on the feedstock transfer documents and are not mixed with any other materials that do not meet the definition of specified source feedstock;

    c. The specified source feedstocks were not intentionally produced, modified, or contaminated to meet the definition;

3. The signed specified source feedstock supplier attestation letter must:

    a. Be maintained by the specified source feedstock supplier, and submitted as an electronic copy upon request by a CARB accredited verifier or verification body or the Executive Officer;

    b. Be on company letterhead;

    c. Be maintained separately for each specified source feedstock;

    d. Be signed by an authorized representative employee of the specified source feedstock supplier;

    e. Include the following attestation:

I certify that the ____________ (specified source feedstock) supplied by ____________ (facility/company) meets all of the following requirements: 1) the specified source feedstock meets the definition under California Code of Regulations, title 17, section 95481, or as a specified source feedstock approved by the Executive Officer; 2) the specified source feedstock has not undergone additional processing, such as drying or clean-up except as explicitly included in the pathway life cycle analysis and pathway CI; 3) deliveries of the specified source feedstock consist entirely of what is documented on the feedstock transfer documents and are not mixed with any other materials that do not meet the definition of the specified source feedstock; and 4) The specified source feedstock was not intentionally modified or contaminated to meet the definition.

By signing this form, ___________ (specified source feedstock supplier) accepts responsibility for the information herein. I certify under penalty of perjury under the laws of the State of California that I have personally examined, and am familiar with, the statements and information in this document. I certify that the statements and information are true, accurate, and complete.

Signature Print Name & Title Date

(h) *Renewable or Low-CI Process Energy.* Unless expressly provided elsewhere in this subarticle, indirect accounting mechanisms for renewable or low-CI process energy, such as the use of renewable energy certificates, cannot be used to reduce CI. In order to qualify as a low-CI process energy source, energy from that source must be directly consumed in the production process as described in (1) and (2) below:

(1) Low-CI electricity must be supplied from generation equipment under the control of the pathway applicant. Such electricity must be able to demonstrate:

(A) Any renewable energy certificates or other environmental attributes associated with the energy are not ~~produced,~~issued credits or ~~are retired and not~~ claimed under any other voluntary or mandatory program with the exception of the federal RFS, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

(B) The generation equipment is directly connected through a dedicated line to a facility such that the generation and the load are both physically located on the customer side of the utility meter. The generation source may be grid-tied, but a dedicated connection must exist between the source and load.

(C) The facility's load is sufficient to match the amount of low-CI electricity claimed using a monthly balancing period.

(2) Biogas or biomethane must be physically supplied directly to the production facility. The applicant must submit the attestation set forth below in section 95488.8(i)(2)(C)2.

(3) Solar steam or heat generation must be physically supplied directly to the production facility, and any environmental attributes associated with the energy are not produced, or are retired and not claimed under any other program with the exception of the federal RFS, and the market-based

compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

(i) *Indirect Accounting for ~~Renewable or~~ Low-CI Electricity ~~and~~, Biomethane, and Low-CI Hydrogen*.

(1) *Book-and-Claim Accounting for ~~Renewable or~~ Low-CI Electricity Supplied as a Transportation Fuel, Direct Air Capture projects, ~~or~~ Used to Produce Hydrogen as a transportation fuel, or Used to Produce a Power-to-Liquid Fuel.* Reporting entities may use indirect accounting mechanisms for low-CI electricity supplied as a transportation fuel ~~or~~, for hydrogen production ~~through electrolysis~~and processing for ~~transportation purposes (including~~ hydrogen ~~that is~~ used ~~in the production of~~as a transportation fuel~~)~~, ~~or~~ for direct air capture projects, or for the production of a power-to-liquid fuel, provided the conditions set forth below are met:

(A) ~~Reporting entities may report low-CI~~ For electricity used as a transportation fuel ~~or as an input to hydrogen production delivered through~~ or as an input to power-to-liquid fuel production, the ~~grid without regard to physical traceability if it meets all requirements of this subarticle. The~~ low-CI electricity must be supplied to the grid within a California Balancing Authority (or local balancing authority for ~~hydrogen~~power-to-liquid fuel produced outside of California) or alternatively, meet the requirements of California Public Utilities Code section 399.16, subdivision (b)(1). Such book-and-claim accounting for low-CI electricity may span only three quarters. If a low-CI electricity quantity (and all associated environmental attributes, including a beneficial CI) is supplied to the grid in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to grid electricity used as a transportation fuel or for ~~hydrogen~~power-to-liquid fuel production no later than the end of the third calendar quarter. After that period is over, any unmatched low-CI electricity quantities expire for the purpose of LCFS reporting.

(B) Low-CI electricity used as a transportation fuel or as an input to power-to-liquid fuel production can be indirectly supplied through a green tariff program (including the Green Tariff Shared Renewables program described in California Public Utilities Code Section 2831-2833) or other contractual electricity supply relationship that meets the following requirements:

1. Electricity is generated by, or supplied under contract to, the pathway applicant for all environmental attributes of the claimed electricity. In order to substantiate low-CI electricity claims, the applicant must make contracts available to the Executive Officer, upon request, to demonstrate that the electricity meets the requirements of this subarticle.

Generation invoices or metering records are required to substantiate the quantity of low-CI electricity produced from the renewable assets. Monthly invoices must be unredacted copies of originals showing electricity sourced (in kWh) and contracted price;

2. All electricity procured by any LSE for the purpose of claiming a lower CI must be in addition to that required for compliance with the California Renewables Portfolio Standard (described in California Public Utilities Code sections 399.11-399.32~~) or, for hydrogen produced outside of California,~~) or, for power-to-liquid fuel produced outside California, in addition to local renewable portfolio requirements;

3. Renewable energy certificates or other environmental attributes associated with the electricity, if any, are ~~retired and~~ not issued credits or claimed under any other voluntary or mandatory program with the exception of the federal RFS, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Retirement of renewable energy credits for the purpose of demonstrating Green Tariff Shared Renewables procurement to the California Public Utilities Commission does not constitute a double claim.

(C) For direct air capture projects or for hydrogen used as a transportation fuel, low-CI electricity must meet the following criteria:

1. The low-CI electricity must be supplied to the grid within the local balancing authority where the electricity is consumed or delivered to that local balancing authority without substitution consistent with the requirements of California Public Utilities Code section 399.16, subdivision (b)(1).

2. The pathway holder or the project operator must be the first contracted entity for procuring the low-CI electricity.

3. Low-CI electricity must be supplied by new or expanded low-CI electricity that begins new or expanded production on or after January 1, 2022, or within three years of the start of the hydrogen production facility or direct air capture project, whichever is later.

4. Such book-and-claim accounting for low-CI electricity may span only one quarter. If a low-CI electricity quantity (and all associated environmental attributes, including a beneficial CI) is supplied to the grid in the first calendar quarter, the quantity claimed for LCFS reporting in the same calendar quarter. After that period is over, any unmatched low-CI electricity quantities expire for the purposes of LCFS reporting.

5. Any renewable energy certificates or other environmental attributes associated with the energy are not issued credits or claimed produced, or are retired and not claimed under any other voluntary or mandatory program with the exception of the federal RFS, incentives under the Infrastructure Investments and Jobs Act or the Inflation Reduction Act, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

(2) *Book-and-Claim Accounting for Pipeline-Injected Biomethane Used as a Transportation Fuel or to Produce Hydrogen.* Indirect accounting may be used for RNG used as a transportation fuel or to produce hydrogen for transportation purposes (including hydrogen that is used in the production of a transportation fuel), provided the conditions set forth below are met:

(A) RNG injected into the common carrier pipeline in North America (and thus comingled with fossil natural gas) can be reported as dispensed as bio-CNG, bio-LNG, or bio-L-CNG, or as an input to hydrogen production, without regards to physical traceability. Entities may report natural gas as RNG within only a three-quarter time span. If a quantity of RNG (and all associated environmental attributes, including a beneficial CI) is pipeline-injected in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to natural gas sold in California as RNG no later than the end of the third calendar quarter. After that period is over, any unmatched RNG quantities expire for the purpose of LCFS reporting.

(B) Biomethane reported under fuel pathways associated with projects that break ground after December 31, 2029, injected into the common carrier pipeline, and claimed indirectly under the LCFS program for use as bio-CNG, bio-LNG, or bio-L-CNG in CNG vehicles or as an input to hydrogen production must demonstrate compliance with the following requirements:

1. Starting January 1, 2041 for bio-CNG, bio-LNG and bio-L-CNG pathways, and January 1, 2046 for biomethane used as an input to hydrogen production, the entity reporting biomethane must demonstrate that the pipeline or pipelines along the delivery path physically flow from the initial injection point toward the fuel dispensing facility at least 50 percent of the time on an annual basis. Entities may report natural gas as RNG within only a three-quarter time span. If a quantity of RNG (and all associated environmental attributes, including a beneficial CI) is pipeline-injected in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to natural gas sold in California as RNG no later than the end of the third calendar quarter. After that period is over, any unmatched RNG quantities expire for the purpose of LCFS reporting.

(C) To substantiate RNG quantities injected into the pipeline for dispensing as bio-CNG, bio-LNG, or bio-L-CNG or as an input to hydrogen production, the pathway application and subsequent Annual Fuel Pathway Reports must include the following documents linking the environmental attributes of RNG (in MMBtu or Therms) with corresponding quantities of natural gas withdrawn: ~~u~~

~~(B)~~1. Unredacted monthly invoices showing the quantities of RNG (in MMBtu) sourced and the contracted price per unit;~~ and the unredacted contract by which the fuel pathway holder obtained the environmental attributes.~~

2. Unredacted contract by which the fuel pathway holder obtained the environmental attributes.

(D) Starting January 1, 2041 for bio-CNG, bio-LNG and bio-L-CNG pathways, and January 1, 2046 for biomethane used as an input to hydrogen production, to substantiate RNG quantities injected into the pipeline for dispensing as bio-CNG, bio-LNG, or bio-L-CNG under fuel pathways associated with projects that break ground after December 31, 2029, the pathway application and subsequent Annual Fuel Pathway Reports must include the documents required by section 95488.8(i)(2)(C) as well as the following documents.

1. Monthly pipeline nomination reports for each pipeline along the delivery path.

~~(C)~~(E) *Attestations Regarding Environmental Attributes*.

1. *Upstream Attestations.* An entity reporting any RNG as a transportation fuel in LRT-CBTS, and a fuel pathway holder using biogas or biomethane as feedstock or process energy, must obtain and keep attestations from each upstream party collectively demonstrating that (a) the entity claiming the environmental attributes has the exclusive right to claim environmental attributes associated with the sale or use of the biogas or biomethane, and (b) no entity has been issued credits based on the environmental attributes ~~have not been used or claimed~~ in any other voluntary or mandatory program ~~or jurisdictions~~ with the exception of the federal RFS, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). ~~The~~The upstream parties must maintain the attestations. The reporting entities' and the upstream parties' attestations must be made available to the Executive Officer or a verifier upon request. The inability to promptly produce the attestations constitutes ground for credit invalidation pursuant to section 95495.

2. *Attestation to CARB.* An officer of any entity reporting biomethane in LRT-CBTS under the provisions of section 95488.8(i)(2), and an officer of any fuel pathway holder claiming use of biogas or biomethane as process energy under the provisions of section 95488.8(h)(2), must annually submit the following attestation to the Executive Officer:

I certify that to the extent that the gas used in the fuel pathway or supplied as transportation fuel is characterized as biomethane, __________ (entity name) owns the exclusive rights to the corresponding environmental attributes.

__________ (entity name) has not sold, transferred, or retired those environmental attributes in any program or jurisdiction other than the federal RFS.

Based on diligent inquiry and review of contracts and attestations from our business partners, I certify under penalty of perjury under the laws of the State of California that no other party has or will sell, transfer, or retire the environmental attributes corresponding to the biomethane for which _______(entity name) claims credit in the LCFS program.

______________________________	______________________________	__________
Signature	Print Name & Title	Date

~~(j) *Measurement Accuracy*.~~

~~(1) *Calibration Requirement.* All measurement devices that log or record data for use in fuel pathway applications must comply with the manufacturer-recommended calibration frequency and precision requirements. If~~

~~manufacturer-recommendations are not provided, the measurement devices must be calibrated every six years.~~

~~(2) *Requests to Postpone Calibration.* For units and processes that operate continuously with infrequent outages, it may not be possible to meet manufacturer-recommended calibration deadlines for measurement devices. In such cases, the owner or operator may submit a written request to the Executive Officer to postpone calibration or inspection until the next scheduled maintenance outage. Such postponements are subject to the procedures of subsections (A) through (B) below and must be documented in the monitoring plan.~~

~~(A) A written request for postponement must be submitted to the Executive Officer not less than 30 days before the required calibration, recalibration or inspection date. The Executive Officer may request additional documentation to validate the operator's claim that the device meets the accuracy requirements of this section. The operator shall provide any additional documentation to CARB within ten (10) business days of a request by CARB.~~

~~(B) The request must include:~~

~~1. The date of the required calibration, recalibration, or inspection;~~

~~2. The date of the last calibration or inspection;~~

~~3. The date of the most recent field accuracy assessment, if applicable;~~

~~4. The results of the most recent field accuracy assessment, if applicable, clearly indicating a pass/fail status;~~

~~5. The proposed date for the next field accuracy assessment, if applicable;~~

~~6. The proposed date for calibration, recalibration, or inspection which must be during the time period of the next scheduled shutdown. If the next shutdown will not occur within three years, this must be noted and a new request must be received every three years until the shutdown occurs and the calibration, recalibration or inspection is completed.~~

~~7. A description of the meter or other device, including at a minimum:~~

~~a. Make,~~

~~b. Model,~~

~~c. Install date,~~

~~d. Location,~~

~~e. Parameter measured by the meter or other device, including the data capture rate,~~

~~f. Description of how data from the meter or other device is used in a fuel pathway,~~

~~g. Calibration or inspection procedure,~~

~~h. Reason for delaying calibration or inspection,~~

~~i. Proposed method to ensure that the precision requirements listed by the manufacturer are upheld,~~

~~j. Name, title, phone number and e-mail of contact person capable of responding to questions regarding the device.~~

~~(k) *Missing Data Provisions*.~~

~~(1) *Meter Record, Accuracy, or Calibration Requirements Not Met.* If a measurement device is not functional, not calibrated within the time period recommended by the manufacturer, or fails a field accuracy assessment, the operator must otherwise demonstrate to the verifier that the reported data are accurate within +/-5 percent.~~

~~(A) If the operator can demonstrate to the verifier that reported data are accurate, the data are acceptable. The entity must then provide a detailed plan describing when the measurement device will be brought into calibration. This plan is subject to approval by the Executive Officer.~~

~~(B) If the operator cannot demonstrate to the verifier that reported data are accurate, the data is not acceptable and missing data provisions apply.~~

~~(2) *Missing Data Provisions.* If missing data exists, the entity must submit for Executive Officer approval an alternate method of reporting the missing data. Alternate methods shall be evaluated on a case-by-case basis.~~

~~(3) *Force Majeure Events.* In the event of a facility shutdown or disruption drastically affecting production attributable to a force majeure event, the fuel pathway applicant or holder must notify the Executive Officer.~~

(3) *Book-and-Claim Accounting for Pipeline-Injected low-CI Hydrogen Used in FCV and Alternative Fuel Production.* Indirect accounting may be used for low-CI hydrogen used in FCVs or to produce alternative fuel for transportation purposes provided the conditions set forth below are met:

(A) Low-CI hydrogen is injected into a dedicated hydrogen pipeline physically connected to California.

(B) The well-to-wheel carbon intensity of low-CI hydrogen does not exceed 55.00 gCO_2e/MJ of gaseous hydrogen or 95.00 gCO_2e/MJ if transported as liquid before pipeline injection. If hydrogen is produced from steam methane reforming of natural gas, book-and-claim accounting of biomethane may be used to meet the carbon intensity thresholds.

(C) Low-CI hydrogen is produced from production facilities that become operational or expand production after December 31, 2022.

(D) Low-CI hydrogen can be reported as dispensed to FCVs or as an input to transportation fuel production, without regards to physical traceability. Entities may report low-CI hydrogen using a monthly balancing period substantiated by contractual documents. After that period is over, any unmatched low-CI hydrogen quantities expire for the purpose of LCFS reporting. Any unmatched quantities of hydrogen must either use a default emission factor for hydrogen provided in the Tier 1 CI Calculator for renewable diesel if hydrogen is used as process input in biofuel production, or use the CI calculated from the Tier 1 CI calculator for hydrogen by considering natural gas as feedstock if hydrogen is used in fuel cell vehicles.

(E) To substantiate low-CI hydrogen quantities injected into the pipeline for dispensing in FCVs or as an input to alternative fuel production, the pathway application and subsequent Annual Fuel Pathway Reports must include the following documents linking the environmental attributes of low-CI hydrogen in kg with corresponding quantities of hydrogen in kg withdrawn from the pipeline: unredacted monthly invoices showing the quantities of low-CI hydrogen (in kg) sourced and the contracted price per kg; and the unredacted contract by which the fuel pathway holder obtained the environmental attributes.

(F) *Attestations Regarding Environmental Attributes.*

1. *Upstream Attestations.* An entity reporting any low-CI hydrogen as a transportation fuel in LRT-CBTS, or a fuel pathway holder using low-CI hydrogen as input to alternative fuel production, must obtain and keep attestations from each upstream party collectively demonstrating that (a) the entity claiming the environmental attributes has the exclusive right to claim environmental attributes associated with the sale or use of the low-CI hydrogen, and (b) no entity has been issued credits based on the environmental attributes in any other voluntary or mandatory program with the exception of the tax credits claimed under the Inflation Reduction Act. The inability to promptly produce attestations constitutes ground for credit invalidation pursuant to section 95495.

2. *Attestation to CARB.* An officer of any entity reporting low-CI hydrogen in LRT-CBTS and an officer of any fuel pathway holder claiming use of low-CI hydrogen as input to alternative fuel production under the provisions of section 95488.8(i)(3), must annually submit the following attestation to the Executive Officer:

I certify that to the extent that the hydrogen used in the fuel pathway or supplied as transportation fuel is characterized as low-CI hydrogen, ___________ (entity name) owns the exclusive rights to the corresponding environmental attributes.

___________ (entity name) has not sold, transferred, or retired those environmental attributes in any program or jurisdiction other than the federal RFS.

Based on diligent inquiry and review of contracts and attestations from our business partners, I certify under penalty of perjury under the laws of the State of California that no other party has or will sell, transfer, or retire the environmental attributes corresponding to the low-CI hydrogen for which ________ (entity name) claims credit in the LCFS program.

Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.9. Special Circumstances for Fuel Pathway Applications.

(a) *Substantiality Requirements*.

(1) The substantiality requirement applies in the two scenarios listed below. The substantiality requirement does not apply when re-applying for a

Provisional pathway with a new operational data period due to a process change, or pathways that qualify for Tier 2 due to the use of low-CI process energy sources, or use of carbon capture, as described in 95488.9(c), or when replacing a certified CI after annual verification using the process described in 95488.10(a)(6).

(A) ~~*Multiple applications*~~*Application(s) for multiple fuel pathways for the same feedstock-fuel combination.* When a fuel pathway applicant applies for two or more pathways ~~based on different inputs~~that are not differentiated by a process change, or applies again for the same feedstock-fuel combination ~~processed within an operational data period~~ at a single fuel production facility, the Executive Officer will consider separate pathways or an updated certification for a previously certified pathway only when the CI of one or more of the proposed pathways meet the substantiality requirement relative to the CI of the reference pathway. The "reference" pathway CI is the composite CI that results when the fuel is modeled using a single pathway that represents the average production of all quantities of the feedstock-fuel combination produced in the operational data period. In the case of an application for a previously certified pathway, the "reference" pathway CI is the verified CI from the most recent annual verification. For the purpose of CI comparison to the reference CI, the applicant must enter the operational data using the same calculator which was used for the most recent annual verification.

~~(B) *Tier 1 Pathways using Innovative Methods.* The Executive Officer will consider a Tier 2 application for a pathway that would otherwise be classified as Tier 1 if the Simplified CI Calculator for that fuel type cannot be used to accurately model the pathway due to process innovations and the proposed pathway meets the substantiality requirement relative to the CI of the reference pathway. The "reference" pathway is the CI of the proposed pathway as calculated by the applicable Simplified CI Calculator. The substantiality requirement does not apply to pathways that qualify for Tier 2 due to the use of low-CI process energy sources, or use of carbon capture, as described in 95488.1(d)(7).~~

(2) The applicant seeking to apply under one of the scenarios described in subsection (1), above, must demonstrate, to the Executive Officer's satisfaction, that the proposed pathway meets the following requirements:

(A) The source-to-tank carbon intensity of the fuel under the proposed pathway meets one of the following two criteria. "Source-to-tank" means all the steps involved in feedstock production and transport, finished fuel production and transport. A source-to-tank CI does not include the carbon intensity associated with the use of the fuel in a vehicle and does not include the LUC modifier.

1. For proposed pathway applications with source-to-tank carbon intensities greater than 20 gCO_2e/MJ (absolute value), that source-to-tank carbon intensity must be at least 5 percent lower than the source-to-tank carbon intensity of the reference pathway; or

2. For proposed pathway applications with source-to-tank carbon intensities of 20 gCO_2e/MJ (absolute value) or less, that source-to-tank carbon intensity must be at least 1 gCO_2e/MJ less than the source-to-tank carbon intensity of the reference pathway.

(b) *Temporary Fuel Pathways*.

(1) Fuel reporting entities may petition the Executive Officer to use a Temporary fuel pathway carbon intensity value for reporting quantities of fuel to generate credits or deficits.

(2) A Temporary pathway petition approved by the Executive Officer will allow the fuel reporting entity to use the pathway for LRT-CBTS reporting purposes for up to two quarters at a time. Reporting will be granted only for the quarter during which the Temporary pathway is approved for use and the subsequent full quarter. The Executive Officer may approve multiple subsequent petitions from the same fuel reporting entity, of up to two quarters each, but each approval will require a new petition.

(3) A petition to use a Temporary pathway must be submitted online in the AFP.

(4) *New Temporary Fuel Pathways.* An entity can apply for the use of a Temporary fuel pathway CI value if it appears in Table 8 in this subarticle or if the Executive Officer approves a new Temporary pathway (for a fuel or feedstock-fuel combination not found in Table 8) and publishes it on the LCFS ~~web site~~website. Any new Temporary pathway proposed by the Executive Officer will be posted for 45 days for public comment prior to certification. The posted information will include the rationale for assigning the CI to that particular Temporary pathway. If these comments require significant revision of the originally published pathway, a revised pathway will be posted for public comment. Upon certification of a new Temporary pathway created by the Executive Officer, the pathway will be available for reporting for the quarter in which it is certified.

Table 8. Temporary Pathways for Fuels with Indeterminate CIs

Fuel	***Feedstock***	***Process Energy***	***CI (gCO_2e/MJ)***
Ethanol	Corn	Grid electricity~~,~~/solar and wind electricity and natural gas~~, and/or renewables~~	90
Ethanol	Grain Sorghum	Grid electricity~~,~~/solar and wind electricity and natural gas~~, and/or renewables~~	95
Ethanol	Any Sugar Feedstock	Bagasse and straw only; no grid electricity	~~55~~60
Ethanol	~~Any Cellulosic Biomass~~ Grain fiber and bagasse	Grid electricity~~,~~/solar and wind electricity~~,~~ and natural gas~~, and/or renewables~~	50
Biomass-based Diesel (HEFA fuels and Biodiesel)	Fats/Oils/Grease Residues	Grid electricity~~,~~/solar and wind electricity and natural gas~~, and/or renewables~~	~~45~~50
Biomass-based Diesel (HEFA fuels and Biodiesel)	Any feedstock derived from plant oils~~,~~ (excluding palm oil and palm derivatives, as a sole feedstock or blended with other feedstocks, and distiller's corn oil)	Grid electricity~~,~~/solar and wind electricity and natural gas~~, and/or renewables~~	~~65~~70
Biomass-based Diesel (HEFA fuels and Biodiesel)	Distiller's Corn Oil	Grid electricity/solar and wind electricity and natural gas	60
Biomass-based Diesel (HEFA fuels and Biodiesel)	Any other feedstock	Grid electricity~~,~~/solar and wind electricity and natural gas~~, and/or renewables~~	Baseline (2010) CI value for ULSD
Renewable Propane	Fats/Oils/Grease Residues	Grid electricity/solar and wind electricity and natural gas	50
Renewable Propane	Any feedstock derived from plant oils (excluding palm oil and palm derivatives, as a sole feedstock or blended with other feedstocks, and distiller's corn oil)	Grid electricity/solar and wind electricity and natural gas	70
Renewable Propane	Distiller's Corn Oil	Grid electricity/solar and wind electricity and natural gas	60
Renewable Propane	Any other feedstock	Grid electricity/solar and wind electricity and natural gas	Baseline (2010) CI value for USLD
Renewable Naphtha and Renewable Gasoline Blendstock	Fats/Oils/Grease Residues	Grid electricity/solar and wind electricity and natural gas	50

Fuel	Feedstock	Process Energy	CI (gCO_2e/MJ)
Renewable Naphtha and Renewable Gasoline Blendstock	Any feedstock derived from plant oils (excluding palm oil and palm derivatives, as a sole feedstock or blended with other feedstocks, and distiller's corn oil)	Grid electricity/solar and wind electricity and natural gas	70
Renewable Naphtha and Renewable Gasoline Blendstock	Distiller's Corn Oil	Grid electricity/solar and wind electricity and natural gas	60
Renewable Naphtha and Renewable Gasoline Blendstock	Any other feedstock	Grid electricity/solar and wind electricity and natural gas	Baseline (2010) CI value for CaRFG
Alternative Jet Fuel	Fats/Oils/Grease Residues	Grid electricity/solar and wind electricity and natural gas	55
Alternative Jet Fuel	Any feedstock derived from plant oils (excluding palm oil and palm derivatives, as a sole feedstock or blended with other feedstocks, and distiller's corn oil)	Grid electricity/solar and wind electricity and natural gas	75
Alternative Jet Fuel	Distiller's Corn Oil	Grid electricity/solar and wind electricity and natural gas	65
Alternative Jet Fuel	Any other feedstock	Grid electricity/solar and wind electricity and natural gas	Baseline (2010) CI value for Fossil Jet Fuel
Fossil LNG	Petroleum Natural Gas	N/A	95
Fossil L-CNG	Petroleum Natural Gas	N/A	100
Biomethane CNG	Landfill gas or Municipal Wastewater Sludge	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	~~70~~65
Biomethane LNG	Landfill gas or Municipal Wastewater Sludge	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	~~85~~80
Biomethane ~~L-CNG~~LCNG	Landfill gas or Municipal Wastewater Sludge	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	~~90~~85
Biomethane CNG	~~Municipal Wastewater sludge,~~ Food Scraps, Urban Landscaping Waste, or Other Organic Waste	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	45

Fuel	*Feedstock*	*Process Energy*	*CI* (gCO_2e/MJ)
Biomethane LNG	~~Municipal Wastewater sludge,~~ Food Scraps, Urban Landscaping Waste, or Other Organic Waste	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	60
Biomethane ~~L-CNG~~LCNG	~~Municipal Wastewater sludge,~~ Food Scraps, Urban Landscaping Waste, or Other Organic Waste	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	65
Biomethane CNG, LNG or L-CNG	Dairy Manure and Swine Manure	Grid electricity/solar and wind electricity, natural gas, and/or parasitic load	-150
Hydrogen (compressed or liquefied)	~~Centralized SMR of fossil LNG~~Natural gas and Biomethane not derived from Dairy and Swine Manure	Grid electricity~~,~~/solar and wind electricity, and natural gas ~~and/~~with gaseous hydrogen transport distance of less than 500 miles or ~~renewables~~liquid hydrogen transport distance of less than 2,000 miles	1~~8~~95
Hydrogen (compressed or liquefied)	Biomethane from Dairy and Swine Manure	Grid electricity/solar and wind electricity and natural gas with gaseous hydrogen transport distance of less than 500 miles or liquid hydrogen transport distance of less than 2,000 miles	40
Hydrogen (compressed or liquefied)	Biomethane from Non-Dairy and Swine Manure Source	Grid electricity/solar and wind electricity and natural gas with gaseous hydrogen transport distance of less than 500 miles or liquid hydrogen transport distance of less than 2,000 miles	175
Hydrogen (compressed or liquefied)	Electrolysis of Water using zero-CI or Negative-CI electricity	Gaseous hydrogen transport distance of less than 500 miles or liquid hydrogen transport distance of less than 2,000 miles	55
Any gasoline substitute feedstock-fuel combination not identified above	Any	Any	Baseline (2010) CI value for CaRFG
Any diesel substitute feedstock-fuel combination not identified above	Any	Any	Baseline (2010) CI value for ULSD

(c) *Provisional Pathways.* As set forth in sections 95488.6(a) and 95488.7(a), LCFS fuel pathways are generally developed based on 24 months of operational data. The Executive Officer may consider Provisional pathway applications from 1) facilities that have been in operation for less than 24 months, or 2) existing facilities that can demonstrate a process change has been implemented, based on at least three months of operational data. Based on timely reports, the fuel reporting entity may generate credits or deficits using a provisionally-certified CI.

(1) *Application process.* Application requirements are the same as those for the applicable pathway classification, specified in sections 95488.6 and 95488.7 including validation of the data submitted in support of the provisional pathway application.

(2) *Verification schedule.* The certified pathway is subject to periodic verification as described in section 95500(b)(2) as applicable for the fuel pathway classification.

~~(3) *Adjusting CI and Credit Balance.* At any time during the 24 months following provisional certification, the Executive Officer may revise as appropriate the provisionally-certified CI. Until the Executive Officer has removed the provisional status pursuant to subsection (4) below, the Executive Officer may adjust the number of credits or reverse any credit in the fuel reporting entity's account using the provisional pathway without a hearing, notwithstanding the requirements of section 95495. At the end of the provisional period, the certified CI will be determined on the basis of 24 months of operational data.~~

~~(A) If the verified operational CI is higher than the provisionally-certified CI, the Executive Officer will replace the certified CI with the verified operational CI in the LRT-CBTS and will make any necessary credit adjustment in the fuel reporting entity's account using the provisional fuel pathway for reporting. Any credits generated using a provisionally-certified CI, across the entire period from original validation to completion of the periodic verification, are subject to adjustment.~~

~~(B) If the verified operational CI is lower than the provisionally-certified CI, the Executive Officer will certify the pathway with the lower CI, adding a conservative margin of safety per section 95488.4(a) if the applicant so desires. The fuel reporting entity will not be eligible for any retroactive credit generation for any quarter for which the reporting deadline has passed, but the revised CI will be valid for future reporting periods.~~

~~(4)~~(3) *Removal of provisional status.* Positive or qualified positive verification statements covering at least 24 months of operational data will result in the removal of the provisional status for the certified pathway.

(d) *Substitute Pathways for Reporting Exports and Other Transaction Types.* If a fuel reporting entity is unable to determine the pathway for reporting a fuel transaction type listed in subsection (1) below, a Substitute pathway corresponding to the fuel type must be used for reporting. Substitute pathways have CI values based on weighted average CIs of that fuel in the prior year, and are provided on the LCFS ~~web site~~website.

(1) The Substitute pathways are only available in the LRT-CBTS for reporting the following transaction types:

(A) Sold without obligation

(B) Purchased without obligation

(C) Export

(D) Loss of inventory

(E) Not used for transportation

(2) When using a Substitute pathway, the fuel reporting entity must use default Company ID and Facility ID values for reporting in the LRT-CBTS. These default values are provided on the LCFS ~~web site~~website.

(e) *Design-based Pathways.* As set forth in sections 95488.6(a) and 95488.7(a), LCFS fuel pathways are generally developed based on 24 months of operational data. However, in order to encourage the development of innovative fuel technologies, an applicant may submit a Design-based pathway application in the AFP for a fully engineered and designed facility with no operational data.

(1) Applications for Design-based pathways must include a detailed life cycle analysis of the anticipated pathway performed using the CA-GREET~~3~~4.0 model, and an LCA report as described in 95488.7(a)(2) detailing facility plans and specifications expected during commercial operation.

(2) The Executive Officer may, fully at his or her discretion, choose to conduct a detailed evaluation of the submitted information and evaluate whether the applicant provided a sufficient level of detail to warrant confidence in energy consumption and other key CI performance metrics. If the Executive Officer chooses to undertake such a review, and the Executive Officer agrees that the pathway warrants publication on the LCFS ~~web site~~website, a Design-based pathway summary will be posted for public comment as detailed in section 95488.7(d)(5) for Tier 2 pathways. Executive Officer approval of Design-based pathways will generally be

contingent upon meeting the requirements detailed in section 95488.7, exclusive of the requirement to obtain a validation statement.

(3) *Ineligibility for credit generation.* Design-based pathways are not eligible to report fuel volumes to the LRT-CBTS or generate credits. After a pathway has been in production for at least three months, in order to be eligible to report and generate credits, the applicant must complete a Provisional pathway application per section 95488.9(c).

(f) *Carbon Intensities that Reflect Avoided Methane Emissions from Dairy and Swine Manure or Organic Waste Diverted from Landfill Disposal*.

(1) A fuel pathway that utilizes biomethane from dairy cattle or swine manure digestion may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary capture of methane, provided that:

(A) A biogas control system, or digester, is used to capture biomethane from manure management on dairy cattle and swine farms that would otherwise be vented to the atmosphere as a result of livestock operations from those farms.

(B) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the capture and destruction of biomethane.

(2) A fuel pathway that utilizes an organic material may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary diversion from decomposition in a landfill and the associated fugitive methane emissions, provided that:

(A) The organic material that is used as a feedstock would otherwise have been disposed of by landfilling, and the diversion is additional to any legal requirement for the diversion of organics from landfill disposal.

(B) Any degradable carbon that is not converted to fuel is subsequently treated in an aerobic system or otherwise is prevented from release as fugitive methane. Upon request, the applicant must demonstrate that emissions are not significant beyond the system boundary of the fuel pathway.

(C) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the avoidance or capture and destruction of biomethane.

(3) Carbon intensities that reflect avoided methane emissions from dairy and swine manure or organic waste projects are subject to the following requirements for credit generation:

(A) *Crediting Periods.* Avoided methane crediting for dairy and swine manure pathways as described in (f)(1) above, and for landfill-diversion pathways as described in (f)(2) above, is limited to three consecutive 10 years crediting periods, counting from the quarter following Executive Officer approval of the application. The pathway holder must formally request each subsequent crediting period for the project through the LRT-CBTS. The Executive Officer may renew crediting periods for fuel pathways certified before January 1, 2030, for up to three consecutive 10-year crediting periods. For pathways for bio-CNG, bio-LNG, and bio-L-CNG used in CNG vehicles associated with projects that break ground after December 31, 2029, the Executive Officer may only approve avoided methane crediting through December 31, 2040. For pathways for biomethane used to produce hydrogen that break ground after December 31, 2029, the Executive Officer may only approve avoided methane crediting through December 31, 2045.

(B) Notwithstanding (A) above, in the event that any law, regulation, or legally binding mandate requiring either greenhouse gas emission reductions from manure methane emissions from livestock and dairy projects or diversion of organic material from landfill disposal, comes into effect in California during a project's crediting period, then the project is only eligible to continue to receive LCFS credits for those greenhouse gas emission reductions for the remainder of the project's current crediting period. The project may not request any subsequent crediting periods.

(C) Notwithstanding (A) above, projects that have generated CARB Compliance Offset Credits under the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800) may apply to receive credits under the LCFS. However, the LCFS crediting period for such projects is aligned with the crediting period for Compliance Offset Credits, and does not reset when the project is certified under the LCFS.

(g) *Sustainability Requirements for Crop-Based and Forestry-Based Feedstocks.*

Crop-based and forestry-based feedstocks must not be sourced on land that was forested after January 1, 2008. A forest is as defined in section 95481 or where they are protected by international or national law or by the relevant competent authority for nature protection purposes.

All crop-based and forestry-based feedstocks used for LCFS fuel pathways must meet the following sustainability requirement:

(1) Maintain continuous third-party sustainability certification under an Executive Officer approved certification system.

(A) All feedstocks at the point-of-origin must be certified by January 1, 2028. Fuel quantities reported under fuel pathways utilizing feedstocks not certified by January 1, 2028 must be assigned the ULSD carbon intensity found in Table 7-1 of the LCFS regulation.

(B) The Executive Officer will review and may approve certification systems based on the following criteria:

1. The certification system has been recognized by an international, national, or state/provincial government for at least 24 months;

2. The certification system must consider environmental, social, and economic criteria;

3. The certification system must be consistent with consensus-based international standards and codes for assuring conformance and certification;

4. The certification system standard-setting process is participatory, and consensus driven:

a. Convenes representative groups of economic, environmental, and social stakeholders in both formal and informal manners; and

b. Creates a representative steering committee, technical working group(s), and advisory group(s);

5. The certification system must have clear, accessible, and transparent processes;

6. The certification system must publish procedures, guidance, certificates and audit report summaries on its website;

7. The certification system must be science based, provide clear targets to reach, and support demonstrable means of evaluation;

8. The certification system must demonstrate that requirements that are additional to the requirements of this subarticle are

vetted via a multi-stakeholder process to mitigate potential stakeholder bias;

9. The certification system must maintain an effective auditor training program to ensure auditor competency;

10. The certification system must maintain an effective oversight program over the participating auditing bodies and auditors to assure consistency and quality of verifications;

    a. The certification system must maintain conflict of interest policies and impartiality provisions to eliminate high potential for conflict of interest;

    b. The certification system must require auditing bodies to maintain professional liability insurance;

    c. The certification system must require auditing bodies to demonstrate that their procedures are consistent with the following international certification systems: ISO 14064-3. Part 3: Specification with guidance for the validation and verification of greenhouse gas assertions, 14065: Greenhouse gases – General principles and requirements for bodies validating and verifying environmental information, 17065: Conformity assessment – Requirements for bodies certifying products, processes and services, and 14066: Competence requirements for greenhouse gas validation teams and verification teams; and

    d. The certification system must require that auditing bodies must assume full responsibility for services performed by subcontractor auditor, and further subcontracting is not allowed;

11. The certification system must include an effective grievance mechanism to ensure that problems are resolved;

12. The certification system must include sanction mechanisms for participating feedstock suppliers and auditing bodies to ensure conformance with its system requirements; and

13. The certification system must demonstrate that policies and mechanisms are in place to monitor and prevent conflicts of interest between members of the system, audited entities, and members of the auditing bodies, consistent with ISO 17065: Conformity assessment -- Requirements for bodies certifying products, processes and services. The certification

system must have oversight mechanisms to assure knowledgeable and rigorous compliance of audit providers.

(C) Certification systems must be approved by the Executive Officer prior to the reporting deadline for the AFPR or QFTR the feedstock is being reported under.

(D) To apply for Executive Officer approval, the applicant must submit the following information to the Executive Officer:

1. General information on the certification system, including:

a. The name, address, telephone number, and e-mail address of the certification system;

b. A description of all services the certification system performs or intends to perform; and

c. A list of auditing bodies that are currently approved by the certification systems; and

2. A demonstration that the certification system has met the selection criteria specified in section 95488.9(g)(1)(B) and that the listed auditing bodies have met the requirements in 95488.9(g)(1)(B)(10).

(E) Certification system documents must be submitted to the Executive Officer at least 90 days prior to the reporting deadline for approval.

1. The submittal must include all documentation necessary for the Executive Officer to determine that the above identified criteria have been met.

2. The certification system documents may be submitted for Executive Officer review by a representative of the certification system, a feedstock supplier, a fuel producer, or any other participant in the LCFS.

3. The Executive Officer may request additional information from the submitter, and the submitter must provide the requested information within 14 days.

4. If a certification system is denied, the submitter may appeal to the Executive Officer within 30 days and provide any additional information that may be helpful in making a determination of acceptability.

5. The Executive Officer has 30 days from the date of appeal submittal to make a final determination.

(F) Approved certification systems will be published on the CARB LCFS website.

(G) Once a certification system is approved it is eligible for use by all relevant feedstock suppliers.

(H) Certification systems must be resubmitted for approval every three years to assure continuing adherence to the original approval standards.

(I) The Executive Officer may remove or suspend an approved certification system standard that no longer meets the requirements of section 95488.9(g)(1)(B).

(J) After the removal or suspension of an approved certification system standard, any feedstock relying on that standard must become certified under an approved standard within one year from the date of removal or suspension.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95488.10. Maintaining Fuel Pathways.

(a) *CI Data Reporting Requirement and Deadline.* Beginning in 2021, each fuel pathway holder must submit an annual Fuel Pathway Report to the AFP no later than March 31 of each calendar year.

(1) The annual Fuel Pathway Report must include the certified version of the ~~Simplified~~Tier 1 CI Calculator or the CA-GREET~~3~~4.0 model, if required in the initial certification, updated to include the most recent two calendar years of operational data. If less than 24 months of operational data is reported in an Annual Fuel Pathway Report, the operational data period must include the reported months established during initial pathway certification.

(2) The annual Fuel Pathway Report for Lookup Table pathways listed in 95488.1(b)(2), in lieu of the CI calculator, must include invoices or metering records substantiating the quantity of renewable or low-CI inputs procured from a qualifying source.

(3) Entities specified in section 95488.8(i)(2)(C) must provide the annual attestation regarding environmental attributes required by that provision.

(4) Any fuel pathway holder, including a joint applicant, who is not subject to site visits by a third~~-~~-party verifier, whose pathway involves the use of renewable or low-CI process energy, must submit invoices for that energy to the AFP. Additionally, for any electricity that is used to reduce carbon intensity of electricity used as a transportation fuel or hydrogen production via electrolysis, the pathway holder must upload records demonstrating that any renewable energy certificates generated were retired in WREGIS for the purpose of LCFS credit generation.

(5) The annual Fuel Pathway Report must include any temporally-variable information requested by the Executive Officer to be included in the initial application as supplementary information, or required data or documentation listed in the pathway summary operating conditions, must continue to be submitted annually as part of the annual Fuel Pathway Report.

~~(6) If the verified operational CI as calculated from production data covering the 24 months of operations is found to be lower than the certified CI, and a positive verification statement is issued for this period, the following options are available:~~

(6) Fuel pathway holders must submit 2024 annual Fuel Pathway Reports following the transition to CA-GREET4.0 procedure described in section 95488(c)(1). Upon receiving a positive or qualified positive verification statement for verification of a 2025 Annual Fuel Pathway Report and subsequent reporting years, the Executive Officer will replace the certified CI with the verified operational CI if this replacement is requested by the fuel pathway holder. The Executive Officer will add a conservative margin of safety to the verified operational CI per section 95488.4(a) upon request from the pathway holder.

(A) The fuel pathway holder may elect to keep the original certified CI.

(B) The fuel pathway holder may request to replace the certified CI with the verified operational CI based on the most recent 24 months of operational data, adding a conservative margin of safety per section 95488.4(a) if the applicant so desires. Fuel pathway holders requesting to replace the certified CI must submit an attestation that the new CI can be maintained through the next reporting period, and acknowledging that exceeding the newly certified CI in subsequent verifications will constitute non-compliance with the requirements of this subarticle.

(7) If the verified operational CI is found to be greater than the certified ~~CI,~~(including provisionally certified) CI:

(A) The Executive Officer will invalidate excess credits generated resulting from the CI exceedance for the applicable compliance year in the LRT-CBTS account of the associated fuel reporting entities.

(B) The fuel pathway holder is subject to the deficit obligation for a verified CI exceedance pursuant to 95486.1(g).

(C) Fuel pathway holders who demonstrate that the verified operational CI exceedances are solely due to calculator updates are exempt from the 95486.1(g) deficit obligation for the 2025 and 2026 compliance years. To make this demonstration, fuel pathway holders must submit both CA-GREET3.0 and CA-GREET4.0 modeling tools populated with the operational data for the same reporting period for annual verification in the AFP.

~~(7)~~(D) Unless the fuel pathway holder satisfies the 95486.1(g) deficit obligation or the exemption to that deficit obligation requirement specified in 95488.10(a)(7)(C) applies, the fuel pathway holder of a pathway with 24 months of operational data is out of compliance ~~with this subarticle~~per section 95488.4(a) and subject to investigation by the Executive Officer and possible enforcement action.

(b) *Credit True Up after Annual Verification.* Beginning with the 2025 annual Fuel Pathway Report data reporting year, the Executive Officer may perform credit true up for a fuel pathway that has a lower verified operational CI upon receiving a positive or qualified positive verification statement for the associated annual fuel pathway report and quarterly fuel transactions reports, notwithstanding the prohibition on retroactive credit generation in section 95486(a)(2). To implement this true up, the Executive Officer will calculate an equivalent number of credits representing the difference between the reported CI and the verified operational CI from annual Fuel Pathway Reports for each fuel pathway code reported with non-liquid transaction types and with the following liquid fuel transaction types "Production in California," "Production for Import," and "Import" during a compliance year, and place those credits in the account of each appropriate fuel reporting entity after August 31 for the prior compliance year. The credits will be calculated according to the following equation:

$$Credits^{FPC}_{CI\ difference}\ (MT)$$
$$= \left(Credits^{FPC}_{verified\ opertional\ CI}\ (MT) - Credits^{FPC}_{reported\ CI}\ (MT)\right)$$

If $Credits^{FPC}_{CI\ difference} > 0$

where:

$Credits^{FPC}_{CI\ difference}$ is the number of credits representing the difference between the reported CI and verified operational CI for each fuel pathway code;

$Credits^{FPC}_{verified\ operational\ CI}$ is the number of credits calculated using $CI^{XD}_{verified\ operational}$ instead of $CI^{XD}_{reported}$ in the equation in section 95486.1(a)(1). $CI^{XD}_{verified\ operational}$ is determined by the Executive Officer on the basis of the annual Fuel Pathway Report submitted pursuant to section 95488.10 for each fuel pathway code; and

$Credits^{FPC}_{reported\ CI}$ is the number of credits calculated using equation in section 95486.1(a)(1) for each fuel pathway code;

~~(b)~~(c) *Monitoring Plan for Entities Required to Obtain Validation or Verification Services under the LCFS*. Each entity responsible for obtaining validation or verification under this subarticle must complete and retain for review by a verifier, or the Executive Officer, a written Monitoring Plan. Specific requirements for Monitoring Plans are detailed in section 95491.1(c).

~~(c)~~(d) *Verification Requirement and Deadline.* Each fuel pathway holder, who is not exempt from obtaining verification in section 95500, must ensure that a positive or qualified positive verification statement covering the annual Fuel Pathway Report is received by the Executive Officer from the verification body pursuant to the schedule in 95500 in order to maintain a valid fuel pathway code for use in reporting fuel transactions. An adverse fuel pathway verification statement would result in investigation by the Executive Officer. It is the responsibility of the fuel pathway holder to ensure this deadline is met.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95489. Provisions for Petroleum-Based Fuels.

(a) *Deficit Calculation for CARBOB ~~or~~, Diesel Fuel~~.~~, or Fossil Jet Fuel.* A fuel reporting entity for CARBOB ~~or~~, diesel fuel, or fossil jet fuel must calculate separately the base deficit and incremental deficit for each fuel or blendstock derived from petroleum feedstock as specified in this provision.

Base Deficit Calculation

$$Deficits^{XD}_{Base}(MT) = (CI^{XD}_{Standard} - CI^{XD}_{BaselineAve}) \times E^{XD} \times C$$

Incremental Deficit Calculation to Mitigate Increases in the Carbon Intensity of Crude Oil

If $CI_{20XXCrudeAve} > CI_{BaselineCrudeAve} + 0.10$ *then:*

$$Deficits^{XD}_{Incremental20XX} = (CI_{BaselineCrudeAve} - CI_{20XXCrudeAve}) \times E^{XD} \times C$$

If $CI_{20XXCrudeAve} \leq CI_{BaselineCrudeAve} + 0.10$ *then:*

$$Deficits^{XD}_{Incremental20XX} = 0$$

where:

$Deficits^{XD}_{Base}(MT)$ and $Deficits^{XD}_{Incremental20XX}$ mean the amount of LCFS deficits incurred (a negative value), in metric tons, by the volume of CARBOB (XD = "CARBOB") and diesel fuel (XD = "diesel") that is derived from petroleum feedstock and is either produced in or imported into California during a specific calendar year, and by the volume of fossil jet fuel (XD = "fossil jet fuel") that is either produced or imported into California during a specific calendar year, starting in 2028;

$CI^{XD}_{Standard}$ has the same meaning as specified in section 95486.1(a);

$CI^{XD}_{BaselineAve}$ is the average carbon intensity value of CARBOB ~~or~~, diesel, or fossil jet fuel in gCO2e/MJ, that is derived from petroleum feedstock and is either produced in or imported into California during the baseline calendar year, 2010. For purposes of this provision, $CI^{XD}_{BaselineAve}$ for CARBOB (XD = "CARBOB~~")~~ ~~and~~"), diesel fuel (XD = "diesel"), and fossil jet fuel (XD = "fossil jet fuel") are the Baseline Average carbon intensity values for CARBOB ~~and~~, diesel (ULSD~~)~~), and fossil jet fuel set forth in Table 7-1. The Baseline Average carbon intensity values for CARBOB ~~and~~, diesel (ULSD~~)~~), and fossil jet fuel are calculated using data for crude oil supplied to California refineries during the baseline calendar year, 2010.

$CI_{BaselineCrudeAve}$ is the California Baseline Crude Average carbon intensity value, in gCO2e/MJ, attributed to the production and transport of the crude oil supplied as petroleum feedstock to California refineries during the baseline calendar year, 2010. For comparison to $CI_{20\cancel{18}23CrudeAve}$, the baseline is:

$$CI_{BaselineCrudeAve} = \cancel{\frac{[11.98 \times V_{2016} + 11.98 \times V_{2017} + 11.78 \times V_{2018}]}{[V_{2016} + V_{2017} + V_{2018}]}} \frac{[11.98 \times V_{2021} + 11.98 \times V_{2022} + 11.78 \times V_{2023}]}{[V_{2021} + V_{2022} + V_{2023}]}$$

For comparison to $CI_{2019CrudeAve}$, the baseline is:

$$CI_{BaselineCrudeAve} = \cancel{\frac{[11.98 \times V_{2017} + 11.78 \times V_{2018} + 11.78 \times V_{2019}]}{[V_{2017} + V_{2018} + V_{2019}]}} \frac{[11.98 \times V_{2022} + 11.78 \times V_{2023} + 11.78 \times V_{2024}]}{[V_{2022} + V_{2023} + V_{2024}]}$$

For comparison to $\cancel{CI_{2020CrudeAve}}CI_{2025CrudeAve}$ and subsequent years, the baseline is

$$CI_{BaselineCrudeAve} = 11.78$$

$CI_{20XXCrudeAve}$ is the Three-year California Crude Average carbon intensity value, in gCO_2e/MJ, attributed to the production and transport of the crude oil supplied as petroleum feedstock to California refineries during the most recent three calendar years. For example, the Three-year California Crude Average carbon intensity value for 20~~18~~23 is:

$$CI_{2018CrudeAve} = \cancel{\frac{[CI_{2016} \times V_{2016} + CI_{2017} \times V_{2017} + CI_{2018} \times V_{2018}]}{[V_{2016} + V_{2017} + V_{2018}]}} \frac{[CI_{2021} \times V_{2021} + CI_{2022} \times V_{2022} + CI_{2023} \times V_{2023}]}{[V_{2021} + V_{2022} + V_{2023}]}$$

V_{20XX} is the total volume of crude supplied to California refineries during the specified year 20XX.

CI_{20XX} is the Annual Crude Average carbon intensity value, calculated annually as described in section 95489(b). The Annual Crude Average carbon intensity value for 2021~~6~~ and 20~~17~~22 are specified in Table 9.

E^{XD} is the amount of fuel energy, in MJ, ~~from CARBOB (XD = "CARBOB") or diesel (XD = "diesel"),~~ determined from the energy density conversion factors in Table 4~~,~~. For CARBOB (XD = "CARBOB") or diesel (XD = "diesel"), E^{XD} is either produced in California or imported into California during a specific calendar year and sold, supplied, or offered for sale in California. For fossil jet fuel (XD = "fossil jet fuel"), E^{XD} is either produced in California or imported into California during a specific calendar year starting in 2028 and sold, supplied, or offered for sale in California.

$$C = 1.0 \times 10^{-6} \frac{MT}{gCO_2e}$$

(b) *Addition of Incremental Deficits that Result from Increases in the Carbon Intensity of Crude Oil to a Fuel Reporting Entity's Compliance Obligation*.

(1) Incremental deficits for CARBOB ~~or~~, diesel fuel, or fossil jet fuel that result from increases in the carbon intensity of crude oil will be calculated and added to each affected fuel reporting entity's compliance obligation for the compliance period in which the $Deficits^{XD}_{Incremental20XX}$ become effective, which will be the year following the year in which the $CI_{20XXCrudeAve}$ was established.

(2) Incremental deficits for CARBOB ~~or~~, diesel fuel, or fossil jet fuel for each fuel reporting entity will be based upon the amount of CARBOB ~~and~~, diesel fuel, and fossil jet fuel supplied by the fuel reporting entity in each compliance period for which the $Deficits^{XD}_{Incremental20XX}$ are effective.

(3) *Process for Calculating the Annual Crude Average Carbon Intensity Value*.

(A) An Annual Crude Average carbon intensity value will be calculated for each calendar year using a volume-weighted average of crude carbon intensity values. The volume for each imported crude will be the total volume of that crude reported by all fuel reporting entities in the Annual Compliance Reports for the calendar year. Volume contributions for California State fields will be based on oil production data from the California Department of Conservation and volume contributions for California Federal Offshore fields will be based on oil production data from the Bureau of Safety and Environmental Enforcement. Field production volumes for California-produced crude will be reduced, if necessary, to account for crude exports. Crude carbon intensity values are those listed in Table 9. For crude names not listed, the default carbon intensity value from Table 9 will be used until the crude name and carbon intensity value is added to Table 9 as described in section 95489(b)(3).

(B) ~~Within 15 days of receiving the Annual Compliance~~After receiving positive or qualified positive verification statements required by section 95500 for all annual MCON reports, the Executive Officer shall post the Annual Crude Average carbon intensity calculation at the LCFS ~~web site~~website for public comment. Written comments shall be accepted for ~~15~~14 days following the date on which the analysis was posted. Only comments related to potential factual or methodological errors in the posted Annual Crude Average carbon intensity value may be considered. The Executive Officer shall evaluate the comments received and, if the Executive Officer deems it necessary, may request in writing additional information or clarification from the commenters. Commenters shall be provided ~~10~~14 days to respond to these requests. ~~The~~After any comments necessary to be addressed have been addressed, the Executive Officer shall post the final Annual Crude Average carbon intensity value at the LCFS ~~web site within 15 days of receiving positive or qualified positive MCON verification reports per section 95500.~~website. An adverse verification statement would result in Executive Officer investigation and may result in delay of finalizing and posting the Annual Crude Average carbon intensity value.

(C) Revisions to the OPGEE model, addition of crudes to Table 9, and updates to all carbon intensity values listed in Table 9 will be considered ~~on a three-year cycle~~ through proposed amendments of the Low Carbon Fuel Standard regulation.

Table 9. Carbon Intensity Lookup Table for Crude Oil Production and Transport.

Country of Origin	***Crude Identifier***	***Carbon Intensity (gCO_2e/MJ)***
Baseline Crude Average*	California Baseline Crude Average applicable to crudes supplied during 20~~18~~23 and subsequent years	~~11.78~~12.61

* Based on production and transport of the crude oil supplied to the indicated California refinery(ies) during the baseline calendar year, 2010.

(c) *Credits for Producing and Transporting Crudes using Innovative Methods.* Credits may be generated for crude oil that has been produced or transported using innovative methods and delivered to California refineries for processing.

(1) *General Requirements*.

(A) For the purpose of this section, an innovative method means crude production or transport using one or more of the following technologies:

1. Solar steam generation (generated steam of 45 percent quality or greater). Steam must be used onsite at the crude oil production or transport facilities.

2. Carbon capture and sequestration (CCS). Carbon capture must take place onsite at the crude oil production or transport facilities from existing anthropogenic sources of CO_2.

3. Solar or wind electricity generation. To qualify for the credit, electricity must be produced and consumed onsite or be provided directly to the crude oil production or transport facilities from a third-party generator and not through a utility owned transmission or distribution network. Energy storage may be used to increase the quantity of electricity supplied to crude oil production or transport facilities from intermittent solar and wind electricity generation sources.

4. Solar heat generation including, but not limited to, boiler water preheating and solar steam generation with a steam quality of less than 45 percent. Heat must be used onsite at the crude oil production or transport facilities.

5. Renewable natural gas (RNG) or biogas energy. RNG or biogas must be physically supplied directly to the crude oil production or transport facilities.

(B) The innovative method must become operational no earlier than 2010 for solar steam and CCS projects or January 1, 2015, for any other innovative method above. Any project must be approved for use by the Executive Officer before generating credit under the LCFS regulation. Projects that utilize carbon capture and sequestration are subject to the provisions of section 95490.

No credits may be generated for any quarter preceding the quarter in which the application is approved.

(C) The project operator must initiate review of the opt-in project using the innovative method through a written application to the Executive Officer. If the innovative method involves steam, heat, RNG, biogas, or electricity produced by a third party and delivered to the crude oil producer or transporter, both the crude producer or transporter and the third party must apply and will be considered joint applicant project operator for approval of the innovative method. If more than one crude producer or transporter receives steam, heat, RNG, biogas, or electricity from a single third-party facility, each crude producer or transporter must submit an independent application with the third party as a joint applicant on each submittal. If the innovative method involves delivery of carbon captured by the crude oil producer or transporter to a third party to store the carbon, both the crude producer or transporter and the third party must apply and will be considered joint applicants for approval of the innovative method.

(D) A crude oil producer or transporter or designated third party join application must register under section 95483.1 as an opt-in project operator to receive credits for an approved innovative method. The crude oil producer or transporter, through a written agreement, may elect to transfer the right to opt in for credit generation to the joint applicant. If neither the crude oil producer or transporter nor the joint applicant using an approved innovative method registers as an opt-in project operator, credits generated by the producer's or transporter's use of the innovative method may be claimed by California refinery(ies) that purchase the crude produced or transported using the innovative method if CARB receives all information it needs to ensure compliance with limitations and reporting requirements applied to the method.

~~(E)~~ The innovative method must achieve ~~one of the following threshold criteria:~~

~~1. A carbon intensity reduction from the comparison baseline of at least 0.10~~ ~~gCO_2e/MJ~~~~, or~~

2. ~~An~~an emissions reduction of at least ~~5~~1,000 metric tons CO_2e per year.

(E) If the innovative method involves more than one crude producer or transporter using steam, heat, RNG, biogas, or electricity produced at a single third-party facility, the threshold criteria listed above may apply to the aggregated project total.

(F) Credits for producing crude oil with innovative methods must be calculated as specified below:

For crude oil produced using solar steam generation:

$$Credits_{Innov}(MT) = Avoided\ emissions \times \frac{V_{steam} \times f_{solar}}{V_{crudeproduced}} \times V_{Innov} \times C$$

Where avoided emissions, as calculated using the OPGEE model assuming displacement of steam produced using a natural gas fired once through steam generator, are correlated with the steam quality as tabulated below:

Steam quality	***Avoided emissions (gCO_2e/bbl solar steam)***
95% and above	~~34,875~~33,982
85% to <95%	~~30,443~~31,334
75% to <85%	~~28,188~~29,001
65% to <75%	~~25,932~~26,669
55% to <65%	~~23,677~~24,337
45% to <55%	~~21,421~~22,004

For crude oil produced or transported using solar or wind based electricity:

$$Credits_{Innov}(MT) = \cancel{511}314 \times \frac{E_{electricity} \times f_{renew}}{V_{crudeproduced}} \times V_{Innov} \times C$$

For crude oil produced or transported using any other innovative method listed in section 95489(c)(1)(A):

$$Credits_{Innov}(MT) = \Delta CI_{Innov} \times E_{Innov} \times V_{Innov} \times C$$

where:

$Credits_{Innov}(MT)$ means the amount of LCFS credits generated (a positive value), in metric tons, by the volume of a crude oil produced or transported using the innovative method and delivered to California refineries for processing;

V_{steam} means the overall volume, in barrels cold water equivalent, of steam injected;

f_{solar} means the fraction of injected steam that is produced using solar;

$V_{crudeproduced}$ means the volume, in barrels, of crude oil produced or transported using the innovative method;

V_{Innov} means the volume, in barrels, of crude oil produced or transported using the innovative method and delivered to California refineries for processing. If the crude produced or transported using the innovative method and delivered to California refineries is part of a blend, then V_{Innov} is the volume of blend delivered to California refineries times the volume fraction of the crude within the blend that was produced or transported using the innovative method.

$$C = 1.0 \times 10^{-6} \frac{MT}{gCO_2e}$$

$E_{electricity}$ means the overall electricity consumption to produce or transport the crude, in kW-hr;

f_{renew} means the fraction of consumed electricity that is produced using qualifying solar or wind power;

ΔCI_{Innov} means the reduction in carbon intensity (a positive value), in gCO_2e/MJ_{crude}, associated with crude oil production or transport with the innovative method as compared to crude oil production or transport by a baseline process without the method (hereafter referred to as the comparison baseline method); and

E_{Innov} means the energy density (lower heating value), in MJ/barrel, for the crude oil produced or transported with the innovative method.

(G) Renewable or low-CI energy sources listed in (A) that are used to generate LCFS credit for innovative crude may not also claim renewable energy certificates or other environmental attributes recognized or credited by any other jurisdiction or regulatory program, other than the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Any renewable energy certificates or other environmental attributes associated with the energy must be retired for the purpose of LCFS credit generation.

(2) *Application and Data Submittal.* Unless otherwise noted, an application for an innovative method shall comply with the requirements below:

(A) An applicant that submits any information or documentation in support of a proposed innovative method must include with the application a written statement clearly showing that the applicant understands and agrees to the following:

1. That all information in the application not identified as confidential business information is subject to public disclosure pursuant to California Code of Regulations, title 17, sections 91000 through 91022 and the California Public Records Act (Government Code §§ 6250 et seq.), and that information claimed by the applicant to be confidential might later be disclosed under section 91022 if the state board determines the information is subject to disclosure.

2. That the crude oil producer or transporter or third-party joint applicant must register under section 95483.1 as an opt-in project operator to receive LCFS credit for an innovative method, and that if the crude oil producer or transporter or third-party joint applicant does not register as an opt-in project operator, credits from an approved innovative method may be claimed by California refinery(ies) that purchase crude produced from the innovative method.

(B) An application must contain the following summary material:

1. A complete description of the innovative method and how emissions are reduced;

2. An engineering drawing(s) or process flow diagram(s) that illustrates the innovative method and clearly identifies the system boundaries, relevant process equipment, mass flows, and energy flows necessary to calculate the innovative method credits;

3. A map including global positioning system coordinates for the facilities described in section 95489(c)(2)(B)2.; and

4. A preliminary estimate of the potential innovative method credit, calculated as required in section 95489(c)(1)(F), including descriptions and copies of production and operational data or other technical documentation utilized in support of the calculation.

(C) An application, except for solar-generated steam for crude oil production (45 percent steam quality or greater), wind-based electricity, or solar-based electricity, shall include a detailed description of the innovative method and its comparison baseline method. The description of innovative and comparison baseline methods can be limited to those portions of the crude production or transport process affected by the innovative method. The description of the innovative method and its comparison baseline method must include each of the following, to the extent each is applicable to the innovative method:

1. Schematic flow charts that identify the system boundaries used for the purposes of performing the life cycle analyses on the proposed innovative method and the comparison baseline method. Each piece of equipment or stream appearing on the process flow diagrams shall be clearly identified and shall include data on its energy and materials balance. The system boundary shall be clearly shown in the schematic.

2. A description of all material and energy inputs entering the system boundaries, including their points of origination, modes of transportation, transportation distances, means of storage, and all processing to which material inputs are subject.

3. A description of all material and energy products, co-products, byproducts, and waste products leaving the system boundaries, including their respective destinations, transportation modes, and transportation distances.

4. A description of all facilities within the system boundaries involved in the production or transport of the crude oil and other byproducts, co-products, and waste products.

5. A description of all combustion and electricity-powered equipment within the system boundaries, including their respective capacities, sizes, or rated power, fuel utilization type, fuel shares, energy efficiency (lower heating value basis), and proposed use.

6. A description of the thermal and electrical energy production that occurs within the system boundaries, including the respective capacities, sizes, or rated power, fuel utilization type, fuel shares, energy efficiency (lower heating value basis), and proposed use.

7. A description of all sources of flared, vented, and fugitive emissions within the system boundaries, including the

compositions of the flared, vented, and fugitive emission streams leaving the system boundaries.

(D) An application, except for solar-generated steam for crude oil production (45 percent steam quality or greater), wind-based electricity, or solar-based electricity shall include descriptions of the life cycle assessments (LCAs) performed on the proposed innovative method and its comparison baseline method using the CARB OPGEE model or an alternative model or LCA methodology approved by the Executive Officer. Electronic copies of the models and calculations shall be provided with the application. The descriptions of the life cycle assessment results must include each of the following:

1. Detailed information on the energy consumed, the greenhouse gas emissions generated for the innovative method and the comparison baseline method;

2. Documentation of all non-default model input values used in the emissions calculation process. If values for any significant production parameters are unknown, the application shall so state and model default values shall be used for these parameters in the analysis;

3. Detailed description of all supporting calculations that were performed outside of the model; and

4. Documentation of all modifications other than those covered by subsection 2., above, made to the model. This discussion shall include sufficient specific detail to enable the Executive Officer to replicate all such modifications and, in combination with the inputs and supporting calculations identified in subsections 2. and 3., above, replicate the carbon intensity results reported in the application.

(E) An application shall include a list of references covering all information sources used in the preparation of the life cycle analysis and calculation of innovative method credit. The reference list must meet the requirements of section 95488.7(a)(2)(D).

(F) An application shall include a signed transmittal letter from the applicant attesting to the veracity of the information in the application packet and declaring that the information submitted accurately represents the actual and/or intended long-term, steady-state operation of the innovative method described in the application packet. The transmittal letter must meet the requirements of section 95488.8(a)(3)(A) through (D).

(G) CBI must be designated and a redacted version of any submitted documents designated to include CBI must be provided pursuant to the requirements described in section 95488.8(c).

(H) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the ~~AFP~~LRT-CBTS unless the Executive Officer has approved or requested another format.

(3) *Application Approval Process.* The application must be approved by the Executive Officer before the crude oil producer or transporter, joint applicant, or purchasing refinery may generate credit for the innovative method.

(A) ~~Within 30 calendar days of~~Following receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer shall advise the applicant in writing either that:

1. The application is complete, or

2. The application is incomplete, in which case the Executive Officer will identify which requirements of section 95489(c) have not been met.

a. The applicant may submit additional information to correct deficiencies identified by the Executive Officer.

b. If the applicant is unable to achieve a complete application within 180 days of the Executive Officer's receipt of the original application, the application will be denied on that basis, and the applicant will be informed in writing.

(B) ~~After accepting an application as complete, the Executive Officer will post the application at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm.~~ If the Executive Officer deems the application ready for validation, the applicant will be notified accordingly and provided with a list of eligibility requirements and comparison baseline inputs required for validation. The applicant must seek the services of an Executive Officer accredited verification body for validation as specified in section 95500 before the application can be accessed by the verification body. A positive or qualified positive validation statement must be received by the Executive Officer from the verification body in order for CARB's evaluation and certification of the project application to proceed. In cases where a single applicant or a joint applicant does not complete validation, the application will be denied without prejudice. In cases where an applicant cannot complete validation within six months of the verification body receiving the application from CARB, or receives an adverse validation statement, the application will be denied without prejudice.

~~(B)~~(C) After receiving a positive or qualified positive validation statement, the Executive Officer will post the application at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm. Public comments will be accepted for ~~10~~14 days following the date on which the application was posted. Only comments related to potential factual or methodological errors may be considered. The Executive Officer will forward to the applicant all comments identifying potential factual or methodological errors. Within 30 days, the applicant shall either submit revisions to its application to the Executive Officer, or submit a detailed written response to the Executive Officer explaining why no revisions are necessary.

~~(C)~~(D) The Executive Officer shall not approve an application if the Executive Officer determines, based upon the information submitted in the application and any other available information, that:

1. The proposed crude production or transport method is not an innovative method, as that term is defined in section 95489(c)(1).

2. Based upon the application information submitted pursuant to this section, the applicant's greenhouse gas emissions calculations cannot be replicated using the CARB OPGEE model or alternative model or LCA methodology approved by the Executive Officer.

~~(D)~~(E) As part of any action approving an application, the Executive Officer may prescribe conditions of the approval that contain special limitations, recordkeeping and reporting requirements, and operational conditions that the Executive Officer determines should apply to the innovative method. If the Executive Officer determines the application will not be approved, and the applicant will be notified in writing and the basis for the disapproval shall be identified.

(4) *Recordkeeping and Reporting.* Each applicant that receives approval for an innovative method must maintain records identifying each facility at which it produces crude oil for sale in California under the approved innovative method. For each such facility, the ~~applicant~~regulated entity must report quarterly or annually (through a Project Report~~) and maintain records~~); a regulated entity electing to report annually is required to submit its annual Project Report to CARB for the previous compliance year by

April 30 of each year. Records of each such facility must be maintained for at least ten years showing:

(A) The volume (barrels) of crude oil produced or transported using the approved innovative method and the crude name(s) under which it is marketed.

(B) If the crude oil produced or transported with an approved innovative method is marketed as part of a crude blend that is not wholly refined in California, the name of the blend and the volume fraction that the crude produced with the innovative method contributes to the blend.

(C) For crude oil imported into California, documentation showing that the innovative crude was supplied to one or more California refinery and the volume (barrels) of innovative crude supplied to each California refinery. For crude oil produced in California, documentation showing the innovative crude was supplied to one or more California refinery, the total volume (barrels) of innovative crude supplied to California refineries, and the total volume (barrels) of innovative crude exported from California.

(D) For solar or wind electricity projects, the following additional recordkeeping and reporting will be required:

1. Metered data on solar or wind electricity consumed at the crude oil production or transport facilities during the ~~quarter~~reporting period (kWh);

2. Metered data on total electricity consumed at the crude oil production or transport facilities during the ~~quarter~~reporting period (kWh); and

3. An attestation letter stating that all solar or wind electricity was supplied directly for crude oil production or transport and that the solar or wind electricity reported for generating LCFS credit did not produce renewable energy certificates or other environmental attributes recognized or credited by any other jurisdiction or regulatory program, other than the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

(E) For solar steam projects at crude oil production facilities, the following additional recordkeeping and reporting will be required:

1. Metered data on solar steam consumed for crude oil production at the oil field during the ~~quarter~~reporting period (barrels cold water equivalent);

2. Metered data on total steam consumed for crude oil production at the oil field during the ~~quarter~~reporting period (barrels cold water equivalent);

3. Volume-weighted average steam quality for solar steam consumed for crude oil production at the oil field during the ~~quarter~~reporting period; and

4. An attestation letter stating that all solar steam was supplied directly for crude oil production at the oil field and that the solar steam reported for generating LCFS credit did not produce renewable energy certificates or other environmental attributes recognized or credited by any other jurisdiction or regulatory program, other than the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

(F) Any additional records that the Executive Officer requires to be kept in pursuant to section 95489(c)(3)(D), and records that demonstrate compliance with all special limitations and operating conditions specified pursuant to section 95489(c)(3)(D).

These records shall be submitted to the Executive Officer during the quarterly or annual reporting period specified in section 95491(b).

(5) *Credits for Producing or Transporting Crude Oil Using Innovative Methods.* Credits for producing or transporting crude oil using innovative methods may be generated quarterly or annually, at the discretion of the credit generating party. ~~Within 30 days of~~After receiving reports from California refineries detailing crude names and volumes supplied to the refineries during the applicable crediting period, any records requested of the applicant under section 95489(c)(4), and a positive or qualified positive verification of the applicable Project Reports per section 95500, the Executive Officer will determine the number of credits to be issued to the crude oil producer or transporter, joint applicant, or purchasing refinery for the innovative method. An adverse verification statement would result in no credit issuance and Executive Officer investigation. Except for carbon capture and sequestration (CCS) projects, the crediting period for projects eligible for credit generation pursuant to section 95489(c) will end no later than December 31, 2040.

(d) *Low-Complexity/Low-Energy-Use Refinery Credit.* A refinery may receive credit for being a low-complexity and low-energy-use refinery.

(1) To be eligible for the credit calculation in section 95489(d)(3), a Low-Complexity/Low-Energy-Use Refinery must meet the criteria in the definition of “Low-Complexity/Low-Energy-Use Refinery” provided in section 95481(a) using the following equations:

(A) Modified Nelson Complexity Score

$$Modified\ Nelson\ Complexity\ Score = \sum_{i}^{n} (index_i)\left(\frac{Capacity_i}{Capacity_{dist}}\right)$$

where:

$index_i$ is the 2012 Nelson Complexity Index listed in Table 10;

$Capacity_i$ is the capacity of each unit listed in Table 10 in barrels per day unless otherwise indicated;

$Capacity_{dist}$ is the capacity of the distillation unit in barrels per day;

i is the process unit; and

n is the total number of process units.

Table 10. Nelson Complexity Indices.

Process Unit	***Index Value***
Atmospheric Distillation	1.00
Vacuum Distillation	1.30
Thermal Processes	2.75
Delayed and Fluid Coking	7.50
Catalytic Cracking	6.00
Catalytic Reforming	5.00
Catalytic Hydrocracking	8.00
Catalytic Hydrorefining/Hydrotreating	2.50
Alkylation	10.00
Polymerization	10.00

Process Unit	Index Value
Aromatics	20.00
Isomerization	3.00
Oxygenates	10.00
Hydrogen (MMcfd)	1.00
Sulfur Extraction (Metric Tons per day)	240.00

(B) Annual Energy Use

$$Annual\ Energy\ Use\ (in\ MMBtu) = fuel\ use + electricity + thermal$$

where:

$fuel\ use$ is the MMBtu of all fuel combusted during the compliance period;

$electricity$ is the imported electricity minus exported electricity per compliance period converted to MMBtu by using 3.142 MMBtu/MWh; and

$thermal$ is the imported thermal energy minus exported thermal energy per compliance period in MMBtu.

(2) In addition to other reporting requirements, a refinery operator that is claiming credits for a Low-Complexity/Low-Energy-Use Refinery must also report the following volumes produced during a specific calendar year and sold, supplied, or offered for sale in California for that refinery:

(A) The volume of CARBOB and volume of diesel produced from crude oil;

(B) The volume of CARBOB and volume of diesel produced from transmix;

(C) The volume of CARBOB and volume of diesel produced from Petroleum Intermediate feedstocks; and

(D) The volume of CARBOB and volume of diesel purchased for blending.

(E) If CARBOB or diesel is produced from feedstock other than crude oil (volumes in (2)(B) through (D), above), a separate annual report with third-party verification is required for produced volumes of CARBOB and diesel from crude oil. The annual report must be submitted by ~~March 31st~~April 30 and the verification statement is due August 31~~st~~.

(3) Credits for a low-complexity/low-energy-use refinery must be calculated using the following equations:

(A) *Carbon Intensity Adjustment.* For volumes reported in section 95489(d)(2)(A) a non-transferable credit of 5.0 gCO_2e/MJ will be generated.

(B) *Credit Calculation.* For CARBOB and diesel volumes reported in section 95489(d)(2)(A):

$$Credits^{XD}_{LC-LE} = 5\ gCO2e/MJ \times VF^{XD} \times E^{XD} \times C$$

where:

$Credits^{XD}_{LC-L}$ is the amount of LCFS credits generated (a zero or positive value), in metric tons, by a fuel or blendstock under the average carbon intensity requirement for gasoline (XD = “gasoline”) or diesel (XD = ”diesel”);

VF^{XD} means the volume fraction of CARBOB (XD = “CARBOB”) or diesel (XD = “diesel”) fuel that is derived from crude oil supplied to the Low-Complexity/Low-Energy-Use refinery. VF^{XD} is calculated by dividing the volume of CARBOB or diesel reported for section 95489(d)(2)(A) by the total volume of CARBOB or diesel reported for section 95489(d)(2)(A) through (D);

E^{XD} is the amount of fuel energy, in MJ, from CARBOB (XD = “CARBOB”) or diesel (XD = “diesel”), determined from the energy density conversion factors in Table 4, either produced in California or imported into California during a specific calendar year and sold, supplied, or offered for sale in California; and

$$C = 1.0 \times 10^{-6} \frac{MT}{gCO_2e}$$

(C) Credits created pursuant to section 95489(d) may not be sold or transferred to any other party.

(4) *Application Contents and Submittal.* An application for Low-Complexity/Low-Energy-Use Refinery Credits must comply with the following requirements:

(A) An application must contain the following summary material:

1. A complete description of the refinery including processing units and their capacity, and energy use;

2. An engineering drawing(s) or process flow diagram(s) that illustrates the project, relevant process equipment, and mass or volumetric flows necessary to calculate the Low-Complexity/Low-Energy-Use Refinery Credits; and

3. A preliminary estimate of the credit, calculated as required in section 95489(d)(3)(B), including descriptions and copies of production and operational data other technical documentation utilized in support of the calculation.

(B) An application must include a list of references covering all information sources used in the calculation of Low-Complexity/Low-Energy-Use Refinery Credits. The reference list must meet the requirements of section 95488.7(a)(2)(D).

(C) An application must include a signed transmittal letter from the applicant attesting to the veracity of the information in the application packet and declaring that the information submitted accurately represents the actual operation of the refinery. The transmittal letter must meet the requirements of section 95488.8(a)(3)(A) through (D).

(D) An applicant that submits any information or documentation in support of a proposed Low-Complexity/Low-Energy-Use Refinery Credit must include a written statement clearly showing that the applicant understands and agrees that all information in the application not identified as confidential business information is subject to public disclosure pursuant to California Code of Regulations, title 17, sections 91000 through 91022 and the California Public Records Act (Government Code, §§ .6250 et seq.), and that information claimed by the applicant to be confidential might later be disclosed under section 91022 if the Board determines the information is subject to disclosure.

(E) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the ~~AFP~~LRT-CBTS unless the Executive Officer has approved or requested another format.

(F) If there is a change to an approved Low-Complexity/Low-Energy-Use Refinery which could impact the eligibility of the refinery, the refinery operator must notify the Executive Officer in writing within 30 ~~business~~ days after the material change has occurred, and the previously-approved application shall become invalid 30 ~~business~~ days after the material change has occurred.

(5) *Credit Issuance.* The Executive Officer will issue Low-Complexity/Low-Energy-Use Refinery Credits annually for the prior year upon the completion of the following:

(A) Confirmation of eligibility by the Executive Officer based on the refinery energy use verified under MRR annually.

(B) Receipt of a positive or qualified positive verification statement for the quarterly fuel transactions reported pursuant to section 95489(d)(2). An adverse verification statement would result in no credit issuance and Executive Officer investigation.

(C) The crediting period for projects eligible for credit generation pursuant to section 95489(d) will end no later than December 31, 2040.

(e) *Refinery Investment Credit Program.* A refinery, or a hydrogen production facility physically providing hydrogen to a refinery, may receive credit for reducing greenhouse gas emissions from its facility. For projects at hydrogen production facilities not owned by the refinery, the refinery and hydrogen production facility must apply as joint applicants. Any such credits must be based on fuel volumes sold, supplied, or offered for sale in California as set forth below.

(1) *General Requirements*.

(A) The application for a refinery investment credit must be submitted during or after the year 2016 and must be approved pursuant to this section before the refinery or hydrogen production facility can receive credit. A project is eligible if the project completion date is on January 1, 2016 or later.

(B) The refinery investment credit project must occur within the boundaries of the refinery~~, unless it involves carbon capture from~~ or hydrogen production facility. Sequestration sites for CCS do not need to be on-site at the refinery.

(C) The applicant must demonstrate that any net increases in criteria air pollutant or toxic air contaminant emissions from the refinery investment credit project are mitigated in accordance with all local, state, and national environmental and health and safety regulations.

(D) The following project types are eligible for the refinery investment project credits:

1. CO_2 capture from existing anthropogenic sources at refineries, or at hydrogen production facilities that supply hydrogen to refineries, and subsequent geologic sequestration;

2. Use of renewable or low-CI electricity supplied behind the meter ~~that meets the requirements of 95488.8(h)(1);~~at refineries or at hydrogen production facilities;

3. Use of lower-CI process energy such as biomethane, renewable propane, and renewable coke, to displace fossil fuel at refineries or hydrogen production facilities;

4. Electrification at refineries or hydrogen production facilities that involves substitution of high carbon fossil energy input with grid electricity.

5. Process improvement projects that deliver a reduction in baseline refinery-wide greenhouse gas emissions as outlined in 95489(e)(1)(~~G)2.~~J). Greenhouse gas emissions reductions due to curtailment, simple maintenance; and crude oil switching that results in greenhouse gas reductions in the project system boundary without improvements in the processing units or equipment involved are not eligible. For the purposes of this section, curtailment is defined as an intentional operational and/or physical change exclusively for the reduction or cessation of total gasoline and gasoline blendstocks and diesel production at the refinery~~.~~ or hydrogen production at the hydrogen production facility. Curtailment does not include the coincidental rate reduction or shutdown of associated emitting equipment as part of a process improvement project or projects aimed primarily at optimizing refinery or hydrogen production efficiency.

(E) Credits must be pro-rated for years where the units within the project system boundary were non-operational. This pro-rating will consider the ~~calendar~~ days of operation relative to non-operation.

(F) Credits must be pro-rated if the hydrogen production facility ~~that captures CO_2~~ does not supply all of its hydrogen to the applicant refinery.

(G) Credits generated pursuant to section 95489(e)(1)(D)5. are subject to the following limitations:

1. Credits may not be used to meet more than 10 percent of any entity's annual compliance obligation. The Executive

Officer will exclude incremental deficits incurred pursuant to section 95489(b) when assessing this 10 percent limitation.

~~2. Each project must generate at least 10,000 credits or one percent of the facility's annual pre-project emissions, whichever is less.~~

~~3.~~2. Crediting is limited to 15 years from the quarter in which the Executive Officer approves the project's application.

(H) Projects that utilize carbon capture and sequestration are subject to the provisions of section 95490.

(I) The project operator must provide a written application to the Executive Officer. If the project involves lower-CI process energy or renewable or low-CI electricity produced by a third party and delivered to the refinery or hydrogen production facility, both the refinery or hydrogen production facility and the third party must apply and will be considered joint applicant project operator for approval of the project. If more than one refinery or hydrogen production facility receives lower-CI process energy or renewable or low-CI electricity from a single third-party facility, each refinery or hydrogen production facility must submit an independent application with the third party as a joint applicant on each submittal. If the project involves delivery of carbon captured by the refinery or hydrogen production facility to a third party to store the carbon, both the refinery or hydrogen production facility and the third party must apply and will be considered joint applicants for approval of the project.

(J) Applications submitted pursuant to section 95489(e)(1)(D) must demonstrate an emissions reduction of at least 10,000 metric tons CO_2e per year or one percent of the facility's annual pre project emissions, whichever is less.

(K) Renewable or low-CI energy sources listed in 95489(e)(1)(D) that are used to generate LCFS credit may not also claim renewable energy certificates or other environmental attributes recognized or credited by any other jurisdiction or regulatory program, other than the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Any renewable energy certificates or other environmental attributes associated with the energy must be retired on behalf of the LCFS.

(2) *Calculation of Credits*.

(A) For carbon capture and sequestration projects, determine the credit in accordance with sections 95489(e)(2), 95490, and the CCS protocol.

(B) For other refinery investment credit projects, determine the credit as follows:

1. Establish a project system boundary. The project system boundary should include direct impacts and at least first order indirect impacts;

2. Determine the credit for the refinery investment credit project by calculating pre-project life cycle greenhouse gas emissions and project life cycle greenhouse gas emissions within the project system boundary;

$$Credit_{RIP} = (GHG_{pre-project} - GHG_{post-project}) \times \frac{Volume^{XD}}{Volume^{Total}}$$

where:

$Credit_{RIP}$ is the annual credit for the refinery investment credit project in metric tons per year;

$GHG_{pre-project}$ is the annual life cycle greenhouse gas emissions from the use of fuels, electricity, steam/heat and hydrogen in the project system boundary prior to project implementation in metric tons per year corrected for downtime;

$GHG_{post-project}$ is the annual life cycle greenhouse gas emissions from the use of fuels, electricity, steam/heat and hydrogen in the project system boundary due to project implementation in metric tons per year corrected for downtime;

$Volume^{XD}$ is the volume of gasoline, gasoline blendstocks, and diesel in gallons per quarter or per year produced at the refinery and sold, supplied, or offered for sale in California by the refinery involved in the Refinery Investment Credit Program; and

$Volume^{Total}$ is the total volume of gasoline, gasoline blendstocks, and diesel in gallons produced at the refinery per quarter or per year.

(3) *Application Contents and Submittal.* Unless otherwise noted, an application for refinery investment credits must comply with the following requirements:

(A) An application must contain the following summary material:

1. A complete description of the refinery investment credit project and how emissions are reduced;

2. An engineering drawing(s) or process flow diagram(s) that illustrates the project and clearly identifies the system boundaries, relevant process equipment, mass flows, and energy flows necessary to calculate the refinery investment credits, including any directly affected or indirectly affected processing units (at least first order indirect impacts) and a whole refinery diagram if requested; and

3. A preliminary estimate of the refinery investment credit, calculated as required in section 95489(e)(2), including descriptions and copies of any available production and operational data including energy use and other technical documentation utilized in support of the calculation. The application must contain process-specific data showing that the reductions are part of the transportation fuel pathway.

4. Supporting documents demonstrating that second or higher order indirect impacts are not significant beyond the identified project system boundary.

(B) An application must include a list of references covering all information sources used in the calculation of refinery investment credit. The reference list must meet the requirements of section 95488.7(a)(2)(D).

(C) An application must include a signed transmittal letter from the applicant attesting to the veracity of the information in the application packet and declaring that the information submitted accurately represents the actual and/or intended long-term, steady-state operation of the refinery investment credit project described in the application packet. The transmittal letter must meet the requirements of section 95488.8(a)(3)(A) through (D).

(D) CBI must be designated and a redacted version of any submitted documents designated to include CBI must be provided pursuant to the requirements described in section 95488.8(c).

(E) An application must include all relevant documentation identifying any changes, including decreases or increases, in criteria air pollutant or toxic air contaminant emissions based on local air permits and supporting permit documentation from the refinery investment credit project. An applicant must include a signed transmittal letter from the applicant attesting that any net increases in emissions from the refinery investment credit project are mitigated in accordance with all local, state, and national environmental and health and safety regulations.

(F) An applicant that submits any information or documentation in support of a proposed refinery investment credit must include a written statement clearly showing that the applicant understands and agrees that all information in the application not identified as confidential business information is subject to public disclosure pursuant to California Code of Regulations, title 17, sections 91000 through 91022 and the California Public Records Act (Government Code, §§ .6250 et seq.), and that information claimed by the applicant to be confidential might later be disclosed under section 91022 if the Board determines the information is subject to disclosure.

(G) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the ~~AFP~~LRT-CBTS unless the Executive Officer has approved or requested another format.

(H) Applications for process improvement projects must be submitted on or before December 31, 2025.

(4) *Application Approval Process.* An application must be approved by the Executive Officer before the refinery investment credit project can generate credits under the LCFS regulation.

(A) After receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer will advise the applicant in writing either that:

1. The project system boundary is appropriate and the application is complete, or

2. The application is incomplete, in which case the Executive Officer will identify which requirements of section 95489(e) have not been met. The applicant may submit additional information to correct deficiencies identified by the Executive Officer. If the applicant is unable to achieve a complete application within 180 ~~calendar~~ days of the Executive Officer's receipt of the original application, the application will

be denied on that basis, and the applicant will be informed in writing.

(B) ~~After accepting an application as complete, the Executive Officer will post the application at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm.~~ If the Executive Officer deems the application ready for validation, the applicant will be notified accordingly and provided with a list of eligibility requirements and comparison baseline inputs required for validation. The applicant must seek the services of an Executive Officer accredited verification body for validation as specified in section 95500 before the application can be accessed by the verification body. A positive or qualified positive validation statement must be received by the Executive Officer from the verification body in order for CARB's evaluation and certification of the project application to proceed. In cases where a single applicant or a joint applicant does not complete validation, the application will be denied without prejudice. In cases where an applicant cannot complete validation within six months of the verification body receiving the application from CARB, or receives an adverse validation statement, the application will be denied without prejudice.

~~(B)~~(C) After receiving a positive or qualified positive validation statement, the Executive Officer will post the application at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm. Public comments will be accepted for ~~10 calendar~~14 days following the date on which the application was posted. Only comments related to potential factual or methodological errors may be considered. The Executive Officer will forward to the applicant all comments identifying potential factual or methodological errors. Within 30 ~~business~~ days, the applicant must either submit revisions to its application to the Executive Officer, or submit a detailed written response to the Executive Officer explaining why no revisions are necessary.

~~(C)~~(D) If the Executive Officer finds that an application meets the requirements set forth in section 95489(e), the Executive Officer will take final action to approve the refinery investment credit project. The Executive Officer may prescribe conditions of approval that contain special limitations, recordkeeping and reporting requirements, and operational conditions that the Executive Officer determines should apply to the project. If the Executive Officer finds that an application does not meet the requirements of section 95489(e), the application will not be approved, and the applicant will be notified in writing, and the basis for the disapproval will be identified.

(E) ~~*Credit Review and Issuance.*~~The Executive Officer shall not approve an application if the Executive Officer determines, based upon the information submitted in the application and any other available information, that:

1. The proposed project does not meet the requirements set forth in section 95489(e).

2. Based upon the application information submitted pursuant to this section, the applicant's greenhouse gas emissions calculations cannot be replicated.

(5) *Reporting, Credit Review, and Issuance.* For each approved refinery investment credit project, the regulated entity must report quarterly or annually through a Project Report. A regulated entity electing to report annually is required to submit its annual Project Report to CARB for the previous compliance year by April 30 of each year. Credits for refinery investment projects may be generated quarterly or annually, at the discretion of the credit generating party.

(A) Upon the completion of reporting period in which a positive or qualified positive verification statement for the applicable Project Reports per section 95500(e) is received, the Executive Officer will determine the number of credits to be issued to the applicants. An adverse verification statement would result in no credit issuance and Executive Officer investigation.

(B) Except for CCS projects, the crediting period for projects eligible for credit generation pursuant to section 95489(e) will end no later than December 31, 2040.

(6) *Recordkeeping.* For each approved refinery investment credit project, the ~~refinery~~regulated entity must compile and retain records pursuant to section 95491.1(a)(2) showing compliance with all limitation and recordkeeping requirements identified by the Executive Officer pursuant to section 95489(e)(4)(~~C~~E), above.

(f) *Renewable Hydrogen Refinery Credit Program.* A refinery, or a hydrogen production facility physically providing hydrogen to a refinery, may receive credit for greenhouse gas emission reductions from the production of CARBOB or diesel fuel that is partially or wholly derived from renewable hydrogen. For projects at hydrogen production facilities not owned by the refinery, the refinery and hydrogen production facility must apply as joint applicants. Any such credits must be based on fuel volumes sold, supplied, or offered for sale in California as set forth below.

(1) *General Requirements*.

(A) In order to receive a renewable hydrogen refinery credit, a refiner must produce CARBOB or diesel fuel that is partially or wholly derived from renewable hydrogen.

(B) The applicant must demonstrate that any net increases in criteria air pollutant or toxic air contaminant emissions from the renewable hydrogen refinery credit project are mitigated in accordance with all local, state, and national environmental and health and safety regulations.

(C) The project operator must submit a written application to the Executive Officer. If the project involves renewable natural gas or electricity produced by a third party and delivered to the refinery or hydrogen production facility, both the refinery or hydrogen production facility and the third party must apply and will be considered joint applicant project operator for approval of the project. If more than one refinery or hydrogen production facility receives renewable natural gas or electricity from a single third-party facility, each refinery or hydrogen production facility must submit an independent application with the third party as a joint applicant on each submittal.

(D) Applications submitted pursuant to section 95489(f) must demonstrate a generation of at least 10,000 credits or one percent of the facility's annual pre-project emissions, whichever is less.

(E) Renewable or low-CI energy sources that are used to produce renewable hydrogen and generate LCFS credit may not also claim renewable energy certificates or other environmental attributes recognized or credited by any other jurisdiction or regulatory program, other than the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Any renewable energy certificates or other environmental attributes associated with the energy used to produce renewable hydrogen must be retired on behalf of the LCFS.

(2) *Calculation of Credits*.

(A) For CARBOB or diesel fuel that is partially or wholly derived from renewable hydrogen produced from RNG that displaces fossil natural gas in a steam methane reforming unit, the calculation of credits generated quarterly or annually must be as follows:

$$Credits^{H}_{RIC} = (CI_{NG} - CI_{RNG}) \times E_{RNG} \times C \times \frac{Volume^{XD}}{Volume^{Total}}$$

where:

$Credits^{H}_{RIC}$ is the amount of LCFS credits generated (a zero or positive value), in metric tons, by renewable hydrogen;

CI_{NG} is the well-to-hydrogen production carbon intensity of North American pipeline natural gas in gCO_2e/MJ calculated using the same feedstock assumptions and pipeline distance as the Lookup Table pathway for Pipeline Average North American Fossil Natural Gas (CNGF);

CI_{RNG} is the well-to-hydrogen production carbon intensity of the RNG in gCO_2e/MJ and must be determined using the CA~~-GREET 3~~-GREET4.0- model unless the Executive Officer has approved the use of a method that is at least equivalent to the calculation methodology used by CA~~-~~-GREET~~3~~4.0 model. The process for obtaining CI_{RNG} will be identical to Tier 2 fuel pathway applications, and the life cycle steps evaluated will stop at hydrogen production at the refinery;

E_{RNG} is the amount of RNG in MJ ~~delivered~~that displaces fossil natural gas for hydrogen production at a refinery or a facility providing hydrogen to a refinery per quarter or per year;

$Volume^{XD}$ is the volume of gasoline, gasoline blendstocks, and diesel in gallons per quarter or per year produced at the refinery and sold, supplied, or offered for sale in California by the refinery;

$Volume^{Total}$ is the total volume of gasoline, gasoline blendstocks, and diesel in gallons produced at the refinery per quarter or per year; and

$$C = 1.0 \times 10^{-6} \frac{MT}{gCO2e}$$

(B) For CARBOB or diesel fuel that is partially or wholly derived from renewable hydrogen produced from other production processes, such as electrolysis using renewable electricity or syngas from biomass gasification, the calculation of credits generated quarterly or annually must be as follows:

$$Credits^{H}_{RIC} = (CI^{H}_{Fossil} - CI^{H}_{Renewable}) \times D^{H}_{Renewable} \times M^{H}_{Renewable} \times C \times \frac{Volume^{XD}}{Volume^{Total}}$$

where:

$Credits^{H}_{RIC}$ is the amount of LCFS credits generated (a zero or positive value), in metric tons, by renewable hydrogen;

CI^{H}_{Fossil} is the carbon intensity of fossil hydrogen in gCO_2e/MJ delivered or produced at the refinery, as determined using the CA~~-~~-

GREET~~3~~4.0 model or similar models approved by the Executive Officer. The process for obtaining CI^{H}_{Fossil} must comply with the requirements in sections 95488 to 95488.10;

$CI^{H}_{Renewable}$ is the carbon intensity of renewable hydrogen in gCO_2e/MJ delivered or produced at the refinery, as determined using the CA-GREET~~3~~4.0 model. The process for obtaining $CI^{H}_{Renewable}$ must comply with the requirements in sections 95488 to 95488.10;

$M^{H}_{Renewable}$ is the amount of renewable hydrogen in kg per quarter or per year;

$D^{H}_{Renewable}$ is the energy density of hydrogen in MJ/kg from Table 4;

$Volume^{XD}$ is the volume of gasoline, gasoline blendstocks, and diesel in gallons per quarter or per year sold, supplied, or offered for sale in California by the refinery involved in the Renewable Hydrogen Refinery Credit Program;

$Volume^{Total}$ is the total volume of gasoline, gasoline blendstocks, and diesel in gallons produced at the refinery per quarter or per year; and

$$C = 1.0 \times 10^{-6} \frac{MT}{gCO2e}$$

(3) *Application Contents and Submittal.* Unless otherwise noted, an application for renewable hydrogen credits must comply with the following requirements:

(A) An application must contain the following summary material:

1. A complete description of the production of CARBOB or diesel fuel with hydrogen and how renewable hydrogen is replacing fossil hydrogen in that process;

2. Purchase records identifying the renewable hydrogen and/or renewable feedstock used to produce the renewable hydrogen; and

3. A preliminary estimate of the renewable hydrogen refinery credit, calculated as required in section 95489(f)(2), including descriptions and copies of production and operational data, including energy use, and other technical documentation utilized in support of the calculation. The application must contain process-specific data showing that the reductions are part of the transportation fuel pathway.

(B) An application must include a list of references covering all information sources used in the calculation of renewable hydrogen refinery credit project. The reference list must meet the requirements of section 95488.7(a)(2)(D).

(C) An application must include a signed transmittal letter from the applicant attesting under penalty of perjury under California law, to the veracity of the information in the application packet and declaring that the information submitted accurately represents the actual and/or intended long-term, steady-state operation of renewable hydrogen refinery credit project described in the application packet. The transmittal letter must meet the requirements of section 95488.8(a)(3)(A) through (D).

(D) CBI must be designated and a redacted version of any submitted documents designated to include CBI must be provided pursuant to the requirements described in section 95488.8(c).

(E) An application must include all relevant documentation identifying any changes, including decreases or increases, in criteria air pollutant or toxic air contaminant emissions based on local air permits from the renewable hydrogen refinery credit project. An applicant must include a signed transmittal letter from the applicant attesting that any net increases in emissions from renewable hydrogen refinery credit project are mitigated in accordance with all local, state, and national environmental and health and safety regulations.

(F) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the ~~AFP~~LRT-CBTS unless the Executive Officer has approved or requested another format.

(4) *Application Approval Process.* An application must be approved by the Executive Officer before the renewable hydrogen refinery credit project can generate credits under the LCFS regulation.

(A) ~~Within 30 calendar days of~~Following receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer will advise the applicant in writing either that:

1. The application is complete, or

2. The application is incomplete, in which case the Executive Officer will identify which requirements of section 95489(f) have not been met. The applicant may submit additional information to correct deficiencies identified by the Executive Officer. If the applicant is unable to achieve a complete

application within 180 days of the Executive Officer's receipt of the original application, the application will be denied on that basis, and the applicant will be informed in writing.

(B) If the Executive Officer deems the application ready for validation, the applicant will be notified accordingly and provided with a list of eligibility requirements and comparison baseline inputs required for validation. The applicant must seek the services of an Executive Officer accredited verification body for validation as specified in section 95500 before the application can be accessed by the verification body. A positive or qualified positive validation statement must be received by the Executive Officer from the verification body in order for CARB's evaluation and certification of the project application to proceed. In cases where a single applicant or a joint applicant does not complete validation, the application will be denied without prejudice. In cases where an applicant cannot complete validation within six months of the verification body receiving the application from CARB, or receives an adverse validation statement, the application will be denied without prejudice.

(C) After receiving a positive or qualified positive validation statement, the Executive Officer will post the application at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm. Public comments will be accepted for 14 days following the date on which the application was posted. Only comments related to potential factual or methodological errors may be considered. The Executive Officer will forward to the applicant all comments identifying potential factual or methodological errors. Within 30 days, the applicant must either submit revisions to its application to the Executive Officer, or submit a detailed written response to the Executive Officer explaining why no revisions are necessary.

(D) The Executive Officer shall not approve an application if the Executive Officer determines, based upon the information submitted in the application and any other available information, that:

1. The proposed project does not meet the requirements set forth in section 95489(f).

2. Based upon the application information submitted pursuant to this section, the applicant's greenhouse gas emissions calculations cannot be replicated.

~~(B)~~(E) If the Executive Officer finds that an application meets the requirements set forth in section 95489(f), the Executive Officer will take final action to approve the renewable hydrogen refinery credit project. The Executive Officer may prescribe conditions of approval that contain special limitations, recordkeeping and reporting requirements, and operational conditions that the Executive Officer determines should apply to the project. If the Executive Officer finds that an application does not meet the requirements of section 95489(f), the application will not be approved, and the applicant will be notified in writing, and the basis for the disapproval will be identified.

(5) ~~*Credit Review and Issuance.*~~*Reporting, Credit Review, and Issuance.* For each approved renewable hydrogen refinery credit project, the regulated entity must report quarterly or annually through a Project Report. A regulated entity electing to report annually is required to submit its annual Project Report to CARB for the previous compliance year by April 30 of each year. Credits for renewable hydrogen refinery projects may be generated quarterly or annually, at the discretion of the credit generating party.

(A) Upon the completion of reporting period in which a positive or qualified positive verification statement for the applicable Project Reports per section 95500(e) is received, the Executive Officer will determine the number of credits to be issued to the applicants. An adverse verification statement would result in no credit issuance and Executive Officer investigation.

(B) The crediting period for projects eligible for credit generation pursuant to section 95489(f) will end no later than December 31, 2040.

(6) *Recordkeeping.* For each approved renewable hydrogen refinery credit project, the ~~refinery~~regulated entity must compile and retain records pursuant to section 95491.1(a)(2) showing compliance with all limitation and recordkeeping requirements identified by the Executive Officer pursuant to section 95489(f)(4)(~~B~~E), above.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95490. Provisions for Fuels Produced Using Carbon Capture and Sequestration.

(a) *Eligibility.* The following entities are eligible to submit ~~project~~ applications and, if approved, receive ~~CCS~~ credits associated with net GHG reductions from CCS projects, in accordance with following protocol which is incorporated herein by reference and is referred to as the “CCS Protocol” hereafter.

Industrial Strategies Division, California Air Resources Board. August 13, 2018. Carbon Capture and Sequestration Protocol under the Low Carbon Fuel Standard.

(1) Alternative fuel producers, petroleum refineries, and oil ~~and gas~~ producers that capture CO_2 on-site, including at the location of the production of hydrogen used as an intermediate input, and geologically sequester CO_2 either on-site or off-site.

(2) An entity that employs direct air capture to remove CO_2 from the atmosphere using chemical and/or physical separation and geologically sequester the CO_2~~.~~

(A) Direct air capture and sequestration projects must be physically located in the United States.

~~(2)~~(B) If CO_2 derived from direct air capture is converted to fuels, it is not eligible for project-based CCS credits. However, applicants may apply for fuel pathway certification using the Tier 2 pathway application process as described in section 95488.7.

(b) *General Requirements*.

(1) Projects and fuel pathways claiming CCS credits must comply with the CCS Protocol. To be considered in compliance with the CCS protocol, a project must be issued executive orders and meet all the requirements throughout the project life in accordance with the permanence requirements of the CCS protocol.

(2) Credit determination for any project that utilizes CCS must be performed in accordance with the accounting requirements of the CCS protocol.

(3) Except for direct air capture and sequestration projects, credits must be prorated based on the volumes delivered to California.

(4) CCS credits generated by crude oil ~~and gas~~ producers must be claimed under the Innovative Crude Provision (section 95489(c)).

(5) CCS credits ~~generated~~ by refiners must be claimed under the Refinery Investment Credit Program (section 95489(e)).

(6) ~~The amount~~A Tier 2 pathway application must be submitted pursuant to section 95488.7 to capture the GHG reduction benefit of ~~net CO_2 sequestered by~~CCS associated with alternative fuel producers ~~can be~~

~~used to adjust the carbon intensities~~. The GHG reduction benefit of CCS is reflected in the ~~associated~~ CI score of the Tier 2 fuel pathway~~s~~.

(7) Projects utilizing CCS must undergo verification under section 95500 in order to receive credits.

(8) For direct air capture operations only, the greenhouse gas emissions for electricity used by the capture facility must be calculated as follows:

(A) For electricity generated onsite (i.e., behind the meter), the greenhouse gas emissions must be calculated using the CA-GREET4.0 emission factors for the specific electricity supply.

(B) Grid electricity used in direct air capture can be claimed as low-CI electricity as specified in section 95488.8(i)(1)(C).:

(C) If new or expanded purchased low-CI electricity cannot be demonstrated, the greenhouse gas emissions must be calculated using CA-GREET4.0 (e.g., eGRID U.S. subregion if applicable) emission factors.

(c) *Application Contents and Submittal.* Unless otherwise noted, an application for CCS credits must comply with the following requirements:

(1) An application must be filed jointly by an entity that captures CO_2, an entity that transports the CO_2, and an entity that sequesters the resultant CO_2, unless the same entity is responsible for CO_2 capture, transport, and sequestration.

(2) An application must contain the following materials:

(A) A complete description of the CCS project and how greenhouse gas emissions are reduced; to be eligible for LCFS credits, a CCS project sequestering CO_2 that is already being captured and used productively in industry must demonstrate a net reduction in greenhouse gas emissions by providing evidence that the marginal new source of CO_2 replacing the prior industrial use is newly installed or expanded capture from anthropogenic sources;

(B) An engineering drawing(s) or process flow diagram(s) that illustrates the project and clearly identifies the system boundaries, relevant process equipment, mass flows, including the quantity of CO_2 injected into pipeline or delivered by other modes of transport for CO_2 injection, and energy flows necessary to calculate the CCS credit;

(C) A description of all combustion and electricity-powered equipment within the system boundaries, including their respective capacities, sizes, or rated power, fuel utilization type, fuel shares, energy efficiency (lower heating value basis), and proposed use;

(D) A description of all sources of flared, vented, and fugitive emissions within the system boundaries, including the compositions and quantities of the flared, vented, and fugitive emission streams leaving the system boundaries;

(E) Receipts/invoices for energy use and chemicals;

(F) An estimate of the CCS credit, calculated in accordance with the accounting requirements of the CCS Protocol including descriptions and copies of production and operational data or other technical; and documentation utilized in support of the calculation. The application must contain process-specific data showing that the reductions are part of the CCS project, and

(G) Executive orders issued pursuant to the permanence requirements of the CCS protocol, certifying the sequestration site as capable of permanently storing CO_2 and authorizing operation and credit generation.

(3) An application must include a list of references covering all information sources used in the calculation of the CCS credit. The reference list must meet the requirements of section 95489(c)(2)(E).

(4) An application must include a signed transmittal letter from the applicant attesting to the veracity of the information in the application packet and declaring that the information submitted accurately represents the actual CCS project greenhouse gas emissions reductions. The transmittal letter must be the original copy, be on company letterhead, be signed by an officer of the applicant with authority to attest to the veracity of the information in the application and to sign on behalf of the applicant.

(5) CBI must be designated and a redacted version of any submitted documents designated to include CBI must be provided pursuant to the requirements described in section 95488.8(c).

(6) An applicant that submits any information or documentation in support of a proposed CCS project must include a written statement clearly showing that the applicant understands and agrees that all information in the application not identified as confidential business information is subject to public disclosure pursuant to California Code of Regulations, title 17, sections 91000 through 91022 and the California Public Records Act (Government Code, §§ 6250 et seq.), and that information claimed by the applicant to be confidential might later be disclosed under section 91022 if the Board determines the information is subject to disclosure.

(7) An application, supporting documents, and all other relevant data or calculation or other documentation must be submitted electronically via the AFP unless the Executive Officer has approved or requested another format.

(d) *Application Approval Process.* The Executive Officer must approve an application before the CCS project can generate credits under the LCFS regulation.

(1) After receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer will advise the applicant in writing either that:

(A) The application is complete, or

(B) The application is incomplete, in which case the Executive Officer will identify which requirements have not been met. The applicant may submit additional information within 30 days to correct deficiencies identified by the Executive Officer, otherwise, the application will be rejected.

(2) After accepting an application as complete, the Executive Officer will post the application on the LCFS ~~web site~~website. Public comments will be accepted for ~~10 calendar~~14 days following the date on which the application was posted. Only comments related to potential factual or methodological errors may be considered. The Executive Officer will forward to the applicant all comments identifying potential factual or methodological errors. Within 30~~ business~~ days, the applicant must either submit revisions to its application to the Executive Officer, or submit a detailed written response to the Executive Officer explaining why no revisions are necessary.

(3) If the Executive Officer finds that an application meets the requirements set forth in section 95490(b), the Executive Officer will take final action to approve the CCS project. The Executive Officer may prescribe conditions of approval that contain special limitations, recordkeeping and reporting requirements, and operational conditions that the Executive Officer determines should apply to the project. If the Executive Officer finds that an application does not meet the requirements of section 95490(b), the application will not be approved, the applicant will be notified in writing, and the basis for the disapproval will be identified.

(e) *Reporting.* Each CCS project operator must ~~submit~~report to the Executive Officer the net amount of annual sequestered CO_2 and meet ~~the~~all other applicable reporting requirements in accordance with the CCS Protocol~~.~~ and section 95490(d)(3).

(f) *Credit Review and Issuance.* ~~Credits for~~ A CCS project can receive LCFS credits either under the project-based provisions or through a Tier 2 fuel pathway.

~~(f)~~(1) For each approved CCS innovative crude project (section 95489(c)(1)(A)2.), refinery investment credit project (section 95489(e)(1)(D)1.), or direct air capture and sequestration project (section 95490(a)(2)), the regulated entity must report quarterly or annually through a Project Report. A regulated entity electing to report annually is required to submit its annual Project Report to CARB for the previous compliance year by April 30 of each year. Credits for these projects may be generated quarterly or annually, ~~at the discretion of the credit generating party.~~consistent with the reporting schedule.

~~(1)~~Upon the completion of reporting period in which a positive or qualified positive verification statement for the applicable Project R ports per section 95500(e) is received, the Executive Officer will determine the number of credits to be issued to the applicants. An adverse verification statement would result in no credit issuance and Executive Officer investigation.

(2) For a certified Tier 2 fuel pathway that incorporates a CCS project, credits for fuel transactions reported quarterly using the certified pathway CI will be generated for the given quarter, pursuant to section 95486.1. Fuel pathway holders must include the operational data from the fuel production and the CCS project in their Annual Fuel Pathway Reports, pursuant to section 95488.10. Entities required to obtain verification of their Annual Fuel Pathway Reports must comply with the requirements in section 95500(b).

(g) *Recordkeeping.* Pursuant to section 95491.1 and the CCS Protocol, each applicant that receives approval as a CCS credit generator must maintain records for the CCS project, including records necessary to verify permanent sequestration. At a minimum, the following records must be kept:

(1) The quarterly volume of alternative fuel, petroleum fuel, crude oil/natural gas produced and delivered to California;

(2) Energy use and chemical use data for the carbon capture facility and CO_2 injection facility;

(3) The Accounting Protocol and Permanence Protocol documents; and

(4) Any additional records that the Executive Officer requires to be kept in pursuant to section 95490(d)(3).

(h) *CO_2 Leakage and Credit Invalidation*.

(1) Credits for verified greenhouse gas emission reductions can be invalidated if the sequestered CO_2 associated with them is released or otherwise leaked to the atmosphere.

(2) The number of invalidated credits is equal to the quantity of CO_2 released or leaked from the sequestration zone ($CO_2^{leakage}$), which must be determined in accordance with the CCS Protocol.

(3) Prior to 50 years post-injection:

(A) The Executive Officer may retire credits from the buffer account, up to and including the project's total contribution, to count toward the number of invalidated credits.

(B) The project operator must retire credits for any balance after retiring credits pursuant to 95490(h)(3)(A).

(C) The Executive Officer may retire credits from the buffer account equivalent to remaining outstanding balance after retiring credits pursuant to 95490(h)(3)(A) and (B).

(4) After 50 years post-injection:

(A) The project operator is no longer responsible to make up any credits found to be invalid due to leakage.

(B) The Executive Officer may retire credits from the buffer account to cover any credits found to be invalid due to leakage.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95491. Fuel Transactions and Compliance Reporting.

A fuel reporting entity must submit to the Executive Officer Quarterly Fuel Transactions Reports and Annual Compliance Reports, as specified in this section.

(a) *Online Reporting.* The annual compliance and quarterly fuel transactions reports must be submitted using the LRT-CBTS. Prior to use, a fuel reporting entity must first register in the LRT-CBTS pursuant to section 95483.2.

The fuel reporting entity is solely responsible for ensuring that the Executive Officer receives its quarterly fuel transactions reports and annual compliance reports by the deadlines specified in this section. The Executive Officer shall not be responsible for failure of electronically submitted reports to be transmitted to the Executive Officer. The reports must contain a statement attesting to the report's accuracy and validity. The Executive Officer shall not deem an electronically submitted report to be valid unless the report is accompanied by a digital signature that meets the requirements of California Code of Regulations, title 2, sections 22000 et seq.

(b) *Reporting Frequency and Deadlines*.

(1) *Quarterly Fuel Transactions Data:* The data for the quarterly fuel transactions report for each fuel type must be uploaded in the LRT-CBTS within the first 45 days after the end of the quarter. During the subsequent 45 days, fuel reporting entities shall use the reconciliation tools provided in the LRT-CBTS and in conjunction with business partners to complete any necessary report corrections, if applicable.

(2) *Quarterly Fuel Transactions Reports.* Unless expressly provided elsewhere in this subarticle, quarterly fuel transactions reports must be submitted in LRT-CBTS by:

June 30~~th~~ - for the first calendar quarter covering January through March;

September 30~~th~~ - for the second calendar quarter covering April through June;

December 31~~st~~ - for the third calendar quarter covering July through September; and

March 31~~st~~ - for the fourth calendar quarter of the prior year covering October through December.

(3) *Annual Compliance Reports.* An annual compliance report for the prior calendar year must be submitted in LRT-CBTS by April 30~~th~~ of each year.

(c) *General Reporting Requirements for Quarterly Fuel Transactions Reports.* For each of its transportation fuels, a fuel reporting entity must submit a quarterly fuel transactions report that contains the information specified below and summarized in Table 11:

(1) All applicable transaction types listed for each fuel type in 95491 (d) below and defined in section 95481 must be included in each quarterly fuel transactions report.

(2) Information that must be reported are as follows: Organization FEIN, Reporting Period (year and quarter), FPC, Fuel Amount, Transaction Type, Transaction Date, Business Partner (if applicable), Aggregated Transaction Indicator, Fuel Application, Production Company ID and Facility ID (if applicable).

(d) *Specific Reporting Requirements for Quarterly Fuel Transactions Reports.* In addition to all requirements specified in section 95491(c), for each of its transportation fuels, a fuel reporting entity must submit a quarterly fuel transactions report that contains the information specified below and summarized in Table 11:

(1) *Specific Quarterly Reporting Parameters for Liquid Fuels including Gasoline, Diesel, Diesel Fuel Blends, Fossil Jet Fuel, and Alternative Fuels, and Alternative Jet Fuel*.

(A) The applicable transaction types, defined in section 95481, are as follows: Production in California, Production for Import, Import, Purchased with Obligation, Purchased without Obligation, Sold with Obligation, Sold without Obligation, Export, Loss of Inventory, Gain of Inventory, and Not Used for Transportation. The transaction type "Production for Import" is to be reported by out-of-state producers who choose to be the first fuel reporting entity for fuel imported into California. The transaction type "Import" is to be reported by non-producers who choose to be the first fuel reporting entity for out-of-state fuel imported into California. The following information are to be reported:

1. Production Company ID and Facility ID for each blendstock. CARBOB and diesel fuel are exempt from this requirement.

2. The certified fuel pathway code (FPC) of each blendstock.

3. The volume (in gal) of each blendstock per reporting period. For purposes of this provision only, except as provided in subsection 4. below, the fuel reporting entity may report the total volume of each blendstock aggregated for each distinct carbon intensity value (e.g., X gallons of blendstock with A gCO_2e/MJ, Y gallons of blendstock with B gCO_2e/MJ).

4. A producer of CARBOB, gasoline, or diesel fuel must report, for each of its refineries, the MCON or other crude oil name designation, volume (in gal), and Country (or State) of origin for each crude supplied to the refinery during the quarter.

(B) *Temperature Correction.* All liquid fuel volumes reported in the LRT-CBTS must be adjusted to standard temperature conditions of 60°F as follows:

1. For ethanol, the following formula must be used:

$$V_{s,e} = V_{a,e} \times (-0.0006301 \times T + 1.0378)$$

where:

$V_{s,e}$ is the standardized volume of ethanol at 60°F, in gallons;

$V_{a,e}$ is the actual volume of ethanol, in gallons; and

T is the actual temperature of the batch, in °F.

2. For biodiesel, one of the following two methodologies must be used:

   a. $V_{s,b} = V_{a,b} \times (-0.00045767 \times T + 1.02746025)$

      where:

      $V_{s,b}$ is the standardized volume of biodiesel at 60°F, in gallons;

      $V_{a,b}$ is the actual volume of biodiesel, in gallons; and

      T is the actual temperature of the batch, in °F.

   b. The standardized volume of biodiesel at 60°F, in gallons, as calculated from the use of the American Petroleum Institute Refined Products Table 6B, as referenced in ASTM D1250-08 (Reapproved 2013), which is incorporated herein by reference, or by comparable means that can be demonstrated to a verifier or the Executive Officer to be consistent with these standard methods.

3. For other liquid fuels, the volume correction to standard conditions must be calculated by the methods described in the American Petroleum Institute (API) Manual of Petroleum Measurement Standards Chapter 11 - Physical Properties Data (May 2004), the ASTM Standard Guide for Use of the Petroleum Measurement Tables, ASTM D1250-08 (Reapproved 2013), or the API Technical Data Book - Petroleum Refining Chapter 6 - Density (Sixth Edition, April 1997), all three of which are incorporated herein by reference, or by comparable means that can be demonstrated to a verifier or the Executive Officer to be consistent with these standard methods.

(C) *Fuel Pathway Allocation for Produced Fuel.* If a fuel production facility simultaneously processes multiple feedstocks, the producer or fuel reporting entity must associate each portion of the total fuel produced with processed feedstock during each reporting period (calendar quarter). Feedstock quantities must not be counted more than once for any fuel produced. The fuel reporting entity must use one of the following methods to allocate feedstock to the quantities of produced fuel reported under each certified FPC.

1. The quantity of fuel reported for a fuel pathway code must be determined using the following method:

   a. $Q^n_{Fuel\ i} = Y_{average\ yield} \times Q^n_{Feedstock\ i}$

      where:

      $Q^n_{Fuel\ i}$ is the quantity of produced fuel with a fuel pathway i at a production facility during reporting period n;

      $Y_{average\ yield}$ is the facility's average production yield for all feedstocks as determined during pathway certification; and

      $Q^n_{Feedstock\ i}$ is the quantity of feedstock counted as processed for a fuel pathway i at a production facility during reporting period n and the quantity of feedstock inventory associated with the fuel pathway i must be greater than or equal to zero at the end of each reporting period.

   b. If the actual quantity of fuel produced during a reporting period is greater than the quantity calculated using a. above, and all feedstocks in inventory and received by the production facility during the reporting period were included in the fuel pathway application, the excess fuel must be reported under a fuel pathway with the highest CI among all pathways certified for the fuel production facility.

2. Paragraph 1. above notwithstanding, a different allocation methodology may be used with the Executive Officer approval. The methodology must be submitted to the Executive Officer at the time of fuel pathway application and be included in the monitoring plan for verifier's review.

3. Facilities with multiple certified fuel pathways that do not use feedstock inventory accounting must include chemical analysis data supporting the calculated yield (i.e. the converted fraction of measured feedstock) in annual Fuel Pathway Reports. The producer or fuel reporting entity must use the yield calculated from the most recent prior analysis to determine the quantities of fuel to allocate to each FPC.

(D) *Exports.* If fuel reported in the LRT-CBTS is subsequently exported out of California, the export must be reported in the LRT-CBTS by the entity responsible for reporting export as described in subsection 95483(a).

1. *Reporting Fuel Blends.* When reporting export of fuel blends, the amount of each blendstock shall be reported in the LRT-CBTS. If the accurate blend percentage of each blendstock is not known then default blend percentage values provided on the LCFS ~~web site~~website shall be used for reporting the exports. Default blend percentage values are based on prior year average values.

2. *Substitute Pathways.* When an FPC is not available for reporting a fuel in the LRT-CBTS, a fuel reporting entity must use the Substitute pathway corresponding to its fuel type, pursuant to section 95488.9(d).

(2) *Specific Quarterly Reporting Parameters for Natural Gas (including CNG, LNG, and L-CNG).* For each fueling facility to which CNG, LNG, and L-CNG, is supplied as a transportation fuel:

(A) The quantity of fuel dispensed must be reported per FSE, as set forth in section 95483.2(b), with a certified FPC and with transaction type “NGV Fueling.” For CNG and L-CNG, the quantity of fuel dispensed (in Therms at Higher Heating Value (HHV)) per reporting period separately for all light/medium-duty vehicles (LDV & MDV), for heavy-duty vehicles with compression ignition engines (HDV-CIE), and for heavy-duty vehicles with spark ignition engines (HDV-SIE). For LNG, the volume of fuel dispensed (in gal) per reporting period separately for all LDV/MDV, for HDV-CIE, and for HDV-SIE.

(B) For Bio-CNG, Bio-LNG, and Bio-L-CNG: Biomethane production Company ID and Facility ID.

(C) The total quantity of fuel, summed across all FPCs, dispensed for transportation purpose through the FSE during the reporting period.

(D) When the vehicle application is unknown, for the purpose of reporting, a fueling event of less than 3,500 MJ (30 gasoline gallon equivalents) of fuel dispensed must be reported as NGV Fueling of LDV/MDV. A fueling event of 3,500 MJ or more must be reported as NGV Fueling of HDV.

(3) *Specific Quarterly Reporting Parameters for Electricity used as a Transportation Fuel*.

(A) *For Non-Metered Residential EV charging*.

1. Within the first 45 days after the end of the quarter, the EDU must provide the Executive Officer Daily Average EV Electricity Use data for the calculation of credits for non-metered charging from the prior quarter. The Executive Officer shall use the method set forth in subsection 95486.1(c)(1), to calculate any credits generated for the quarter and place them into the EDU's LRT-CBTS account; and

~~2. The LSE must use all credit proceeds to benefit current or future EV drivers in California;~~

~~3. The LSE must educate the public and customers on the benefits of EV transportation (including environmental benefits and costs of EV charging, or total cost of ownership, as compared to gasoline);~~

~~4. The LSE must provide rate options that encourage off-peak charging and minimize adverse impacts to the electrical grid;~~

~~5. The LSE must include, in the Annual Compliance Report, the following supplemental information: an itemized summary of efforts to meet requirements 1. through 3. above and costs associated with meeting the requirements. Investor-owned utilities must also provide an unredacted copy of the annual implementation report required under Order 4 of Public Utilities Commission of California (PUC) Decision 14-12-083, or any successor PUC Decisions.~~

~~6. For claiming incremental credit for non-metered residential charging, the LSE must be able to provide, upon request of the Executive Officer: the VIN for each electric vehicle claimed and evidence of EV vehicle registration and low-carbon electricity supply at the same location.~~

~~7. A non-LSE credit generator must use credit proceeds to benefit EV drivers and their customers, and educate them about the benefits of EV transportation (including environmental benefits and costs of EV charging, or total cost of ownership, as compared to gasoline). The credit generator must include, in their Annual Compliance Report, an itemized summary of efforts and costs associated with meeting these requirements.~~

(B) *For Metered Residential EV charging*.

1. For generating base credits, the quantity of electricity (in kWh) used for residential EV charging must be reported per FSE, as set forth in section 95483.2(b), using the Lookup Table pathway for California Average Grid Electricity and with transaction type "EV Charging - Grid."

2. For generating incremental credit for low-CI electricity, the quantity of electricity (in kWh) used for residential EV charging must be reported per FSE, as set forth in section 95483.2(b), using a certified FPC and with transaction type "EV Charging - Non-Grid", and the following requirements must be met:

   a. The reporting entity must be able to provide to the Executive Officer records, upon request, demonstrating that the low-CI electricity is supplied (including through book-and-claim accounting) to the same residences where the EV charging is taking place and during the period for which incremental credits are generated, and that any renewable energy certificates associated with the low-CI electricity were retired in the WREGIS for the purpose of LCFS credit generation;

   b. Records must be provided to the Executive Officer, upon request, demonstrating an EV is owned or leased by an individual dwelling at the claimed residence; and

   c. Only a single entity can generate incremental credits using a low-CI pathway for the same FSE. If two or more entities report for the same FSE to generate incremental credits, no incremental credits will be issued for that FSE.

3. For generating incremental credit for smart charging, the quantity of electricity (in kWh) used for residential EV charging must be reported per FSE, as set forth in section 95483.2(b), using the smart charging pathway CI values and with transaction type "EV Charging - Smart Charging", and the following requirements must be met:

   a. The quantity of electricity used for each hourly window, as per Table 7-2 in section 95488.5(f), must be reported;

b. The reporting entity must be able to provide documentation showing the quantity of electricity used during a reporting period broken down by hourly windows upon request by the Executive Officer;

c. Only a single entity can generate incremental credits for smart charging for the same FSE; and

d. Records must be provided to the Executive Officer, upon request, demonstrating the FSE was enrolled in a Time-of-Use rate plan during the reporting period, if offered by the LSE.

(C) *For Non-Residential EV Charging*.

1. For generating credit using grid electricity, the quantity of electricity (in kWh) used for EV charging must be reported per FSE, as set forth in section 95483.2(b), using the Lookup Table pathway for California Average Grid Electricity and with transaction type "EV Charging - Grid."

2. For generating credit using any low-CI electricity, the quantity of electricity (in kWh) used for EV charging must be reported per FSE, as set forth in section 95483.2(b), using a certified FPC and with transaction type "EV Charging - Non-Grid", and the following requirements must be met:

a. The reporting entity must be able to provide to the Executive Officer records, upon request, demonstrating that the low-CI electricity is supplied (including through book-and-claim accounting) to the FSE during the period for which incremental credits are generated, and that any renewable energy certificates associated with the low-CI electricity were retired in the WREGIS for the purpose of LCFS credit generation.

3. For generating credit for smart charging, the quantity of electricity (in kWh) used for EV charging must be reported per FSE, as set forth in section 95483.2(b), using the smart charging pathway CI values and with transaction type "EV Charging - Smart Charging", and the following requirements must be met:

a. The quantity of electricity used for each hourly window, as per Table 7-2 in section 95488.5(f), must be reported;

b. The reporting entity must be able to provide documentation showing the quantity of electricity used during a reporting period broken down by hourly windows upon request by the Executive Officer; and

c. Records must be provided to the Executive Officer, upon request, demonstrating the FSE was enrolled in a Time-of-Use rate plan during the reporting period, if offered by the LSE.

(D) *For Fixed Guideway Systems.* The quantity of electricity used for transit propulsion (in kWh) must be reported per FSE with a certified FPC and with transaction type "Fixed Guideway Electricity Fueling." FSE ID is assigned by system during the registration as specified in section 95843.2(b)(8).

(E) *For Electric Forklifts.* The quantity of electricity used (in kWh) dispensed must be reported per FSE, as set forth in section 95483.2(b)(8), with a certified FPC and with transaction type "~~EV Forklifts~~Forklift Electricity Fueling." ~~The quantity of electricity used in electric forklifts may be determined as follows:~~

~~1. Quantity of electricity used during a reporting period, as measured per FSE, as set forth in section 95483.2(b), and with transaction type "Forklift Electricity Fueling", in the case of an electric forklift fleet owner or its designee generating credits; or~~

~~2. Quantity of electricity estimated using CARB approved methodology. The reporting entity must provide the number of electric forklifts in the fleet for generating credits; or~~

~~3. When electric forklift credits are claimed by an EDU, CARB staff will calculate the quantity of electricity supplied to electric forklifts in the EDUs service territory during a reporting period for the generation of credits. This reporting parameter is exempt from the quarterly reporting deadlines set forth in section 95491(b).~~

(F) *For Electric Transport Refrigeration Unit.* The quantity of electricity (in kWh) dispensed must be reported per FSE, as set forth in section 95483.2(b), with a certified FPC and with transaction type "eTRU Fueling."

(G) *Electric Cargo Handling Equipment.* The quantity of electricity (in kWh) dispensed must be reported per FSE, as set forth in section

95483.2(b), with a certified FPC and with transaction type "eCHE Fueling."

(H) *Electric Power for Ocean-going Vessel.* The quantity of electricity (in kWh) dispensed must be reported per FSE, as set forth in section 95483.2(b), with a certified FPC and with transaction type "eOGV Fueling."

(I) *Other Electric Transportation Applications.* The quantity of electricity (in kWh) dispensed must be reported per FSE with a certified FPC and with transaction type made available by Executive Officer pursuant to section 95488.7.

(4) *Specific Quarterly Reporting Parameters for Hydrogen Used as a Transportation Fuel*.

(A) The quantity (in kg) of hydrogen fuel dispensed per FSE, as set forth in section 95483.2(b), with a certified FPC and with transaction type "FCV Fueling" by vehicle weight category: LDV & MDV and HDV.

(B) For hydrogen fuel cell forklifts, the amount of hydrogen fuel dispensed (in kg) per FSE with a certified FPC and with transaction type "Forklift Hydrogen Fueling."

(C) Production Company ID and Facility ID.

(D) For hydrogen reported with a pathway that utilizes book-and-claim accounting for electricity as specified in section 95488.8(i)(1)(B) the reporting entity must be able to provide to the Executive Officer records, upon request, demonstrating that the low-CI electricity is supplied (including through book-and-claim accounting) to the FSE during the period, and that any renewable energy certificates associated with the low-CI electricity were transferred from the fuel pathway holder to the reporting entity and retired for the purpose of LCFS credit generation.

~~(D)~~(E) For hydrogen reported with a pathway that claims carbon intensity reductions for shifts in time of electricity use for electrolytic hydrogen production, the quantity of electricity (in kWh) used to produce hydrogen for each hourly window must be reported with transaction type "FCV Fueling--Smart Electrolysis" and the following requirements must be met:

a. The quantity of electricity used for each hourly window, as per Table 7-2 in section 95488.5(f), must be reported; and

b. The reporting entity must provide documentation showing the quantity of electricity used during a reporting period broken down by hourly windows, upon request by the Executive Officer.

(5) *Specific Quarterly Reporting Parameters for Propane*.

(A) The quantity (in gal) of propane dispensed per FSE, as set forth in section 95483.2(b), with a certified FPC and with transaction type "Propane Fueling."

(B) For renewable propane, the Production Company ID and Facility ID.

(e) *Reporting Requirements for Annual Compliance Reports.* A fuel reporting entity and project operators must submit an annual compliance report that aggregates the quarterly fuel transactions reports and provides the additional information set forth below:

(1) LRT-CBTS generates an annual summary, for each fuel reporting entity and project operator, that includes the following:

(A) The total credits and deficits generated by the fuel reporting entity and project operator in the compliance period, calculated in the LRT-CBTS as per sections 95486.1 and 95489;

(B) Any credits carried over from the previous compliance period;

(C) Any deficits carried over from the previous compliance period;

(D) The total credits acquired from another entity;

(E) The total credits sold or otherwise transferred;

(F) The total credits retired within the LCFS to meet compliance obligation per section 95485; and

(G) Total credits acquired from or pledged for sale into the CCM, if applicable;

(H) Total credits purchased as carryback credits; and

(I) Any credits on administrative hold.

(2) A producer of CARBOB, gasoline, or diesel fuel must report, for each of its refineries, the MCON or other crude oil name designation, amount (in gal), and Country (or State) of origin for each crude supplied to the refinery during the annual compliance period.

(3) All pending credit transfers initiated during a compliance period must be completed prior to submittal of the annual compliance report, if possible. If there is still a pending outgoing credit transfer, the credits will be taken from the account of the Seller that initiated the transfer and the annual compliance report will reflect the adjusted credit balance. If there is a pending incoming credit transfer, the Buyer's annual report will not reflect the balance until the transfer is completed. Upon completion, the annual compliance report must be reopened and resubmitted with the adjusted credit balance.

(4) *Attestations Regarding Environmental Attributes for Biomethane.* Entities reporting bio-CNG, bio-LNG, and bio-L-CNG must submit the environmental attribute attestation pursuant to section 95488.8(i)(2)(C) along with the annual compliance report in the LRT-CBTS.

(5) *Uses of Electricity Credit Proceeds*. Entities generating credits from electricity must use all credit proceeds to further transportation electrification efforts in California. The credit generator must include, in their Annual Compliance Report, an itemized summary of efforts and costs associated with meeting this requirement.

(A) Additional Reporting Requirements for Entities Generating Non-metered Base Credits.

1. *Reporting on Clean Fuel Reward Program Implementation*. By April 30 the administrator of the Clean Fuel Reward program funded by LCFS credit proceeds shall submit a report to the Executive Officer describing the disposition of LCFS Clean Fuel Reward program funds from the previous calendar year. This report must include:

a. The monetary value of LCFS credit proceeds received by the Clean Fuel Reward program; and

b. A summary, detailed list, and explanation of administrative costs, including start-up costs, utility overhead costs, and costs for program-related marketing, education, and outreach activities.

2. *Holdback Equity Reporting Requirements*. EDUs must include a discussion on how their portfolio of holdback credit equity projects is consistent with the findings and recommendations of the SB 350 Low-Income Barriers Study, Part B report prepared by CARB (rev. Feb. 2018), incorporated herein by reference. This discussion must include, as applicable, a description of how the projects: support increased access to clean transportation and

mobility options; consider, and to the extent feasible, either complement or build upon existing CARB, other State, or local incentive projects to diversify and maximize benefits from statewide investments; demonstrate partnership and support from local community-based organizations; and meet community-identified clean transportation needs.

3. Investor-owned utilities must also provide an unredacted copy of the annual implementation report required under Order 4 of Public Utilities Commission of California (PUC) Decision 1412-083, or any successor PUC Decisions.

(f) *Significant Figures.* A regulated entity must report the following quantities as specified below:

(1) Carbon intensity, expressed to the same number of significant figures as shown in Tables 7-1, and 9;

(2) Credits or deficits, expressed to the nearest whole metric ton CO_2 equivalent;

(3) Fuel amounts in units specified in sections 95491(d) and (e), expressed to the nearest whole unit applicable for that quantity; and

(4) Any other quantity must be expressed to the nearest whole unit applicable for that quantity.

(g) A fuel reporting entity must maintain a non-negative value for Total Obligated Amount and Total Amount, as defined in section 95481, for each FPC as summed across all quarterly data in the LRT-CBTS.

(h) *Correcting a Previously Submitted Report.* Upon discovery of an error, a fuel reporting entity may request to have previously submitted quarterly reports for the current compliance periods reopened for corrective edits and resubmittal by submitting a Correction Request Form online in the LRT-CBTS. The fuel reporting entity is required to provide justification for the report corrections and indicate the specific corrections to be made to the report. Pursuant to section 95486(a)(2), no credits may be claimed, and no deficits may be eliminated, retroactively for a quarter for which the quarterly reporting deadline has passed. Each submitted request is subject to Executive Officer review and approval. Permission to correct a report does not preclude enforcement based on misreporting.

Table 11. Summary Checklist of Quarterly and Annual Reporting Requirements.

Parameters to Report	***Gasoline ~~&~~, Diesel & Fossil Jet Fuel Blends***	***Natural Gas & Propane***	***Electricity***	***Hydrogen***	***Neat Ethanol, Biomass-Based Diesel Fuels, Alternative Jet Fuel & Other Alternative Fuels***
For Quarterly Reporting					
Organization FEIN	x	x	x	x	x
Reporting Period (year & quarter)	x	x	x	x	x
Fuel Pathway Code	x	x	x	x	x
Transaction Type	x	x	x	x	x
* Transaction Date	x	x	x	x	x
Business Partner (if applicable)	x	x			x
Production Company ID and Facility ID	x**	x**	n/a	x	x**
Fueling Supply Equipment ID	n/a	x	x	x	n/a
Vehicle Identifier (if applicable)	n/a	n/a	x	n/a	n/a
Aggregated Transaction Indicator (T/F)	x	x	n/a	x	x
Fuel Application	x	x	x	x	x
Amount of each gasoline and diesel blendstock	x	n/a	n/a	n/a	n/a
Amount of each fuel used as gasoline or diesel replacement	n/a	x	x	x	x

Parameters to Report	***Gasoline ~~&~~, Diesel & Fossil Jet Fuel Blends***	***Natural Gas & Propane***	***Electricity***	***Hydrogen***	***Neat Ethanol, Biomass-Based Diesel Fuels, Alternative Jet Fuel & Other Alternative Fuels***
Amount of each fuel used as a fossil jet fuel replacement	n/a	n/a	n/a	n/a	x
MCON or other crude oil name designation, volume (in gal), and country (or state) of origin for each crude supplied to the refinery	x	n/a	n/a	n/a	n/a
ZEV Fueling Infrastructure Pathway Costs and Revenues (if applicable)	n/a	n/a	x	x	n/a
For Annual Reporting (in addition to the items above)					
***Credits and Deficits generated per year (MT)	x	x	x	x	x
***Credits/deficits carried over from the previous year (MT), if any	x	x	x	x	x
***Credits acquired from another entity (MT), if any	x	x	x	x	x
***Credits sold to another entity (MT), if any	x	x	x	x	x
***Credits pledged for sale into CCM (MT), if any	x	x	x	x	x

Parameters to Report	***Gasoline ~~&~~, Diesel & Fossil Jet Fuel Blends***	***Natural Gas & Propane***	***Electricity***	***Hydrogen***	***Neat Ethanol, Biomass-Based Diesel Fuels, Alternative Jet Fuel & Other Alternative Fuels***
***Credits retired within LCFS (MT) to meet compliance obligation, if any	x	x	x	x	x
MCON or other crude oil name designation, volume (in gal), and country (or state) of origin for each crude supplied to the refinery	x	n/a	n/a	n/a	n/a

* Same as Title Transfer Date; For Aggregated Transactions enter the last day of the reporting period.
** Does not apply to CARBOB, Diesel Fuel, Fossil Propane, or Fossil NG.
*** Value will be calculated, stored and displayed in the LRT-CBTS.

Table 12. Annual Compliance Calendar.

February 14	Upload all Q4 fuel transactions data in the LRT-CBTS and begin any needed reconciliation with business partners; Electrical Distribution Utility (EDU) that has opted into LCFS provide the data relevant to the calculation of base credits for non-metered EV charging for the prior quarter
March 31	Submit final Q4 fuel transactions report; Submit Q4 Crude Oil Reports (MCON Reports)
March 31	Annual Fuel Pathway Reports and Annual Low-Complexity/Low-Energy-Use Refinery (LC/LEU) Reports are due to the Executive Officer
First Monday of April	Call for credits to be pledged into the Credit Clearance Market (CCM); the new maximum price for credits is published
April 30	Submit final Annual Compliance Report for preceding year; demonstrate compliance; voluntary pledge of credits for sale into CCM

April 30	Compliance Plan Implementation Report due if entity has an Approved Compliance Plan
April 30	Annual Crude Oil Reports (Annual MCON Reports~~)~~), Annual Low-Complexity/Low-Energy-Use Refinery (LC/LEU) Reports, and Project Reports electing annual verification are due to the Executive Officer
May 15	Upload all Q1 fuel transactions data in the LRT-CBTS and begin any needed reconciliation with business partners; EDU that has opted into LCFS provide the data relevant to the calculation of base credits for non-metered EV charging for the prior quarter
May 15	Executive Officer announces whether CCM will occur
June 1	Executive Officer posts list of CCM buyers and sellers
June 1	CCM for prior compliance year, if one occurs, opens and remains in effect until it closes on August 30~~th~~
June 1	New maximum credit price for all LCFS credit transactions goes into effect
June 30	Submit final Q1 fuel transactions report; Submit Q1 Crude Oil Reports (MCON Reports)
August 14	Upload all Q2 fuel transactions data in the LRT-CBTS and begin any needed reconciliation with business partners; EDU that has opted into LCFS provide the data relevant to the calculation of base credits for non-metered EV charging for the prior quarter
August 30	CCM for prior compliance year closes
August 31	Entities that bought and sold credits in the CCM submit amended Annual Compliance Report
August 31	Entities that participated in two consecutive CCMs submit a Compliance Plan
August 31	Verification Statements for Annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, Project Reports electing annual verification, Annual LC/LEU Reports, and ~~Quarterly and~~ Annual Crude Oil Reports (MCON Reports) are due to the Executive Officer
September 30	Submit final Q2 fuel transactions report; Submit Q2 Crude Oil Reports (MCON Reports)

November 14	Upload all Q3 fuel transactions data in the LRT-CBTS and begin any needed reconciliation with business partners; EDU that has opted into LCFS provide the data relevant to the calculation of base credits for non-metered EV charging for the prior quarter
December 31	Submit final Q3 fuel transactions report; Submit Q3 Crude Oil Reports (MCON Reports)

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95491.1. Recordkeeping and Auditing.

(a) *Record Retention.* Any record required to be maintained under this subarticle shall be retained for ten years. All data and calculations submitted by a regulated entity for demonstrating compliance, or generating credits or deficits are subject to inspection by the Executive Officer or a verification body accredited by the Executive Officer pursuant to section 95502, and must be made available within ~~20~~14 days upon request of the Executive Officer.

(1) *Record Retention for Fuel Reporting Entities.* Fuel reporting entities must maintain all records and calculations relied upon for data reported in the LRT-CBTS. These records include, but are not limited to:

(A) Product transfer documents;

(B) Copies of all data reports submitted to the Executive Officer;

(C) Records related to each fuel transaction;

(D) Records used for each credit transaction;

(E) Records related to FSE registration, including but not limited to copies of monthly utility bills, Bills of Lading, Division of Measurement Standards' certificates, and any other document used as a proof at the time of FSE registration pursuant to this subarticle;

(F) Chain of custody evidence for produced fuel imported into California;

(G) Attestations regarding environmental attributes associated with book-and-claim accounting for biomethane pursuant to 95488.8(i)(2)(~~C~~E); and

(H) Records used for compliance or credit and deficit calculations.

(2) *Record Retention for Fuel Pathway Holders and Applicants.* Fuel pathway holders and applicants must maintain all records relied upon in producing fuel pathway applications and annual Fuel Pathway Reports. The retained documents, including CI input source data and supplemental documentation, must be sufficient to allow for verification of each CI calculation. These records include but are not limited to:

(A) The quantity of fuel produced and subsequently sold in California under the certified fuel pathway. Sales invoices, contracts, and bills of lading for those fuel sales shall be retained.

(B) The quantity of feedstocks purchased to produce the fuel specified in subsection (A) above. Invoices from the sellers and purchase contracts shall be retained. Records to support material balance and energy balance calculations for facilities processing multiple feedstocks.

(C) The quantity of all forms of energy consumed to produce the fuel covered in subsection (A) above. All invoices for the purchase of process fuel, and all receipts for the sale of the fuel pathway applicant's finished fuel shall be maintained.

(D) Copies of the federal RFS Third Party Engineering Review Report, if required pursuant to 40 CFR 80.1450.

(E) The quantity of all products co-produced with the fuel covered by certified LCFS pathway. Copies of invoices, contracts, and bills of lading covering those sales shall be retained. In addition, copies of the federal RFS Fuel Producer Co-products Report shall be retained, if applicable. If the amount of co-product produced exceeds the amount sold by five percent or more, full documentation of the fate of the unsold fractions shall be maintained.

(F) Evidence demonstrating chain of custody from the point of origin along the supply chain to the fuel production facility is required for any feedstock defined as a specified source feedstock pursuant to section 95488.8(g). A copy of the federal RFS separated food waste plan required pursuant to 40 CFR 80.1450(b)(1)(vii)(B), if applicable.

(G) Any additional records that the Executive Officer requests during pathway certification, and records that demonstrate compliance with all special limitations and operating conditions issued at the time of certification.

(H) Attestations regarding environmental attributes associated with book-and-claim accounting for biomethane pursuant to 95488.8(i)(2)(~~C~~E).

(3) *Record Retention for Verification Bodies.* The verification body providing verification services pursuant to this subarticle must retain the following:

(A) The sampling plan in paper, electronic, or other format for a period of no less than ten years following the submission of each validation or verification statement. The sampling plan must be made available to the Executive Officer upon request.

(B) All material received, reviewed, or generated to render a validation or verification statement for an entity required to validate and verify under LCFS. The documentation must allow for a transparent review of how a verification reached its conclusion in the validation or verification statement, including independent review.

(b) *Documenting Fuel Transfers Reported in the LRT-CBTS.* A product transfer document provided by a fuel reporting entity pursuant to section 95483(a) must prominently state the information specified below.

(1) For transfers where an LCFS obligation to act as a credit or deficit generator is being passed to the recipient:

(A) Transferor Company Name, Address and Contact Information;

(B) Recipient Company Name, Address and Contact Information;

(C) Transaction Date: Date of Title Transfer for Fuel;

(D) Fuel Pathway Code (FPC) and Carbon Intensity (CI);

(E) Fuel Quantity and Units;

(F) A statement identifying whether the LCFS obligation to act as a credit or deficit generator is passed to the recipient; and

(G) Fuel Production Company ID and Facility ID as registered with RFS program or LCFS program. This does not apply to CARBOB, Diesel Fuel or Fossil NG.

(2) For transfers where the LCFS obligation to act as a credit or deficit generator was retained by the transferor, the following is to be provided to the recipient and passed along to any subsequent owner or supplier:

(A) All information identified in subsection 95491.1(b)(1). above as items (A) through (G);

(B) The following notice reading as follows:

"This transportation fuel has been reported to the CARB LCFS Program by <*Insert name of Fuel Reporting Entity holding LCFS obligation to act as a credit or deficit generator*> for intended use in California. If you export this fuel from California you must report to the CARB LCFS Program (www.arb.ca.gov/lcfsrt). Contact the CARB LCFS Administrator for assistance with reporting exported amounts (lrtadmin@arb.ca.gov)."

(c) *Monitoring Plan for Entities Required to Validate or Verify.* Each entity responsible for obtaining a validation or verification statement under this subarticle must complete and retain for review by a verifier, or the Executive Officer, a written Monitoring Plan. Entities also reporting pursuant to MRR may use a single monitoring plan for both programs, so long as all of the following elements are included and clearly identified:

(1) The monitoring plan must contain the following general items and associated references to more detailed information:

(A) Information to allow CARB and the verification team to develop a general understanding of boundaries and operations relevant to the entity, facility, or project, including participation in other markets and other third-party audit programs;

(B) Reference to management policies or practices applicable to reporting pursuant to this subarticle, including recordkeeping;

(C) Explanation of the processes and methods used to collect necessary data for reporting pursuant to this subarticle, including identification of changes made after January 1, 2019;

(D) Explanations and queries of source data to compile summary reports of intermediate and final data necessary for reporting pursuant to this subarticle;

(E) Reference to one or more simplified block diagrams that provide a clear visual representation of the relative locations and positions of measurement devices and sampling locations, as applicable, required for calculating reported data (e.g., temperature, total pressure, LHV or HHV, fuel consumption); the diagram(s) must include storage tanks for raw material, intermediate products, and finished products, fuel sources, combustion units, and production processes, as applicable;

(F) Clear identification of all measurement devices supplying data necessary for reporting pursuant to this subarticle, including identification of low flow cutoffs as applicable, with descriptions of how data from measurement devices are incorporated into the submitted report;

(G) Descriptions of measurement devices used to report LCFS data and how acceptable accuracy is demonstrated, e.g., installation, maintenance, and calibration method and frequency for internal meters or how the criteria in MRR section 95103(k)(7) are met to demonstrate meters are financial transaction meters such that the accuracy is acceptable; this provision does not apply to data reported in the LRT-CBTS for generating credits for EV charging;

(H) Description of the procedures and methods that are used for quality assurance, maintenance, and repair of all continuous monitoring systems, flow meters, and other instrumentation used to provide data for LCFS reports;

(I) Original equipment manufacturer (OEM) documentation or other documentation that identifies instrument accuracy and required maintenance and calibration requirements for all measurement devices used to collect necessary data for reporting pursuant to this subarticle;

(J) The dates of measurement device calibration or inspection, and the dates of the next required calibration or inspection;

(K) Requests for postponement of calibrations or inspections of internal meters and subsequent approvals by the Executive Officer. The entity must demonstrate that the accuracy of the measured data will be maintained pursuant to the measurement accuracy requirements of 95488.8(j);

(L) A listing of the equation(s) used to calculate flows in mass, volume, or energy units of measurement, and equations from which any non-measured parameters are obtained, including meter software, and a description of the calculation of weighted average transport distance;

(M) Identification of job titles and training practices for key personnel involved in LCFS data acquisition, monitoring, reporting, and report attestation, including reference to documented training procedures and training materials;

(N) Records of corrective and subsequent preventative actions taken to address verifier and CARB findings of past nonconformance and material misstatements;

(O) Log of modifications to fuel pathway report conducted after attestation in response to review by third-party verifier or CARB staff;

(P) Written description of an internal audit program that includes data report review and documents ongoing efforts to improve the entity's LCFS reporting practices and procedures, if such an internal audit program exists; and

(Q) Methodology used to allocate the produced fuel quantity to each certified FPC.

(2) The monitoring plan must also include the following elements specific to fuel pathway carbon intensity calculations and produced quantities of fuels per FPC, as applicable:

(A) Explanation of the processes and methods used to collect necessary data for fuel pathway application and Fuel Pathway Reports and all site-specific CA-GREET~~3~~4.0 inputs, as well as references to source data;

(B) Description of steps taken and calculations made to aggregate data into reporting categories, for example aggregation of quarterly fuel transactions per FPC;

(C) Methodology for assigning fuel volumes by FPC, if not using a method prescribed/suggested by CARB. If using a CARB suggested methodology, the methodology should be referenced;

(D) Methodologies for testing conformance to specifications for feedstocks and produced fuels, particularly describing physical testing standards and processes;

(E) Description of procedure taken to ensure measurement devices are performing in accordance with the measurement accuracy requirements of 95488.8(j);

(F) Methodology for monitoring and calculating weighted average feedstock transport distance and modes, including the specific documentation records that will be collected and retained on an ongoing basis;

(G) Methodology for monitoring and calculating fuel transport distance and modes, including the specific documentation records that will be collected and retained on an ongoing basis;

(H) References to contracts and accounting records that confirm fuel /quantities were delivered into California for transportation use in CI determination, and confirm feedstock and finished fuel transportation distance;

(I) All documentation required pursuant to 95488.8(g)(1)(B) for specified source feedstocks, defined in 95488.8(g)(1)(A);

(3) The monitoring plan must also include the following elements specific to quarterly fuel transactions reports for importers, exporters and producers of alternative fuels, gasoline and diesel, as well as quarterly reports of crude oil information, as applicable:

(A) Documentation that can be used to justify transaction types reported for fuel in the LRT-CBTS must be referenced in the monitoring plan. This can pertain to the production amount, sale/purchase agreements and final fuel dispensing records.

(d) *Verification Outcomes.* Each entity responsible for obtaining a validation or verification statement under this subarticle must obtain third-party verification services from a verification body that meets the requirements specified in section 95502. A positive or qualified positive verification statement for the previous calendar year must be submitted to the Executive Officer by the verification body by August 31 in order to maintain a valid fuel pathway code for use in reporting fuel transactions for credit generation. An adverse transactions verification statement would result in Executive Officer investigation and possible enforcement action.

(e) *Access to Records.* Pursuant to H&S section 41510, the Executive Officer has the right of entry to any premises used, leased, or controlled by a regulated entity in order to inspect and copy records relevant to the determination of compliance. Scheduling of access shall be arranged in advance where feasible and must not unreasonably disturb normal operations, provided, however that access shall not be unreasonably delayed.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95492. Enforcement Protocols.

* * * *

§ 95493. Jurisdiction.

* * * *

§ 95494. Violations.

* * * *

§ 95495. Authority to Suspend, Revoke, Modify, or Invalidate.

(a) If the Executive Officer determines that any basis for invalidation set forth in subsection (b)(1) below occurred, in addition to taking any enforcement action, he or she may: suspend, restrict, modify, or revoke an LRT-CBTS account; modify or delete a Certified CI; restrict, suspend, or invalidate credits; or recalculate the deficits in an LRT-CBTS account. For purposes of this section, “Certified CI” includes any determination relating to carbon intensity made pursuant to sections 95488 through 95488.10, or relating to a credit generating activity approved under section 95489.

(b) *Determination that a Credit, Deficit Calculation, or Certified CI is Invalid*.

(1) *Basis for Invalidating.* The Executive Officer may modify or delete a Certified CI and invalidate credits or recalculate deficits based on any of the following:

(A) Any of the information used to generate or support the Certified CI was incorrect for reasons including the omission of material information or changes to the process following submission;

(B) Any material information submitted in connection with any Certified CI or credit transaction was incorrect;

(C) Fuel reported under a given pathway was produced or transported in a manner that varies in any way from the methods set forth in any corresponding pathway application documents submitted pursuant to sections 95488 through 95488.10;

(D) Fuel transaction or other data reported into LRT-CBTS and used in calculating credits and deficits was incorrect or omitted material information;

(E) Credits or deficits were generated or transferred in violation of any provision of this subarticle or in violation of other laws, statutes or regulations;

(F) A person obligated to provide records under this subarticle refused to provide such records or failed to produce them within the required time; and

(G) The sequestered CO_2 associated with credits generated for verified greenhouse gas emission reductions by a CCS project was released or otherwise leaked to the atmosphere.

(H) Credits were generated in violation of section 95491.2(b)(2)(C).

~~(H)~~(I) For purposes of this section, "material information" means:

1. Information that would affect by any amount the Executive Officer's determination of a carbon intensity score, expressed on a gCO_2e/MJ basis to two decimal places, or

2. Information that would affect by any whole integer the number of credits or deficits generated under sections 95486, 95486.1, 95486.2, 95489, or resulting from any transaction or other activity reported in the LRT-CBTS.

(2) *Notice.* Upon making an initial determination that a credit (other than a provisional credit), deficit calculation, or Certified CI (other than a provisionally-certified CI) may be subject to modification, deletion, recalculation, or invalidation under subsection (b)(1), above, the Executive Officer will notify all potentially affected parties, including those who hold or generate credits or deficits based on a Certified CI that may be invalid, and may notify any linked program. The notice shall state the reason for the initial determination, and may be distributed using the LRT CBTS. Any party receiving such notice may submit, within ~~20~~14 days, any information that it wants the Executive Officer to consider. The Executive Officer may request information or documentation from any party likely to have information or records relevant to the validity of a credit, deficit calculation, or Certified CI. Within ~~20~~14 days of any such request, a regulated entity shall make records and personnel available to assist the Executive Officer in determining the validity of the credit, deficit calculation, or Certified CI.

(3) *Interim Account Suspension.* When the Executive Officer makes an initial determination pursuant to the preceding subsection, the Executive Officer may immediately take steps to suspend an account or a Certified CI as needed to prevent additional accrual of credits or deficits under the Certified CI and to prevent transfer of potentially invalid credits or deficits. Suspension of an account may include locking an account within the LRT-CBTS to prevent credit transfers or report alteration.

(4) *Final Determination.* Within ~~50~~30 days after making an initial determination under sections 95495(b)(1) and (2), above, the Executive Officer shall make a final determination based on available information whether, in his or her judgment, any of the bases listed in subsection (b)(1) exists, and notify affected parties and any linked program. If the final determination invalidates credits or deficit calculations, the corresponding credits and deficits will be added to or subtracted from the appropriate LRT-CBTS accounts. Where such action creates a deficit in a past compliance period, the deficit holder has 60 days from the date of the final determination to

purchase sufficient credits to eliminate the entire deficit. A return to compliance does not preclude further enforcement actions.

(5) *Adjustment of Invalidated Credits or Miscalculated Deficits.* The Executive Officer will seek the following options to address any invalid credits or miscalculated deficits in the program:

(A) First, the Executive Officer may remove the invalid credits from, or add miscalculated deficits to, the account of the credit or deficit generator, or other entity deemed responsible for the invalidation or miscalculation in the final determination pursuant to section 95486. The entity is responsible for returning its account to compliance.

(B) Next, the Executive Officer may choose to retire credits from the Buffer Account to address invalidated credits or uncovered deficits.

(C) After exercising options in subsection (A) and (B) above, the Executive Officer may remove remaining invalid credits from an entity's account that holds or previously held invalid credits. The entity is responsible for returning its account to compliance.

(D) The Executive Officer will not remove invalid credits from entities that purchased those credits in the Credit Clearance Market, pursuant to section 95485(c).

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511, and 43018 Health and Safety Code; 42 U.S.C. section 7545, and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95496. [Reserved].

§ 95497. Severability.

* * * *

§ 95500. Requirements for Validation of Fuel Pathway Applications; and Verification of Annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, Crude Oil Quarterly and Annual Volumes Reports, Project Reports, and Low -Complexity/Low-Energy-Use Refinery Reports.

(a) *Validation of Fuel Pathway Applications (CIs).*

(1) *Applicability.* The following entities must obtain the services of a verification body accredited by the Executive Officer for purposes of

conducting verification services, including required site visit(s), for each fuel pathway application submitted under this subarticle.

(A) Fuel pathway applicants supplying site-specific CI data for the fuel pathway application, as specified in sections 95488.5 through 95488.8.

(B) Specified source feedstock suppliers and other entities with site-specific CI data who apply for separate Executive Officer recognition as a joint applicant and elect to be responsible for separate validation and verification as specified in section 95488(b).

(b) *Verification of Annual Fuel Pathway Report (CIs)*.

(1) *Applicability.* The following entities must obtain the services of a verification body accredited by the Executive Officer for purposes of conducting verification services, including required site visit(s), for each Fuel Pathway Report submitted under this subarticle.

(A) Holders of certified fuel pathways who supplied site-specific CI data for pathway certification and are required to update site-specific CI data on an annual basis, as specified in this subarticle, are responsible for annual verification of their Fuel Pathway Report.

(B) Specified source feedstock suppliers and other entities with site-specific CI data who apply for separate Executive Officer recognition as a joint applicant and elect to be responsible for separate validation and verification as specified in section 95488(b).

(2) *Verification Schedule.* Entities required to contract for verification of Fuel Pathway Reports (CI) must ensure a fuel pathway verification statement for each Fuel Pathway Report is submitted to the Executive Officer according to the following schedule.

(A) *Annual Verification.* Verification statements are due to the Executive Officer by August 31 of the year the annual Fuel Pathway Report is submitted, beginning in 2021 for 2020 data, unless eligible to defer verification, as specified in section 95500(b)(2)(B).

(B) *Deferred Verification.* Fuel pathway holders producing alternative fuels may defer verification of their annual Fuel Pathway Reports for each production facility up to two years if the quantity of fuel produced at the production facility and reported by any entity does not result in 6,000 or more credits and also does not result in 6,000 or more deficits generated in LRT-CBTS during the prior calendar year and does not include a fuel pathway with biomethane or hydrogen supplied using book-and-claim accounting pursuant to section 95488.8(i)(2). Fuel pathway holders classified as joint applicants are not eligible to defer verification.

The verification body must submit fuel pathway verification statements to the Executive Officer for all prior unverified reports on or before August 31 of the year verification is required or conducted for the production facility.

(C) Verification services may not begin until the entity required to contract for verification services attests that the data submitted to the Executive Officer is true, complete, and accurate by certifying under penalty of perjury under the laws of the State of California.

"Quarterly review" for purposes of this subarticle means a review process conducted by the verification team after quarterly data is submitted and before annual data is submitted and verified.

Quarterly review does not supersede the requirements for the verification team to consider all quarterly data submitted during annual verification. Quarterly review is optional for annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, and Crude Oil Quarterly and Annual Volumes Reports. Quarterly review must conform to the requirements for verification services in section 95501. A verification statement and verification report are not submitted after quarterly review.

Quarterly review of operational CI data may only be included as part of annual verification services if the fuel pathway holder submits quarterly data to the Executive Officer. Quarterly review may only be conducted after the fuel pathway holder submits the report and attests that the statements and information submitted are true, accurate, and complete.

(c) *Verification of Quarterly Fuel Transactions Reports*.

(1) *Applicability.* Entities submitting Quarterly Fuel Transactions Reports under this subarticle that include the following transaction types must obtain the services of a verification body accredited by the Executive Officer for purposes of conducting verification services, including required site visit(s). The scope of verification services would be limited to the following transaction types, including associated corrections submitted in annual reports under this subarticle.

(A) For all liquid fuels:

1. Production in California;

2. Production for Import;

3. Import;

4. Export;

5. Gain of Inventory;

6. Loss of Inventory; and

7. Not Used for Transportation; and.

8. Fossil Jet Fuel used for Intrastate Flight.

(B) NGV Fueling;

(C) Propane Fueling;

(D) For the following hydrogen-based transaction types:

~~(C)~~1. Forklift Hydrogen Fueling; and

2. Fuel Cell Vehicle (FCV) Fueling

(E) For the following electricity-based transaction types:

1. EV Charging except as specified under 95491(d)(3)(A);

2. eTRU Fueling;

3. eCHE Fueling;

4. eOGV Fueling;

5. Fixed Guideway Electricity Fueling; and

6. Forklift Electricity Fueling.

~~(D)~~(F) FCV Fueling for hydrogen produced from biomethane supplied using book-and-claim accounting pursuant to section 95488.8(i)(2).

(2) *Verification Schedule.* Entities responsible for verification of Quarterly Fuel Transactions Reports must ensure a transactions data verification statement is submitted to the Executive Officer according to the following schedule.

(A) *Annual Verification.* The entity required to contract for verification of Quarterly Fuel Transactions Reports must ensure a transactions verification statement is submitted annually by August 31, beginning in 2021 for 2020 data, to the Executive Officer for the prior calendar year of data unless specified otherwise in sections 95500(c)(2)(B) or 95500(c)(2)(C).

Quarterly review of a Quarterly Fuel Transactions Report may only be included as part of annual verification services after the entity submits the report and attests that the statements and information submitted are true, accurate, and complete.

~~(B)~~ *Deferred Verification.* ~~Fuel pathway holders producing alternative fuels may defer annual verification of their Quarterly Fuel Transactions Reports for each production facility up to two years if the quantity of fuel produced at the production facility and reported by any entity does not result in 6,000 or more credits and 6,000 or more deficits generated in LRT-CBTS during the prior calendar year.~~

(B) Fuel reporting entities ~~only reporting alternative fuel quantities using Lookup Table Pathways~~ may defer annual verification of their Quarterly Fuel Transactions Reports up to two years if they do not generate 6,000 or more credits and 6,000 or more deficits in LRT-CBTS during the prior calendar year.

Any fuel quantity reported under a pathway with biomethane or hydrogen supplied using book-and-claim accounting pursuant to section 95488.8(i)(2) is not eligible for deferred verification.

The verification body must submit transactions verification statements to the Executive Officer for all prior unverified reports on or before August 31 of the year verification is required or conducted for the ~~production facility~~reporting entity.

(C) *Verification Exemption for Designated Liquid Fuel Transactions.* Entities reporting fuel transactions as Export, Gain of Inventory, Loss of Inventory, and Not Used for Transportation, which do not result in 6,000 or more credits and 6,000 or more deficits generated in LRT-CBTS in a calendar year are exempt from verification of the Quarterly Fuel Transactions Reports for that calendar year if all the following conditions are met:

1. The entity did not report any liquid fuel using the transaction types: Production in California, Production for Import, or Import; and

2. The entity did not report any transactions specified in section 95500(c)(1)(B) ~~or~~through 95500(c)(1)(~~C~~E).

(d) *Verification of Crude Oil Quarterly and Annual Volumes Reports*.

(1) *Applicability.* Entities submitting crude oil volume data must obtain the services of a verification body accredited by the Executive Officer for purposes of conducting verification services, including required site visit(s), for Crude Oil Quarterly and Annual Volumes Reports submitted under this subarticle.

(2) *Verification Schedule.* Entities required to contract for verification of Crude Oil Quarterly and Annual Volumes Reports must ensure a crude oil volume verification statement for the prior calendar year of data is submitted to the Executive Officer annually by August 31~~st~~, beginning in 2021 for 2020 data.

Quarterly review of a Crude Oil Quarterly Volumes Report may only be conducted as part of annual verification services after the entity submits the quarterly report and attests that the statements and information submitted are true, accurate, and complete.

(e) *Verification of Project Reports*.

(1) *Applicability.* The following entities must obtain the services of a verification body accredited by the Executive Officer for purposes of conducting verification services, including required site visit(s), for Project Reports submitted under this subarticle:

(A) Project operators and joint applicants for refinery investment project reports;

(B) Project operators and joint applicants for innovative crude project reports;

(C) Project operators and joint applicants for renewable hydrogen project reports; and

(D) Project operators and joint applicants for direct air capture project reports.

(2) *Verification Schedule.* Entities submitting Project Reports may elect to conduct quarterly or annual verification. Entities must determine before the initial verification of a Project Report whether to conduct quarterly or annual verification. If an entity elects to conduct quarterly verification, it may only switch to annual verification at the beginning of a calendar year.

Entities electing quarterly verification must ensure each quarterly project data verification statement is submitted to the Executive Officer within five months of the Quarterly Project Report deadline beginning with 2020 data.

Entities electing annual verification must ensure annual project data verification statements are submitted to the Executive Officer by August 31, 2021 for submittal of 2020 data, and annually thereafter.

(f) *Verification of Low-Complexity/Low-Energy-Use Refinery Reports*.

(1) *Applicability.* Entities submitting Low-Complexity/Low-Energy-Use refinery data must obtain the services of a verification body accredited by the Executive Officer for purposes of conducting verification services, including required site visit(s), for Low-Complexity/Low-Energy-Use Refinery Reports submitted under this subarticle.

(2) *Verification Schedule.* The verification body must submit an annual verification statement to the Executive Officer for the prior calendar year by August 31, beginning in 2021 for 2020 data.

(g) *Verification Body and Individual Verifier Rotation Requirements.* An entity that is required to contract for validation or verification must not use the same verification body or individual verifier(s) to perform validation and verification services under this subarticle for a period of more than six consecutive years, beginning January 1, 2020.

The six-year period begins on the execution date of the entity's first contract for any validation or verification under this subarticle and ends on the date the final verification statement is submitted. The six-year limit does not reset upon a change in ownership or operational control of the entity required to contract for validation or verification services.

If the entity is required or elects to contract with another verification body or verifier(s), the entity may re-engage the previous verification body or verifier(s) only after three years, except in the case of a set-aside of a validation or verification statement as specified in section 95501. An entity required to contract for validation or verification services must, in time for the next verification, replace a verification body that has a suspended or revoked Executive Order pursuant to MRR section 95132(d), and included by reference in section 95502(a).

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95501. Requirements for Validation and Verification Services.

Validation and verification services must be performed by verification bodies accredited by the Executive Officer; in addition, such services must meet the following requirements (the general term “verification services” includes validation services for fuel pathway applications unless otherwise provided):

(a) *Notice of Verification Services.* The verification body must submit a notice of validation or verification services to the Executive Officer.

For verification bodies, the notice must be submitted to the Executive Officer after the Executive Officer has provided a determination that the potential for a conflict of interest is acceptable, as specified in section 95503(e), and that verification services may proceed. The verification body may begin services for the entity required to contract for verification services after the notice is received by the Executive Officer, but the verification body must allow a minimum of 14 ~~calendar~~ days advance notice of the site visit unless an earlier date is approved by the Executive Officer in writing. In the event that the conflict of interest statement and the notice of verification services are submitted together, services cannot begin until ~~ten calendar~~10 days after the Executive Officer has deemed acceptable the potential for conflict of interest as specified in 95503(e).

The verifier's notice must include all the following information:

(1) A list of personnel who will be designated to provide verification services as a verification team, including the names of each designated employee, the lead verifier, and all subcontractors, and a description of the roles and responsibilities each team member will have. The independent reviewer must also be listed separately.

(2) Documentation that the verification team has the skills required to provide verification services for the entity required to contract for verification services and type of application or report. The notice must include a demonstration that the verification team includes at least one member with specified competency that is not also the independent reviewer, when required below:

(A) Specified competency as evidenced by experience in alternative fuel production technology and process engineering when providing validation services for fuel pathway applications or verification services for Fuel Pathway Reports;

(B) Specified competency as evidenced by accreditation by the Executive Officer as an oil and gas systems specialist pursuant to MRR when providing verification services for Quarterly Fuels Transactions Reports submitted by producers and importers of gasoline or diesel, Crude Oil Quarterly and Annual Volumes Reports, and Project Reports as listed in section 95500.

(3) General information on the entity required to contract for verifications, including:

(A) The entity's name and the facilities and other locations that will be subject to verification services, and the contact, address, telephone number and e-mail address for the entity required to contract for verification services;

(B) The LCFS ID(s) for the entity required to contract for verification services;

(C) The date(s) of the on-site visit, if required in section 95501(b)(3), with physical address and contact information;

(D) A brief description of expected verification services to be performed, including expected completion date, and whether quarterly review is planned in the context of an annual verification requirement.

(4) If any of the information under sections 95501(a)(1) or 95501(a)(2) changes after the notice is submitted to the Executive Officer, the verification body must notify the Executive Officer as soon as the change is made and submit an updated notice of verification services.

The verification body must also submit an updated conflict of interest self-evaluation form with an updated notice of verification services as soon as the change is made. The conflict of interest must be reevaluated pursuant to section 95503(e) and the Executive Officer must approve any changes in writing.

(b) Verification services must include, but are not limited to, the following:

(1) *Validation or Verification Plan.* The verification team must develop a validation or verification plan based on the following:

(A) Information from the fuel pathway applicant, pathway holder, or reporting entity. Such information must include all the following:

1. Information to allow the verification team to develop an understanding of facility or entity boundaries, operations, accounting practices, type of LCFS report(s) the entity is responsible for, LCFS regulatory sections they are subject to, other renewable or low carbon fuels markets they participate in, and other mandatory or voluntary auditing programs they are subject to, as applicable;

2. Organizational chart and list of key personnel involved in developing applications and reports submitted to the Executive Officer, as specified in section 95500, and their qualifications, including training;

3. Description of the specific methodologies used to quantify and report data, as required in this subarticle, which are needed to develop the validation or verification plan, including but not limited to calibration procedures and logs for measurement devices capturing site-specific data;

4. Information about the data management systems and accounting procedures used to capture and track data for fuel pathway application and each type of report as needed to develop the validation or verification plan;

5. Information about the entities in the supply chain upstream and downstream of the fuel producer that contribute to site-specific CI data, including a list of feedstock suppliers and contact names with physical addresses;

6. Evidence demonstrating that any joint applicants are being separately verified and thus are outside the scope of the instant verification services being provided by the verification body; and

7. Previous LCFS validation and verification reports, as applicable, and other audit reports including reports from production or management system certifications and internal audits.

(B) Timing of verification services. Such information must include:

1. Dates of proposed meetings and interviews with personnel of the entity required to contract for verification services;

2. Dates of proposed site visits;

3. Types of proposed document and data reviews and, if applicable, how quarterly review is planned in the context of an annual verification requirement;

4. Expected date for completing validation or verification services.

(2) *Planning Meetings with the Entity Required to contract for Verification Services.* The verification team must discuss with the entity contracting for verification services the scope of the verification services and request any information and documents needed for the verification services.

The verification team must create a draft sampling plan and verification plan prior to the site visit. The verification team must also review the documents provided, and plan and conduct a review of original documents and supporting data for the verification services specified in section 95501.

(3) *Site Visits.* At least one lead LCFS verifier accredited by the Executive Officer on the verification team must, in addition to one visit to validate an application, annually visit each facility; and, if different from the fuel production facility, the central records location for which the records supporting an application or report subject to verification are submitted. Site visits, included voluntarily as part of a quarterly review, may not substitute for the required site visit for annual verification services, which must occur after all LCFS data for the prior calendar year has been submitted to the Executive Officer and attested to.

(A) During site visits, the verification team member(s) must carry out tasks that, in the professional judgment of the team, are necessary, including the following:

1. Review supporting evidence used to develop reports listed in section 95500 submitted to the Executive Officer;

2. Interview key personnel, such as process engineers, metering experts, accounting personnel, and project operators, as well as staff involved in compiling data and preparing the LCFS reports;

3. Review and understand the data management systems and accounting practices used by the entity to acquire, process, track, and report LCFS data. The verification team member(s) must evaluate the uncertainty and effectiveness of these systems;

4. Directly observe production equipment, confirming diagrams for processes, piping, and instrumentation; measurement system equipment; and accounting systems for data types determined in the sampling plan to be high risk;

5. Assess conformance with measurement accuracy requirements specified in this subarticle for measurement devices that do not meet criteria for financial transactions meters, assess the reasonableness of temporary measurement methods, assess conformance with the monitoring plan, and assess conformance with data capture requirements specified in this subarticle, if applicable.

6. Review financial transactions to confirm complete and accurate reporting.

(4) *Sampling Plan.* As part of validating fuel pathway applications and verifying LCFS reports the verification team must develop a sampling plan that meets the following requirements:

(A) The verification team must develop a sampling plan based on a strategic analysis developed from document reviews and interviews to assess the likely nature, scale and complexity of the verification services for the entity required to contract for verification services and type of report. The analysis must include a review of: the inputs for the development of the submitted applications and reports specified in section 95500; the rigor and appropriateness of data management systems; and the coordination within the responsible entity's organization to manage the operation and maintenance of equipment and systems used to complete applications and reports.

(B) The sampling plan must include a ranking of data sources by relative contribution to the data type to be assessed for material misstatement and a ranking of data sources with the largest calculation uncertainty, including risk of incomplete reporting, based on type of report or application.

(C) The sampling plan must include a qualitative narrative of uncertainty risk assessment in the following areas as applicable in this subarticle:

1. Data acquisition equipment;

2. Data sampling and frequency;

3. Data processing and tracking;

4. Tracking of fuel transportation into California to include modes of transportation and distances traveled, as applicable;

5. CI calculations, as applicable;

6. Fuel pathway code (FPC) allocation methodology, as applicable;

7. Management policies or practices in developing LCFS reports.

(D) After completing the analysis required by sections 95501(b)(4)(A) through (C) above, the verification team must include in the sampling plan a list which includes the following:

1. Data sources that will be targeted for document reviews, data checks as specified in 95501(b)(5), and an explanation of why they were chosen;

2. Methods used to conduct data checks for each data type;

3. A summary of the information analyzed in the data checks and document reviews conducted for each data type.

The sampling plan list must be updated and finalized prior to the completion of verification services. The final sampling plan must describe in detail how the identified risks were addressed during the verification. When quarterly reviews are conducted as part of annual verification services, the final sampling plan must describe in detail how the risks and issues identified for the annual data set were addressed during each quarterly review and final annual verification.

(E) *Specified Source Feedstocks.* Specified source feedstocks included in fuel pathway applications and reports that require third-party verification must be included in the scope of verification services. When a fuel pathway does not require third-party validation or verification, e.g., Lookup Table pathways including hydrogen (gaseous and liquefied) from central SMR of biomethane, specified source feedstocks must be included in the scope of verification of the Quarterly Fuel Transactions Reports. The verification team must use professional judgment and include in its risk assessment and sampling plan its analysis of the need for a desk review or site visit for verification of any entity in the feedstock chain of custody. This analysis must include an evaluation of the need to trace feedstock through feedstock suppliers, including aggregators, storage or pretreatment facilities, and traders or brokers, to the point of origin as required in section 95488.8(g). If an error is detected during data checks of records maintained by the entity required to contract for verification services, the verification team must update its risk assessment and sampling plan to assure specified source feedstock characterization and quantities to the point of origin.

(F) The verification team must revise the sampling plan to describe tasks completed by the verification team as information becomes available and potential issues emerge with material misstatement or nonconformance with the requirements of this subarticle.

(G) The verification body must retain the sampling plan in paper or electronic format (which includes digital media) for a period of no less than ten years following the submission of each validation or verification statement. The sampling plan must be made available to the Executive Officer upon request.

(H) The verification body must retain all material received, reviewed, or generated to render a validation or verification statement for the entity required to contract for verification services for a period of no less than ten years. The documentation must allow for a transparent review of how a verification body reached its conclusion in the validation or verification statement, including independent review.

(5) *Data Checks.* To determine the reliability of the submitted data, the verification team must conduct data checks. Such data checks must focus on the most uncertain data and on data with the largest contributions to greenhouse gas emissions (including life cycle greenhouse gas emissions) and greenhouse gas emission reductions. The selection of data checks must meet all the following criteria:

(A) The verification team must use data checks to ensure that the appropriate methodologies have been applied for the data submitted in applications and reports required in this subarticle;

(B) The verification team must choose data checks to ensure the accuracy of the data submitted in applications and reports required in this subarticle;

(C) The verification team must choose data checks based on the relative contribution to greenhouse gas emissions or reductions and the associated risks of contributing to material misstatement or nonconformance, as indicated in the sampling plan;

(D) The verification team must use professional judgment in establishing the extent of data checks for each data type, as indicated in the sampling plan, which are needed for the team to conclude with reasonable assurance whether the data type specified for the application or report is free of material misstatement. At a minimum, the data checks selected by the verification team must include the following:

1. Tracing data in the application or report to its origin;

2. Reviewing the procedure for data compilation and collection;

3. Recalculating intermediate and final data to check original calculations;

4. Reviewing calculation methodologies used by the entity required to contract for verification services for conformance with this subarticle; and

5. Reviewing meter and analytical instrumentation measurement accuracy and calibration for consistency with the requirements of this subarticle.

(E) The verification team is responsible for determining via data checks whether there is reasonable assurance that the application or report conforms to the requirements of this subarticle.

(F) The verification team must compare its own calculated results with the submitted data in order to confirm the extent and impact of any omissions and errors. Any discrepancies must be investigated. The comparison of data checks must also include a narrative to indicate which data were checked, the quantity of data evaluated for each data type, the percentage of reported source data covered by the data checks, and any separate discrepancies that were identified in the application or report.

(6) *Application and Report Modifications.* As a result of data checks by the verification team and prior to completion of a validation or verification statement, the entity required to contract for verification services must fix all correctable errors that affect the data submitted in the application or reports specified in section 95500 and submit a revised application or report to the Executive Officer. Failure to do so before completion of verification services will result in an adverse verification statement. Failure to fix misreported data that do not affect credit or deficit calculations represents a nonconformance with this subarticle but does not, absent other errors, result in an adverse validation or verification statement.

The verification team must use professional judgment in identifying correctable errors as defined in section 95481(a), including determining whether differences are not errors but result from truncation or rounding or averaging.

The verification team must document the source of any difference identified, including whether the difference results in a correctable error or on the other hand, was the result of truncation, rounding, or averaging.

(7) *Findings.* To verify that the application or report is free of material misstatements, the verification team shall make its own calculation of the specified data types reported by substituting the checked data from 95501(b)(5). The verification team must determine whether there is reasonable assurance that the application or report does not contain a material misstatement, as defined for each application or report type in section 95481, and calculated pursuant to section 95501(b)(9) through

(11), using the units required by the applicable parts of this subarticle. To assess conformance with this subarticle, the verification team must review the methods and factors used to develop the application or report for adherence to the requirements of this subarticle and identify whether other requirements of this subarticle are met.

(8) *Log of Issues.* The verification team must keep a log that documents any issues identified in the course of verification services that may affect determinations of material misstatement and nonconformance, whether identified by the verifier, the entity required to contract for verification services, or the Executive Officer, regarding the original or subsequent application or report versions. The issues log must identify the regulatory section related to the nonconformance or potential nonconformance, if applicable, and indicate if the issues were corrected by the entity required to contract for verification services prior to completing the verification services. Any other concerns that the verification team has with the preparation of the application or report must be documented in the issues log and communicated to the entity required to contract for verification services during the course of the verification services. The log of issues must indicate whether each issue has a potential bearing on material misstatement, nonconformance, or both and whether an adverse verification statement may result if not addressed. If quarterly review is conducted before an annual verification, any issues identified must be formalized pursuant to this subsection in the log of issues during the quarterly review. The log of issues for the annual verification must include the cumulative record of issues from all quarterly reviews, as well as the annual verification.

(9) *Material Misstatement Assessments for Fuel Pathways and Quarterly Fuel Transactions.* Assessments of material misstatement are conducted separately on each calculated operational CI value and each quarterly fuel transaction quantity per FPC (expressed in units from the applicable sections of this subarticle). Material misstatement assessments are not conducted for quarterly review.

(A) *Operational CI.* In assessing whether a fuel pathway application or fuel pathway report contains a material misstatement, as defined in section 95481(a), the verification team must populate a controlled version of the ~~Simplified~~Tier 1 CI Calculator for Tier 1 pathways, or CARB-approved CA-GREET~~3~~4.0 for Tier 2 pathways, and determine whether any reported operational CI value contains a material misstatement using the following equations for relative error threshold and absolute error threshold.

The following calculations of relative error threshold, absolute error threshold, and percent error must be included in the final verification report pursuant to section 95501(c)(3)(A)8.

Each fuel pathway CI is subject to data checks in section 95501(b)(5) and must be assessed separately for material misstatement. One or more material misstatements results in a finding of material misstatement for the fuel pathway application or for the fuel pathway report.

$$Percent\ error\ (CI\ ) = \frac{\sum |\ Difference\ in\ CI\ |}{|\ Reported\ Operational\ CI\ |}\ x\ 100\%$$

$$Relative\ error\ threshold\ (CI)$$

$$\underline{= |\ Difference\ in\ CI\ |\ \ \geq 0.05\ x\ |\ Reported\ Operational\ CI\ Value\ |}$$

$$Absolute\ error\ threshold\ (CI)$$

$$\underline{= |\ Difference\ in\ CI\ |\ \ \geq 2.00\ gCO_2e/MJ}$$

where:

"$Difference\ in\ CI$" means the absolute value result of the reported operational CI minus the verifier's calculation of CI. The verifier's calculation of CI is based on site-specific data inputs modified to include discrepancies, omissions, and misreporting found during the course of verification services;

"$Discrepancies$" means any differences between the reported site-specific CI inputs and the verifier's calculated site-specific CI inputs subject to data checks in section 95501(b)(5);

"$Omissions$" means any site-specific CI inputs or associated source data the verifier concludes must be part of the fuel pathway application or fuel pathway report, but were not included;

"$Misreporting$" means duplicate, incomplete or other CI input data the verifier concludes should, or should not, be part of the fuel pathway application or fuel pathway report; and

"$|\ Reported\ Operational\ CI\ Value\ |$" means the absolute value of the operational CI submitted in the fuel pathway application or fuel pathway report.

(B) *Quarterly Fuel Transaction Quantities per FPC.* In assessing whether a quarterly fuel transaction report contains a material misstatement, as defined in section 95481(a), the verification team must determine whether any quarterly fuel transaction quantity per FPC specified in section 95500(c)(1) contains a material misstatement using the following equation. The reported quarterly fuel transaction quantity for an FPC contains a material misstatement if the 5.00 percent error threshold is exceeded. The following calculation of percent error must be included in the final verification report pursuant to section 95501(c)(3)(A)8.

Each aggregated quarterly fuel quantity per FPC is subject to data checks in section 95501(b)(5) and must be assessed separately for material misstatement. One or more material misstatements results in a finding of material misstatement for the verification period.

$$Percent\ error\ (fuel\ transaction\ quantity)$$

$$= \frac{\sum\ [Discrepancies, Omissions, Misreporting]}{Reported\ Quarterly\ Fuel\ Transaction\ Quantity\ for\ FPC}\ x\ 100\%$$

where:

"$Discrepancies$" means any differences between the fuel quantity for the FPC reported in the Quarterly Fuel Transactions Report and the verifier's calculation of fuel quantity subject to data checks in section 95501(b)(5);

"$Omissions$" means any fuel quantity the verifier concludes must be part of the Quarterly Fuel Transactions Report, but was not included;

"$Misreporting$" means duplicate, incomplete or other fuel quantity data the verifier concludes should, or should not, be part of the Quarterly Fuel Transactions Report; and

"$Reported\ Quarterly\ Fuel\ Transaction\ Quantity\ for\ FPC$" means the total of all reported fuel quantities for each FPC for each transaction type specified in section 95500(c)(1) for each quarter for which the verifier is conducting a material misstatement assessment.

(C) When evaluating material misstatement, verifiers must deem correctly substituted missing data to be accurate, regardless of the amount of missing data.

(10) *Material Misstatement Assessment for Project Reports (Project-based Crediting)*.

(A) Verification services, including assessment of material misstatement, are conducted separately for each Project Report. In assessing whether a Project Report contains a material misstatement, as defined in section 95481(a), the verification team must determine whether the greenhouse gas reductions quantified and reported in the Project Report contain a material misstatement using the following equation.

Any discrepancies, omissions, or misreporting found by the verification team must include the positive or negative impact on the total reported greenhouse gas emission reductions when entered in the material misstatement equation. The reported project data contain a material misstatement if the 5.00 percent error threshold is exceeded. The following calculation of percent error must be included in the final verification report pursuant to section 95501(c)(3)(A)8.

$$Percent\ error\ (project\ data\ ) = \frac{\sum\ [Discrepancies, Omissions, Misreporting]}{Reported\ GHG\ Emissions\ Reduction}\ x\ 100\%$$

where:

"$Discrepancies$" means any differences between the reported greenhouse gas emissions reductions in the Project Report and the verifier's calculated value based on data checks required in section 95501(b)(5);

"$Omissions$" means any greenhouse gas emissions, excluding any greenhouse gas reductions, the verifier concludes must be part of the Project Report, but were not included;

"$Misreporting$" means duplicate, incomplete or other greenhouse gas emissions or reductions data the verifier concludes should, or should not, be part of the Project Report;

"$Reported\ GHG\ emissions\ reduction$" means the total of all greenhouse gas emissions reductions reported in the Project Report for which the verifier is conducting a material misstatement assessment.

(B) When evaluating material misstatement, verifiers must deem correctly substituted missing data to be accurate, regardless of the amount of missing data.

(11) *Material Misstatement Assessment for Low-Complexity/Low-Energy-Use Refinery Reports*.

(A) Verifications and assessments of material misstatement are conducted separately for volumes of CARBOB produced from crude oil and for volumes of diesel produced from crude oil for the calendar year. In assessing whether a Low-Complexity/Low-

Energy-Use Refinery Report contains a material misstatement, as defined in section 95481(a), the verification team must determine whether the Low-Complexity/Low-Energy-Use refinery data specified in this subarticle contains a material misstatement using the following equation.

Any discrepancies, omissions, or misreporting found by the verification team must include the positive or negative impact on the total CARBOB or diesel volume produced from crude oil when entered in the material misstatement equation. The reported refinery data contain a material misstatement if the 5.00 percent error threshold is exceeded. The following calculation of percent error must be included in the final verification report pursuant to section 95501(c)(3)(A)8.

$$Percent\ error\ (low\ complexity\ low\ energy\ use\ refinery\ data\ )$$

$$= \frac{\sum\ [Discrepancies, Omissions, Misreporting]}{CARBOB\ or\ Diesel\ Volume\ Produced\ from\ Crude\ Oil}\ x\ 100\%$$

where:

"$Discrepancies$" means any differences between the sum of the quarterly volumes of CARBOB or diesel produced from crude oil reported in the Low-Complexity/Low-Energy-Use Refinery Report and the verifier's calculation based on data checks in section 95501(b)(5);

"$Omissions$" means any volume of CARBOB or diesel produced from crude oil or associated source data the verifier concludes must be part of the Low-Complexity/Low-Energy-Use Refinery Report, but was not included;

"$Misreporting$" means duplicate, incomplete or other refinery data the verifier concludes should, or should not, be part of the Low-Complexity/Low-Energy-Use Refinery Report;

"$CARBOB\ or\ Diesel\ Volume\ Produced\ from\ Crude\ Oil$" means the sum of the quarterly volumes of CARBOB or diesel produced from crude oil in a calendar year reported in the Low-Complexity/Low-Energy-Use Refinery Report for which the verifier is conducting a material misstatement assessment.

"$CARBOB\ Volume\ Produced\ from\ Crude\ Oil$" and "$Diesel\ Volume\ Produced\ from\ Crude\ Oil$" are separately subject to data checks in section 95501(b)(5) and must be assessed separately for material misstatement. One or more material misstatements results in a finding of material misstatement for the Low-Complexity/Low-Energy-Use Refinery Report.

(B) When evaluating material misstatement, verifiers must deem correctly substituted missing data to be accurate, regardless of the amount of missing data.

(12) *Crude Oil Quarterly and Annual Volumes Reports.* Material misstatement assessment does not apply to data submitted in crude oil quarterly and annual volumes reports, but the data must be assessed for reasonable assurance of conformance with this subarticle.

(13) *Review of Missing Data Substitution.* If a source selected for a data check was affected by a loss of data used for the reported data in the application or report, pursuant to this subarticle:

(A) The verification team must confirm that the reported data were calculated using:

1. the applicable missing data procedures, or

2. an Executive Officer approved alternate method

~~2.~~ a ~~reasonable~~ temporary method~~, or~~

3. as permitted under section 95491.2(b)(2)(A) and described in section 95481. A temporary method may be used for a source that was affected by a loss of data for a period not to exceed six months. Missing data covering a period of time longer than six months during a calendar year requires an Executive Officer approved alternate method.

(B) The verifier must note the date, time and source of any missing data substitutions discovered during the course of verification in the validation or verification report.

(c) Completion of verification services must include:

(1) *Validation or Verification Statement.* Upon completion of the verification services specified in section 95500, the verification body must complete a validation or verification statement, and provide its statement to the entity required to contract for verification services and Executive Officer by the applicable verification deadline specified in section 95500. Before the validation or verification statement is completed, the verification services and findings of the verification team must be independently reviewed by an employee of the verification body who is an accredited lead verifier not

involved in verification services for the entity required to contract for verification services during that application period or reporting period.

(2) *Independent Review*. The independent reviewer must serve as a final check on the verification team's work to identify any significant concerns, including:

(A) Errors in planning,

(B) Errors in data sampling, and

(C) Errors in judgment by the verification team that are related to the draft validation or verification statement.

The independent reviewer must maintain independence from the verification services by not making specific recommendations about how the verification services should be conducted. The independent reviewer will review documents applicable to the services provided, and identify any failure to comply with requirements of this subarticle or with the verification body's internal policies and procedures for providing verification services. The independent reviewer must concur with the verification findings before the validation or verification statement is issued.

(3) *Completion of Findings and Validation or Verification Report and Statement.* The verification body is required to provide each entity required to contract for verification services with the following:

(A) A detailed validation or verification report, which must at a minimum include:

1. A detailed description of the facility or entity including all data sources and boundaries;

2. A detailed description of the data management system and accounting procedures;

3. A detailed description of entities in the supply chain contributing CI parameters;

4. The validation or verification plan;

5. The detailed comparison of the data checks conducted during verification services;

6. The log of issues identified in the course of verification services and their resolution;

7. Any qualifying comments on findings during verification services;

8. Findings of omissions, discrepancies, and misreporting and the material misstatement calculations required in section 95501(b)(9) through (11).

(B) The validation or verification report must be submitted to the entity required to contract for verification services at the same time as or before the final validation or verification statement is submitted to the Executive Officer. The detailed validation or verification report must be made available to the Executive Officer upon request.

(C) The verification team must have a final discussion with the entity required to contract for verification services explaining its findings, and notify the entity required to contract for verification services of any unresolved issues noted in the issues log before the validation or verification statement is finalized.

(D) The verification body must provide the validation or verification statement to the entity required to contract for verification services and the Executive Officer, attesting whether the verification body has found the submitted application or report to be free of material misstatement, and whether the application or report is in conformance with the requirements of this subarticle. For every qualified positive validation or verification statement, the verification body must explain the nonconformances contained within the application or report, and must cite the section(s) in this subarticle that corresponds to the nonconformance and why the nonconformances do not result in a material misstatement. For every adverse validation or verification statement, the verification body must explain all nonconformances or material misstatements leading to the adverse validation or verification statement and must cite the sections in this subarticle that correspond to the nonconformance and material misstatements.

(E) The lead verifier on the verification team must attest that the verification team has carried out all verification services as required by this subarticle. The lead verifier who has conducted the independent review of verification services and findings must attest to his or her independent review on behalf of the verification body and his or her concurrence with the findings.

1. The lead verifier must attest in the validation or verification statement, in writing, to the Executive Officer as follows:

"I certify under penalty of perjury under the laws of the State of California that the verification team has carried out all validation or verification services as required by this subarticle."

2. The lead verifier who has conducted the independent review of verification services and findings must attest in the validation or verification statement, in writing, to the Executive Officer as follows:

"I certify under penalty of perjury under the laws of the State of California that I have conducted an independent review of the validation or verification services and findings on behalf of the verification body as required by this subarticle and that the findings are true, accurate, and complete."

(4) *Adverse validation or verification statement and petition process.* Prior to the verification body providing an adverse validation or verification statement for the application or report to the Executive Officer, the verification body must notify the entity required to contract for verification services and the entity required to contract for verification services must be provided at least 14 ~~calendar~~ days to modify the application or report(s) to correct any material misstatement or nonconformances found by the verification team. The verification body must provide notice to the Executive Officer of the potential for an adverse validation or verification statement at the same time it notifies the entity required to contract for verification services, and include a current issues log. The modified application or report and validation or verification statement must be submitted to the Executive Officer before the verification deadline, even if the entity required to contract for verification services makes a request to the Executive Officer as provided below in section 95501(c)(4)(A).

(A) If the entity required to contract for verification services and the verification body cannot reach agreement on modifications to the data that result in a positive validation or verification statement, the responsible entity may, before the validation or verification deadline and before the validation or verification statement is submitted, petition the Executive Officer to make a final decision as to the verifiability of the submitted application or report. At the same time that the entity required to contract for verification services petitions the Executive Officer, the entity required to contract for verification services must submit all information it believes is necessary for the Executive Officer to make a final decision.

(B) The Executive Officer shall make a final decision no later than October 31~~st~~ following the submission of a petition pursuant to section 95501(c)(4)(A). If at any point the Executive Officer requests information from the verification body, or the entity required to contract for verification services, the information must be submitted to the Executive Officer within ~~ten calendar~~10 days. The Executive Officer will notify the entity required to contract for verification services and the verification body of its determination.

(d) *Validated Applications and Verified Reports Considered Final by the Executive Officer.* Upon provision of a validation or verification statement to the Executive Officer, the reported data is deemed final by the Executive Officer. No changes may be made to the application or report as submitted to the Executive Officer, and all verification requirements of this subarticle shall be considered complete except in the circumstance specified in section 95501(e).

(e) *Set Aside of Validation or Verification Statement.* If the Executive Officer finds a high level of conflict of interest existed between a verification body and a reporting entity, an error is identified, or an application or report that received a positive or qualified positive verification statement fails an audit by the Executive Officer, the Executive Officer may set aside the positive or qualified positive verification statement issued by the verification body, and require the reporting entity to have the report re-verified by a different verification body within 90 ~~calendar~~ days. In instances where an error to a report is identified and determined by the Executive Officer to not affect the final value submitted in the application or report, the change may be made without a set aside of the positive or qualified positive verification statement.

(f) *Executive Officer Audits and Data Requests to the Entity Required to Contract for Verification Services.* Upon request by the Executive Officer, the entity required to contract for verification services must provide the data used to generate the application or report including all data available to a verifier in the conduct of validation or verification services, within 14 ~~calendar~~ days. Upon written notification by the Executive Officer, the entity required to contract for verification services must make available for an Executive Officer audit itself, its personnel, and other entities in its feedstock and finished fuel supply chain, as applicable.

(g) *Executive Officer Audits and Data Requests to the Verification Body.* Upon request by the Executive Officer, the verification body must provide the Executive Officer the validation or verification report given to the entity required to contract for verification services, as well as the sampling plan, contracts for verification services, and any other supporting documents and calculations, within 14 ~~calendar~~ days. Upon written notification by the Executive Officer, the verification body must make itself and its personnel available for an Executive Officer audit.

(h) *Eligibility for Less Intensive Verifications*. Upon receiving a positive verification statement under full verification requirements, fuel reporting entities required to obtain the services of a verification body under section 95500 and only reporting electricity transactions identified in section 95500(c)(1)(E) may choose to obtain less intensive verification services for the following two annual verifications of their Quarterly Fuel Transactions Reports. Otherwise eligible entities must obtain full verification services if any of the following conditions apply:

(1) There has been a change in the verification body;

(2) An adverse verification statement or qualified positive verification statement was issued for the previous annual report;

(3) A change of operational control of the entity required to obtain the services of a verification body under section 95500 occurred in the previous year;

(4) The verification body must provide information on the causes of a change and justification in the verification report if a full verification was not conducted in instances where the following differences from the previous annual report occur:

(A) The annual sum of the four Quarterly Fuel Transaction Quantities differs by more than 25%.

(5) Nothing in this paragraph shall be construed as preventing a verification body from performing a full verification if it is deemed necessary to reach reasonable assurance.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95502. Accreditation Requirements for Verification Bodies, Lead Verifiers, and Verifiers.

(a) Verification bodies, lead verifiers, and non-lead verifiers that will provide verification services (including validation services) under this subarticle must become accredited through fulfilling the accreditation requirements set forth in MRR sections 95132(b) through (e), with the exception of subsections 95132(b)(1)(G), 95132(b)(2), 95132(b)(3), 95132(b)(5), and 95132(e)(1).

MRR text is as referred to, except as otherwise specifically provided:

(1) Wherever “section 95102(a)” is referenced, “section 95481” must be substituted. Wherever “section 95132(b)(2) is referenced, “section 95502(c)” must be substituted. Wherever “section 95133” is referenced, “section 95503” must be substituted.

(2) Whenever “Performance Review” is referenced, the definition in 95481(a) of this subarticle must be substituted.

(b) The Executive Officer may issue accreditation to verification bodies, lead verifiers, and non-lead verifiers that meet the requirements specified in this section.

(1) *Verification Body Accreditation Application.* In addition to the requirements specified in MRR section 95132(b)(1), the applicant must submit the following to the Executive Officer:

(A) Documentation that the proposed verification body has procedures and policies to support staff technical training as it relates to validation or verification. This training must include CARB's verifier training curriculum and be provided by a verification body or verification body applicant to its employees and subcontractors that participate on verification teams. Participation of individual verifiers, including verifiers that are not acting as lead verifiers, must be documented.

(B) The verification body's templates for risk assessment, sampling, and log of issues for the entity types and report types the verification body intends to verify, as specified in section 95500.

(C) Verification body staffing changes are considered an amendment to the verification body accreditation application and therefore the Executive Officer must be notified of any such changes.

(2) *Verifier Accreditation Application.* To apply for accreditation as a lead verifier, the applicant must submit documentation to the Executive Officer that provides the evidence that the applicant meets the criteria in sections 95502(c)(1) though (6). To apply for accreditation as a non-lead verifier, the applicant must submit documentation to the Executive Officer that provides the evidence that the applicant meets the criteria in sections 95502(c)(1) through (2).

(c) *Verifier Competency Requirements.* To perform LCFS verifications, verifiers must be employed by, or contracted with, a verification body accredited by the Executive Officer and submit evidence to demonstrate that competency requirements are met.

(1) Verifiers must provide evidence demonstrating the minimum educational background required to act as a verifier for CARB. Minimum educational background means that the applicant has either:

(A) A bachelor's level college degree or equivalent in engineering, science, technology, business, statistics, mathematics, environmental policy, economics, or financial auditing; or

(B) Evidence demonstrating the completion of significant and relevant work experience or other personal development activities that have provided the applicant with the communication, technical, and analytical skills necessary to conduct verification.

(2) Verifiers must provide evidence demonstrating sufficient workplace experience to act as a verifier, including evidence that the applicant verifier has a minimum of two years of full-time work experience in a professional role involved in emissions data management, emissions technology, emissions inventories, environmental auditing, financial auditing, life cycle analysis, transportation fuel production, or other technical skills necessary to conduct verification.

(3) To act as a lead verifier, in addition to the qualifications in sections 95502(c)(1) and (2), one of the following qualifications must be met:

(A) The verifier must have participated within the previous two years as part of the verification team in at least three completed LCFS validations or verifications under the supervision of a lead verifier accredited under this subarticle by the Executive Officer;

(B) The verifier must be accredited as a lead verifier under MRR or the Cap-and-Trade Regulation by the Executive Officer;

(C) The verifier must have experience acting as the lead on an attestation engagement services team for the U.S. EPA Renewable Fuel Standard (RFS) program within the previous two years or currently be acting as a team lead;

(D) The verifier must have experience acting as the lead on a Quality Assurance Program (QAP) services team for the U.S. EPA RFS program within the previous two years or currently be acting as a team lead;

(E) The verifier must have experience acting as a ~~the~~ lead on a biofuels certification audit within the previous two years or currently be acting as a lead under one of the following international certification systems: International Sustainability and Carbon Certification (ISCC), Roundtable on Sustainable Biomaterials (RSB), or Bonsucro; or

(F) The verifier must have worked as a project manager or lead person for no less than four years, of which two may be graduate level work:

1. In the development of greenhouse gas or other air emissions inventories; or,

2. As a lead environmental data or financial auditor.

(G) Candidates meeting one of the lead verifier qualifications in sections 95502(c)(3)(A) through (E) must complete training specific to the LCFS program to become a lead verifier under this subarticle.

Candidates applying under section 95502(c)(3)(F) for accreditation as a lead verifier under this subarticle must take the CARB-approved comprehensive general verification training and examination in addition to the training specific to the LCFS program.

(4) To become accredited as a lead verifier for validation of fuel pathway applications (CI) or verification of Fuel Pathway Reports (CI) as specified in section 95500(a) and 95500(b), in addition to the qualifications in sections 95502(c)(1) through (3), the verifier must have experience in alternative fuel production technology and process engineering.

(5) To become and remain accredited as a lead verifier for verification of Quarterly Fuel Transactions Reports submitted by producers and importers of gasoline or diesel, Low-Complexity/Low-Energy-Use Refinery Report, Crude Oil Quarterly and Annual Volume Reports, and Project Reports as specified in section 95500, in addition to the qualifications in sections 95502(c)(1) through (3), the verifier must be accredited as an oil and gas systems specialist pursuant to MRR section 95131(a)(2).

(6) Nothing in this section shall be construed as preventing the Executive Officer from requesting additional information or documentation from a verifier or affiliated verification body to demonstrate that the verifier meets the competency requirements set forth here, or from seeking additional information from other persons or entities regarding the verifier's fitness for qualification.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95503. Conflict of Interest Requirements for Verification Bodies and Verifiers.

(a) *Applicability of Conflict of Interest Provisions.* The conflict of interest provisions of this section shall apply to verification bodies and lead verifiers, including independent reviewers, accredited by the Executive Officer to perform LCFS validation and verification services for responsible entities and must apply to all verification team members.

Any individual person or company that is hired by the entity required to contract with a verification body on behalf of the entity required to contract for verification services is also subject to the conflict of interest assessment in this subarticle. In such instances, the verification body must assess the potential conflict of interest between itself and the contracting entity as well as between itself and the responsible entity, and must also address the potential conflict of interest between the contracting entity and the responsible entity, including a written assessment provided and signed by the contracting entity.

(1) "Member" for the purposes of this section means any employee or subcontractor of the verification body or its related entities.

(2) "Related Entity" for the purposes of this section means any direct parent company, direct subsidiary, or sister company.

(3) "Lookback Period" for the purposes of this section means to disclose services provided and assess potential for conflicts of interest beginning five years preceding the start of verification services.

(4) Emerging conflicts of interest must also be monitored. The monitoring period for determining emerging conflicts of interest is during the period verification services are offered and one year after verification services are completed.

(b) *Disclosure of Services with High Potential for Conflict of Interest.* If any of the following occurred during the lookback period, the activity or activities must be disclosed to the Executive Officer with a description of actions the verification body has taken to avoid, neutralize, or mitigate any ongoing potential for conflict of interest.

The potential for a conflict of interest must be deemed high if any of the following occurred during the lookback period. If the Executive Officer determines the verification body or its related entities or any member of the verification team meets the criteria specified in section 95503(b), the Executive Officer shall find a high potential conflict of interest~~ with the following exceptions:~~.

~~Prior to August 31, 2023, the Executive Officer shall deem the following services to be medium potential for conflict of interest and allow verification services to proceed when the verification body or its related entities or a member of the verification team has provided the services listed in sections 95503(b)(2)(A), (B), (C), (E), (G), (H), (I), or (N) within the five year lookback period, provided that the potential conflict of interest is mitigated by meeting the minimum mitigation plan requirements in section 95503(d)(1). On and after August 31, 2023, if any of the situations or services listed in section 95503(b) occurred during the five year lookback period by a verification body and its related entities or a verification team member, verification services may not proceed and rotation is required.~~

(1) Organizational High Potential Conflict of Interest Conditions. The verification body and responsible entity share any management staff or board of directors membership, or any of the senior management staff of the responsible entity have been employed by the verification body, or vice versa; or

(2) Organizational and Individual High Potential Conflict of Interest Conditions. Any employee of the verification body, or any employee of a related entity, or a subcontractor who is a member of the verification team has provided to the responsible entity any of the following services:

(A) Designing, developing, implementing, reviewing, or maintaining an information or data management system for data submitted pursuant to this subarticle or MRR unless the review was part of providing independent quality assurance audit services, attestation engagement services, providing validation or verification services pursuant to the U.S. EPA RFS or the EU RED, or third-party engineering reports pursuant to the U.S. EPA RFS;

(B) Developing CI or fuel transaction data or other greenhouse gas-related engineering analysis that includes facility-specific information;

(C) Designing or providing consultative engineering or technical services in the development and construction of a fuel production facility; or energy efficiency, renewable power, or other projects which explicitly identify greenhouse gas reductions as a benefit;

(D) Designing, developing, implementing, conducting an internal audit, consulting, or maintaining a greenhouse gas emissions reduction or greenhouse gas removal offset project as defined in the Cap-and-Trade Regulation and reported to the Executive Officer, or a project to receive LCFS project-based credits;

(E) Preparing or producing LCFS fuel pathway application or LCFS reporting manuals, handbooks, or procedures specifically for the responsible entity;

(F) Directly managing any health, environment or safety functions for the responsible entity;

(G) Any service related to development of information systems, or consulting on the development of environmental management systems is considered high conflict of interest except for systems that will not be part of the validation or verification process and except for accounting software systems;

(H) Verification services that are not conducted in accordance with, or equivalent to, section 95503 requirements, unless the systems and data reviewed during those services, as well as the result of those services, will not be part of the verification process;

(I) Reporting pursuant to this subarticle, or uploading data for the Executive Officer, on behalf of the entity required to contract for verification services;

(J) Owning, buying, selling, trading, or retiring LCFS credits, RINs, or credits in any carbon market;

(K) Dealing in or being a promoter of credits on behalf of the responsible entity;

(L) Appraisal services of carbon or greenhouse gas liabilities or assets;

(M) Brokering in, advising on, or assisting in any way in carbon or greenhouse gas-related markets;

(N) Bookkeeping and other non-attest services related to accounting records or financial statements, excluding services and results of those services that will not be part of the validation or verification process;

(O) Appraisal and valuation services, both tangible and intangible;

(P) Any actuarially oriented advisory service involving the determination of amounts recorded in financial statements and related accounts;

(Q) Any internal audit service that has been outsourced by the entity required to contract for verification services that relates to the entity's internal accounting controls, financial systems or financial statements, unless the result of those services will not be part of the verification or validation process;

(R) Fairness opinions and contribution-in-kind reports in which the verification or validation body has provided its opinion on the adequacy of consideration in a transaction, unless the resulting services will not be part of the verification or validation process;

(S) Acting as a broker-dealer (registered or unregistered), promoter or underwriter on behalf of the responsible entity;

(T) Any legal services;

(U) Expert services to the entity required to contract for verification services, a trade or membership group to which the entity required to contract for verification services belongs, or a legal representative for the purpose of advocating the entity's interests in litigation or in a regulatory or administrative proceeding or investigation.

(3) *Prohibition on Monetary or Non-Monetary Incentives.* The potential for conflict of interest shall be disclosed and deemed to be high when any member of the verification body provides any type of monetary or non-monetary incentive to an entity required to contract for verification services to secure a validation or verification services contract.

The potential for conflict of interest shall be deemed to be high when any member of the entity required to contract for verification services provides any type of monetary or non-monetary incentive to a member of the verification body to influence validation or verification documentation or findings.

(4) Potential for High Conflict of Interest if Rotation Limit Exceeded. The potential for a conflict of interest shall also be disclosed and deemed to be high where any member of the verification body or verification team has provided verification services for the entity required to contract for verification services except within the time periods in which the entity required to contract for verification services is allowed to use the same verification body or team members as specified in section 95500(g).

(c) *Low Conflict of Interest.* The potential for a conflict of interest shall be deemed to be low where the following conditions are met:

(1) No potential for a high conflict of interest is found pursuant to section 95503(b); and

(2) Any services provided by any member of the verification body or verification team to the entity required to contract for verification, within the look-back period specified in section 95503(a)(3), are valued at less than 20 percent of the fee for the proposed verification services. Any verification conducted in accordance with, or substantially equivalent to, section 95503 provided by the verification body or verification team outside the jurisdiction of the Executive Officer is excluded from this financial assessment, but must be disclosed to the Executive Officer in accordance with section 95503(e).

(3) Non-CARB verification services are excluded from categories of risk if those services are conducted in accordance with, or substantially equivalent to, section 95503, including, but not limited to, auditing services provided under the U.S. EPA RFS (QAP services, attest engagement

services, third-party engineering reports), third-party certification of environmental management systems under ISO 14001, energy management systems under 50001 standards, or certification systems recognized by other governmental agencies, including the European Commission. Verification services provided under MRR or the Cap-and-Trade Regulation are also excluded from categories of risk for potential conflict of interest.

(d) *Medium Conflict of Interest.* The potential for a conflict of interest shall be deemed to be medium where the potential for a conflict of interest is not deemed to be either high or low as specified in sections 95503(b) and 95503(c). The potential for conflict of interest will also be deemed to be medium where there are any instances of personal or familial relationships between the members of the verification body and management or members of the entity required to contract for verification services.

(1) If a verification body identifies a medium potential for conflict of interest and intends to provide verification services for the entity required to contract for verification services, the verification body shall submit, in addition to the submittal requirements specified in section 95503(e), a plan to avoid, neutralize, or mitigate the potential conflict of interest situation. At a minimum, the conflict of interest mitigation plan shall include:

(A) A demonstration that any individuals with potential conflicts have been removed and insulated from the project.

(B) An explanation of any changes to the organizational structure or verification body to remove the potential conflict of interest. A demonstration that any unit with potential conflicts has been divested or moved into an independent entity or any subcontractor with potential conflicts has been removed.

(C) Any other circumstance that specifically addresses other sources for potential conflict of interest.

(2) The Executive Officer shall evaluate the conflict of interest mitigation plan and determine whether verification services may proceed pursuant to section 95503(e).

(e) *Conflict of Interest Submittal Requirements for Accredited Verification Bodies.* Verification bodies accredited by the Executive Officer to perform validation or verification services must adhere to the conflict of interest submittal, determinations, and monitoring requirements in MRR section 95133(e) through (g), except section 95133(f)(2) and (3). Except as otherwise specifically provided:

(1) Wherever the term “reporting entity” is used, the term “entity required to contract for validation or verification services” shall be substituted;

(2) Whenever the term “emissions data report” is used, the term “applications or reports specified in section 95500 of this subarticle” shall be substituted;

(3) Whenever the term “verification services” is used, the term “verification or validation services” shall be substituted;

(4) Wherever “section 95133(a)-(d)” referenced, “section 95503(a)-(d)” shall be substituted; and

(5) When potential for a conflict of interest is deemed to be low, as specified in section 95503(c), the verification body must submit its self-assessment to the Executive Officer, except the Executive Officer authorization to perform verification services as specified in MRR sections 95133(e)(1) and 95133(f)(3) is not required prior to performing LCFS verification services.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

RE: Sevana Bioenergy Comments Regarding ISOR for the Low Carbon Fuel Standard

Dear Mr. Botill:

Thank you for the opportunity to submit comments in response to the Proposed Amendments (Proposed Rule) and associated Initial Statement of Reasons (ISOR) for the Low Carbon Fuel Standard (LCFS) released December 19, 2023. By way of background, Sevana Bioenergy develops RNG projects through design, construction, and operations, with strong partnerships and contributions to the local communities we serve. Our mission is to accelerate the production of RNG from anaerobic digestion facilities and contribute significantly to worldwide greenhouse gas reduction with net carbon-negative projects.

Sevana has staff based in California who have participated in the LCFS for nearly 15 years. We support the need for this rulemaking process to increase and extend LCFS targets that keep key successful elements intact, while enhancing the areas noted below. As you consider comments on this round of rulemaking, Sevana Bioenergy would like to offer the following feedback for your consideration.

Reduce the excess credit bank

Sevana Bioenergy applauds CARB's commitment to reducing carbon intensity and is pleased to see an initial proposed reduction target of at least 30% minimum and 18.75% step down for 2025. However, these targets remain lower than recommended in our letter from March 2023. In the meantime the credit bank has grown even faster than previously expected. The bank of over 20 million credits has depressed prices below the cost of production and return on capital needed to make ambitious investments in low carbon fuel sources and adopt lower emission vehicle technologies, stalling progress until these excess credits are absorbed and supply-demand balance reestablished.

We suggest the following three step solution to include in the final rulemaking:

Set the 2025 step down to 25%

216.1 We recommend a step down to 25% in 2025, or even by mid-2024. This magnitude of step down is essential to enable the LCFS to "catch up" and absorb the large supply of banked credits. This change could be implemented XXX.1 with minimal recycling of CARB's previous modelling as it would simply bring the targets in line with renewable diesel, electricity, and RNG utilization in California. This larger step down is also needed to mitigate the supply-demand balance impact from the new ULSD baseline (105.76). Without changing the 2030 target beyond the associated modelling, this near term step down demand signal is needed to sustain momentum to reach more ambitious targets proposed after 2030.

Strengthen the AAM's mechanics

216.2 We recommend three changes to the auto acceleration mechanism (AAM): First, allow it to take effect in 2027 (or 2026 if the 2025 step down remains less than 25%). Secondly, implement the triggering threshold when the
XXX.2 credit bank is more than 2.0 times greater than the quarterly deficits generated, based on analysis by AJW and others that 3.0 is excessive. Finally, the AAM should allow for the program to trigger continuously (no "freeze" needed between years as currently proposed). These adjustments to the AAM will ensure it is effective enough to avoid repeat regulatory revisions and give sufficient confidence to market participants to make informed investments and long term commitments.

Consider increasing the 2030 target

Based on our review and independent runs of the CATS model, we note generally high cost and limited availability assumptions may skew the results to predict too high prices with too few substitutes. In the future, implementing learning curves and Monte Carlo scenarios across ranges of assumptions could provide additional insights for
216.3 policy making. We respectfully propose CARB consider implementing at least a 35% target in 2030, especially if
XXX.3 the AAM and step down above is not fully implemented. This would also better align the pre-2030 and post-2030 annual targets (vs back-end loading post-2030).

True-up Temporary Pathway Codes

A true-up remains necessary to properly recognize the true environmental performance of all pathways for Temporary Pathway Code (TPC) time periods. Under industry-standard carbon intensity sliding scale contracts the TPC's worse-than-actual carbon intensity disproportionately shifts economics away from producers during the critical "valley of death" shortly after startup but before provisional pathway revenues are realized.

Extending the proposed ISOR true-up to also apply to TPCs is a simple fix to ensure correct accounting for actual GHG benefits delivered so that producers have adequate economics to bring new fuel sources online.

Furthermore, the penalty for inadvertently overstated carbon intensities during the true-up should be revised to 1.25x rather than 4.0x to penalize but not bankrupt producers that do not achieve carbon intensity modelled with best available information but fall short due to factors outside their control.

Streamline Tier 1 Pathway calculators

We support improvements to the Tier 1 calculators to improve processing timelines and streamline verification currently requiring Tier 2 pathways. We would recommend the Tier 1 DSW model enable entering 0, 1, or more lagoon cleanouts per year based on verified inputs. We also support recognizing the latest science finding higher methane emissions are otherwise generated from organic waste prior to processing in anaerobic digestors.

Maintain avoided methane and deliverability mechanics

Sevana is developing projects both inside and outside California, with both carbon negative electricity and RNG pathways, so we are familiar with and not biased toward any specific fuel type or geography. Furthermore, RNG can be used to generate hydrogen and other low carbon fuels. The science-based, technology-neutral and inter-state commerce compliant framework of the LCFS make it a strong and tested policy.

We recommend CARB maintain or extend the timeframes in the ISOR for eligibility of avoided methane deliverability. These mechanisms are supported by science and aligned with programs such as the RFS and other state LCFS. This will avoid tremendous risk of legal challenges, fuel shortages, higher emissions through workarounds such as trucking rather than pipeline deliveries, and perpetuating the sustained usage of fossil fuels by arbitrarily hindering low carbon fuels.

Methane is one of the most powerful greenhouse gases with a potency nearly 30 times that of carbon dioxide. RNG projects capture methane including from livestock and organic waste that would otherwise be released to the atmosphere and thus reduce greenhouse gas emissions and improve air quality. California should employ all options available to help mitigate methane emissions.

We hope these comments and suggestions are helpful to consider in the final rulemaking.

Sincerely,

Steve Compton

Re: Comments on the California Air Resources Board's Proposed Amendment Order to the Low Carbon Fuel Standard (LCFS)

Dear Chairwoman Randolph and Honorable Board Members:

Marathon Petroleum Company LP (MPC) appreciates the opportunity to provide comments to the California Air Resources Board's Proposed Amendment Order to the LCFS.

MPC is a wholly owned subsidiary of Marathon Petroleum Corporation, a leading, integrated, downstream energy company headquartered in Findlay, Ohio. MPC is a supplier of fuels in the State of California and MPC, both directly and through its subsidiaries, is investing in low-carbon solutions to meet the energy demands of today and into the future. MPC's commitment to low-carbon solutions is reflected in the successful conversions of its Dickinson, North Dakota and Martinez, California petroleum refineries into renewable fuel production facilities. Combined, these two operating facilities are expected to produce up to 2.5 million gallons per day of renewable transportation fuel from renewable feedstock sources with an aggregate life-cycle carbon intensity that is approximately 60 percent less than petroleum-based fuels.

The proposed amendments include several changes that MPC has provided comments to in previous workshops. MPC is supportive of several of the proposed amendments, and comments included here will focus on recommendations MPC believes are vital to enhancing the LCFS's ability to provide a strong stable signal and incentivize new low carbon technology use in the transportation fuel sector.

MPC's recommendations on the proposed amendment order are listed below. Additional discussion and support for these recommendations are provided in the subsequent sections.

- MPC recommends CARB recognize the carbon-reducing practices implemented by farmers in its Feedstock Sustainability requirement if it intends to implement a costly and complex Feedstock Sustainability program.
- MPC recommends CARB support the use of renewable natural gas as a feedstock for hydrogen production at a facility.

- MPC recommends CARB reconsider its proposal to add Attestation Letter requirements to the Specified Source Feedstock supply chain.
- MPC recommends CARB make the position holders of jet fuel in the tanks at an airport the First Fuel Reporting Entities.
- MPC recommends CARB not sunset the Refinery Investment Credit provision in 2040 and allow for additional process improvement projects after 2025.
- MPC recommends CARB address the issues MPC identified in CA GREET 4.0 and associated Tier 1 calculators.

The Feedstock Sustainability requirements stop short of recognizing emission reductions farmers are making today while adding costs and additional complexity to a complex feedstock supply chain.

217.1 MPC does not support a cap on crop-based feedstocks[1] and appreciates that the proposed amendments do not establish a cap. MPC has stated previously that a cap on feedstocks will slow progress of meaningful new farming practices. These practices, shown to enhance soil fertility, reduce fertilizer use, and increase soil organic carbon levels[2], can result in lower emissions within the transportation sector.

As an alternative to capping and restricting the use of crop-based feedstocks in the LCFS, CARB has proposed approving third-party programs to certify the sustainability of crop-based feedstocks used to produce transportation fuel that generates LCFS credits. This feedstock sustainability concept[3] includes smart agricultural practices that farmers are utilizing today but does not include a system for recognizing the carbon intensity reduction from such agricultural practices in the renewable fuels CI score. As discussed in the next paragraphs, a third-party certification program will add burden and costs, especially for farmers. Certifying 217.2 certain crop-based feedstocks as having a lower CI score can incentivize smart agricultural practices and help offset costs of the program.

As a producer of renewable diesel that relies on the crop-based feedstock supply chain within the U.S. and abroad, MPC is concerned about the proposal to add a certification process to the very complex U.S. crop-217.3 based feedstock supply chain as the process will increase costs to produce renewable diesel and potentially trigger feedstock supply disruptions, limiting renewable fuel production. The crop-based feedstock supply chain connects small family farms and corporate farms to grain elevators, transporters, and crushers to fuel producers and suppliers of renewable fuels. Most grain used to produce crop-based feedstocks are comingled several times throughout the supply chain. For example, after soybeans are harvested and dried, they are transported and comingled with other harvested soybeans, at grain terminals, elevators, and processing facilities for crushing[4]. Transportation methods will vary throughout the feedstock supply chain and includes rail, ship/barge, and trucks. Because the soybeans from multiple farms are commingled, any process developed to track the amount of sustainably certified soybeans used by a fuel pathway holder must 217.4 incorporate a material balance approach. Only a material balance approach will make it possible to track the amount and sustainability characteristics of such crops throughout the supply chain. Additionally, a material balance approach will prevent creating a system that requires segregation, leading to unnecessary

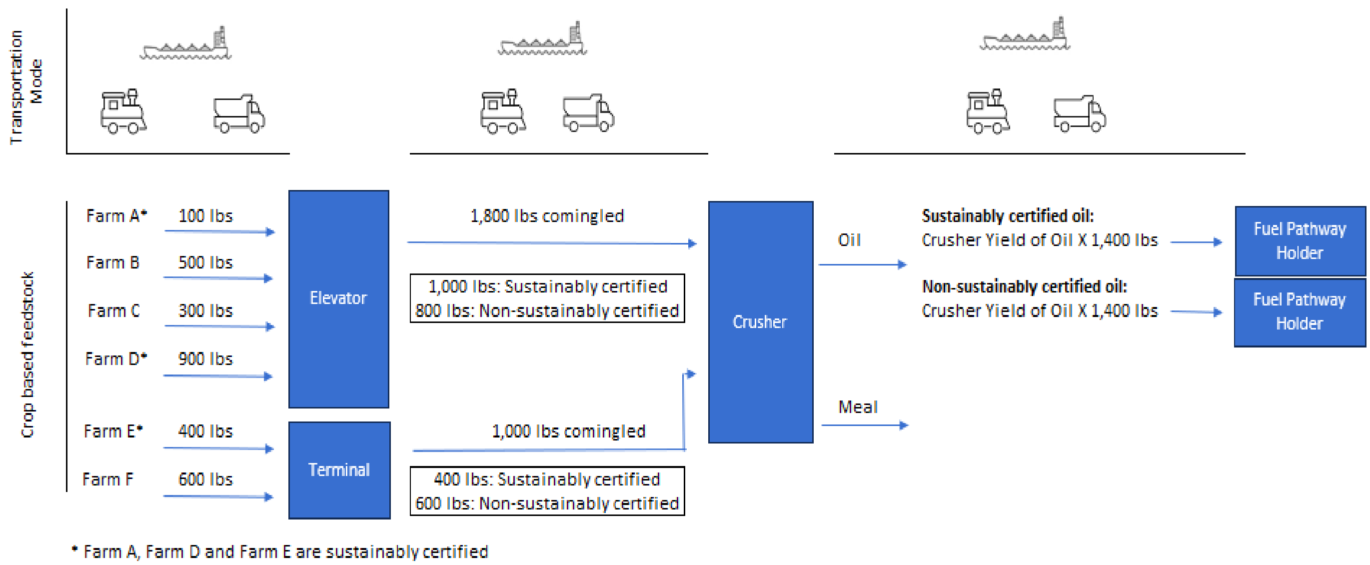
[3] CARB Appendix E Purpose and Rationale: 2024 rulemaking p80
[4] U.S. Soy Export Council International Buyers Guide

transportation emissions and inefficiencies adding cost to the production of renewable diesel and causing feedstock supply disruptions.

Simplified depiction of a material balance approach applied to the crop-based feedstock supply chain



As noted, the sustainability certification system does not go far enough to distinguish the carbon-reducing practices implemented by some farmers. This system merely acknowledges whether the feedstock can be used in a LCFS fuel pathway. Rather, a sustainability program should acknowledge when a farmer has implemented techniques to reduce the carbon emissions from crop production, which in turn is used to lower the carbon intensity of the renewable fuel. If CARB implements the third-party certification program, MPC recommends
217.5 including provisions that would allow a renewable fuel producer to take carbon intensity reduction credit for crop-based feedstocks grown using smart agricultural practices.

Renewable natural gas is needed to decarbonize the industrial sector, any additional limitations will slow the use of renewable natural gas in the industrial sector.

CARB recognizes renewable natural gas as a low carbon intensity fuel in its use as a feedstock to hydrogen production. CARB allows the use of book-and-claim accounting to connect the environmental attributes of renewable natural gas produced at one location to the use of natural gas in hydrogen production at another location. Book-and-claim accounting is vital to renewable natural gas production and growth as many renewable natural gas facilities are not located in the same geographic regions where the hydrogen facilities are located. Because book-and-claim accounting has been available, renewable natural gas production facilities continue to be built throughout the country and have not been isolated to locations near hydrogen production facilities, California or adjacent states. If CARB were to limit the ability of renewable natural gas producers to use book-and-claim accounting, CARB would slow the growth of renewable natural gas and its
217.6 use in industrial facilities producing fuels supplied to the California market. Marathon thus supports the continued use of book-and-claim accounting.

Adding attestation requirements to Specified Source Feedstocks is unnecessary.

217.7 MPC opposes the attestation requirement for specified source feedstocks. The attestation requirement would add significant and unnecessary verification workload to the annual verification process, as the chain-of-custody evidence is already reviewed and verified under the current regulatory provisions.

The specified source feedstock supply chain includes multiple entities, such as points of origin, collectors, aggregators, storage terminals and at times pre-treatment facilities. Each of these entities must provide an attestation stating a feedstock has not been altered from the pathway application. This requirement is problematic. A downstream entity within the supply chain likely lacks the knowledge of how a previous entity handled the feedstock, including whether it has undergone additional processing.

xxx.7 If CARB retains the attestation requirement, then CARB must do two things. First, CARB must narrow the attestation to information about the feedstock while the feedstock was in that attesting entity's control. An entity representative should not be required to attest to information of which he has no knowledge. Second, CARB must explain the energy systems that are included in CARB's emission factors. The existing default emission factor documentation[5] does not explain to entities within the supply chain what is included in

217.8 CARB's default values for feedstock collection, processing, and handling. Any activities not included in the default emission factors would be considered "additional processing" and thus should be identified in the attestation. Unless each entity understands the activities considered to be "additional processing," entities may not submit accurate attestations.

The jet fuel importer or producer should not be the First Fuel Reporting Entity.

217.9 MPC opposes assigning the producer or importer of jet fuel as the First Fuel Reporting Entity and strongly recommends the position holder of the fuel in the tanks at an airport be the First Fuel Reporting Entity. This would allow those closest to the use of the fuel, the airports, airlines, and position holders, to work together and determine the most appropriate accounting and tracking method for reporting fuels with an obligation.

CARB's proposal identifies that fossil jet fuel after 2028 will no longer be exempted from a compliance obligation unless it is used for interstate or international flights. To distinguish exempt jet fuel from obligated jet fuel, the proposed amendments require the First Fuel Reporting Entity to designate the obligated volumes of jet fuel as "Fossil Jet Fuel used for Intrastate Flight." The jet fuel producer or importer, however, does not know whether its volume of jet fuel is used for intrastate flights or is used for interstate and international flights. Unlike gasoline or diesel, which can be tracked to determine whether it is sold in state or out of state, jet fuel is delivered to airports, commingled within storage tanks, and used to fuel all flights at the airport. The fuel producer cannot track its jet fuel into the airplane and determine whether the fuel was used for intrastate, interstate, or international flights.

As additional explanation, the jet fuel logistics within California includes the transportation of jet fuel through pipelines and trucks to airport storage facilities. Jet fuel traveling on the pipeline is often commingled in breakout tankage along the pipeline before reaching its final destination at airport storage facilities. These airport storage facilities may be owned by one or more airlines. The jet fuel delivered into the storage facilities

[5] CA GREET 4.0

is commingled and may be used by any one of the airlines, who loads the fuel onto any one of many aircraft departing from an airport. Once jet fuel is placed in these airport storage facilities, only the airlines will know if the fuel was used for intrastate, interstate, or international flight. Placing that burden on the producer, who has no knowledge of how the fuel is ultimately used, will make compliance with the proposed regulation impractical, leading to the potential for inaccurate reporting. The position holder in the airport storage tanks is the appropriate party to report obligated intrastate jet fuel because it is closest to the fuel and its use.

The Refinery Investment Credit Provision is critical to incentivize petroleum refineries to reduce emissions.

Refineries are comprised of many complex, large scale industrial pieces of equipment that are not easily retrofit or optimized to reduce emissions from the production of transportation fuels. Many times, energy efficiency and emission reduction projects within refineries require large amounts of capital. The LCFS incentive provides additional support to move these projects forward. These same projects may provide additional benefits to the State by reducing nitrogen oxide (NOx) and other combustion emissions in largely disadvantaged communities, maintaining Union jobs, and supporting the local economies surrounding the refineries.

217.10 The proposed amendments sunset the Refinery Investment Credit Protocol in 2040. MPC opposes setting a date for the provision to end as projects that qualify for crediting will continue to provide benefits to the state long past 2040. Additionally, MPC recommends CARB remove the requirement that applications for process improvement projects under §95489(e)(3)(H)[6] be submitted on or before December 31, 2025, as it does little to incentivize innovation and reduce emissions within a petroleum refinery.

Recommendations on the proposed CA-GREET 4.0 and associated Tier 1 calculators.

217.11

- The process energy natural gas emission factor for the Tier 1 Simplified Calculator Hydroprocessed Ester and Fatty Acid Fuels[7] found in Tab "CA-GREET 4.0", cell E23 of 75,496 gCO_2e/MMBtu NG, LHV is greater than the same value calculated in CA-GREET 4.0. Summing the emissions found in CA-GREET 4.0, Tab "NG" for NG Extraction, NG Processing, NG Transport 680 miles pipeline, and the average of emissions for a Large Boiler and Small Boiler results in a NG emission factor of 74,788 gCO_2e/MMBtu. MPC recommends CARB review the process energy natural gas emission factor value found in the Tier 1 Simplified Calculator to ensure it is correct, if the value is correct MPC requests CARB detail the method it used to derive the value as MPC cannot replicate it using CA GREET4.0.

217.12

- The emission factor in CARB's proposed Tier 1 Simplified Calculator for Hydroprocessed Ester and Fatty Acid Fuels for Standard Value, US/Canadian Feedstocks, Animal Fat found on Tab "CA-GREET 4.0" cell E14 of 286 gCO_2e/lb includes a Residual Oil share of process fuels of 28.6%[8]. A 2022 publication in ACS[9] identified that in the U.S., rendering facilities have "phased out residual oils and replaced them with natural gas" resulting in substantial emission reductions. MPC

[6] CARB LCFS Proposed Changes, 45-day package
[7] Tier 1 Simplified Calculator Hydroprocessed Ester and Fatty Acid Fuels
[8] CA GREET 4.0 Tab "Bio oil" cell C64
[9] XU et all. ACS Publications 2022

recommends CARB use this work and decrease the Standard Value for US/Canadian Feedstocks, Animal Fat to capture the transition of U.S. rendering facilities away from Residual Oil to natural gas.

217.13
- The emission factor in CARB's proposed Tier 1 Simplified Calculator for Hydroprocessed Ester and Fatty Acid Fuels for Land Transport, Barge found on Tab "CA-GREET 4.0" cell E17 of 0.0212 gCO2e/lb-mile has doubled in comparison to the same emission factor found in CA-GREET 3.0. It appears CARB has accounted for backhaul emissions from the use of barges to transport renewable feedstocks and products. Barges themselves do not generate a significant amount of emissions as they do not have main engines that propel them through the water. Barges are either tethered to a tugboat or pushed by a tugboat when transporting cargo[10]. The 2022 Commercial Harbor Craft Regulation (CHC) includes a requirement that both tugboats and barges utilize renewable diesel while operating in California waters, or approximately 24 nautical miles from the California coastline. MPC recommends CARB discount the barge emission factor for the biogenic portion of CO_2 that is produced from the use of renewable diesel in CHC transporting renewable feedstocks and products within California waters. If CARB is not able to account for this in the Tier 1 Simplified calculators, MPC recommends CARB allow pathway applicants provide documentation that identifies the barge and tug utilized to transport renewable feedstocks within California waters that utilized renewable diesel.

Thank you for the opportunity to comment on these subjects. If you have any questions about anything discussed here, feel free to reach out to me at bcmcdonald@marathonpetroleum.com.

Sincerely,

Brian McDonald

RE: FuSE Comments on 2024 Rulemaking Proposed LCFS Amendments

Energy Mission Control, Inc. dba FuSE Carbon Technologies (FuSE) appreciates the opportunity to comment on the proposed Low Carbon Fuel Standard (LCFS) changes to the program. FuSE is a Sacramento-based technology company that helps facilitate participation in the LCFS, as well as in Oregon's Clean Fuels Program, Washington's Clean Fuel Standard, British Columbia's Low Carbon Fuel Standard, and the Canadian Clean Fuels Regulation for many hundreds of small, medium, and enterprise level businesses operating tens of thousands of electric vehicles and equipment in every qualified electricity reporting category. Building upon decades of clean-transportation industry and public funding experience, FuSE has developed a comprehensive and streamlined software platform that eliminates many of the administrative roadblocks that traditionally preclude small fleets from opting into clean fuel programs and allows them to take clear, affirmative, and immediate steps to reinvest in electrification efforts of their business operations.

We offer support, additional background on typical industry practice, information on the current state of affairs on electric off-road vehicle and equipment fleet participation, and a series of suggested alternatives or improvements on the current regulation language and amendment proposals:

218.1 **FuSE strongly supports the concept of the AAM, however, believes single-year or intra-year adjustments are technologically feasible and digestible to the market.** As currently proposed, and as the market has clearly identified via trading trends, the proposed updates to CI targets and infrequency of AAM triggering is not stringent enough.

218.2 **FuSE supports the amended text reflecting the transition of E_{XD} Displaced calculated values not applying to forklifts, and similarly should be expanded to fixed guideways.** Original intent and discussion of a model year threshold in both applications was tied to the implementation date of the LCFS program[1], the equipment's already deployed status, and not to the physical difference in equipment efficiencies across those model year threshold dates. The elimination of any model year association with technology deployments, especially as the LCFS program ages, makes less and less sense with newer technologies being deployed and streamlines the administrative work with submitting and reviewing applications greatly. There is no meaningful purpose for pre-2011 or post-2010 designations in these categories, or any others moving forward should new transportation equipment types be introduced in the future.

[1] https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/lcfs_meetings/12022016discussionpaper_electricity.pdf

FuSE

218.3 **e-Mission Control strongly opposes the EER reduction for forklifts under 12,000lb lift capacity, for three important reasons:**

1) This will **heavily undermine the success of the Zero-Emission Forklift Rule**, which uses the LCFS program funds, as currently calculated, to show a beneficial ROI. Reducing the EER by half increases the ROI by 50% or more, directly impacting small and medium-sized businesses that will be required to purchase new lifts and equipment to comply.

2) The **EER is not the place to account for market penetration effects of the LCFS program**. The purpose of the EER, the *Energy Economy Ratio*, is to define how much more energy efficient an alternative-fueled vehicle or equipment is relative to an internal combustion baseline. Making miscellaneous adjustments to the EER value implies that the same may happen to other vehicle or equipment categories as market penetration is increased, even if that is not the agency's current intent. **There already exists high market penetration of renewable diesel, electrified eOGVs/shore-power for container operations, and several other LCFS-qualified equipment segments. Cavalier EER adjustments set a bad precedent for future rulemaking, both in and outside of California.** If market penetration is a concern of LCFS staff, then a credit calculation variable should be introduced. Please be aware that **implementation of metering in the eMHE category will already reduce eMHE credit generation by 90%+ (most fleets will not see an ROI on submetering and Book-and-Claim ROI is not likely in the near term, meaning the reduced EER is impactful in the credit calculation equation twice).**

3) **Any tactic taken to reduce credit generation should only come from adjusting the compliance curve.** CARB has an unprecedented opportunity to move more and more capital from regulated entities to fleet electrification, with relatively very little argument from such regulated entities, and we believe any rollback of opportunity is simply a delaying of the overall GHG reduction opportunity in the transportation sector.

   As has long been established, the LCFS is meant to incentivize the adoption and use of low-, zero-, and negative-carbon fuels, and any policy within the program that facilitates this goal should be supported. FuSE currently represents many hundreds of small and medium-sized fleets, all of whom are operating some mix of equipment and vehicle types. For example, a small company may operate a few forklifts and a number of light-duty cars as part of their general operation. Simultaneously, a large company may operate hundreds of forklifts, thousands of refrigeration units, dozens of light and heavy-duty vehicles, several off-road pieces of equipment (i.e. yard trucks or rail car movers), and a host of other transportation technologies. In our experience, **none** are entirely zero-emission across their operation. The LCFS program should holistically support fleets of all types, mixes, and sizes, and, as there is no prohibition on spending funds generated from one technology (i.e. forklifts) on another (i.e. converting TRU's to hybrid eTRU's), CARB should continue incentivizing zero-emission technologies until **entire fleets, not specific technologies**, are entirely zero-emission.

Additionally, considering specific technologies for a reduced EER value simply based on the commercialization readiness or market penetration becomes an extremely slippery slope. In addition to forklifts, total cost of ownership analysis for light-duty vehicles[2], shore power[3], hybrid eTRUs[4], natural gas Class 8 trucks, and soon, heavy-duty vehicles[5], all regularly show a net benefit, even without incentive from the LCFS, and many will reach a significant market penetration well within the time bounds of the LCFS. The shore-power market penetration of container vessels subject to the At-Berth Regulation is over 90%, but eOGV is still an eligible category in the LCFS, as it should remain, so ports and port tenants can continue reinvesting in other technologies and other shore power verticals needing upgrades. This trend will continue as manufacturing becomes more effective, supplies become more readily available, and efficiencies and storage capacities increase substantially over the next five to ten years. We believe that the argument for reduced credit generation potential, if based on the concept of additionality (whereby a key decision maker would have made the decision to electrify a certain piece of equipment anyway, even without the LCFS), should be **fleet-focused**, and not equipment-focused. As mentioned above, being equipment-focused is a short-sighted perspective considering the volume and mix of equipment at any one company, and is entirely juxtaposed with the intention of the LCFS. For example, the question should not be, "Will a fleet operator purchase a forklift even without the LCFS value?" but instead should be, "Without the funds that an electric forklift would generate from the LCFS, would that fleet operator have upgraded vehicles or equipment on site that does not have a beneficial TCO?" If "No" is the response to the second question, then no equipment, regardless of commercialization, TCO, or market penetration should be excluded from the LCFS.

Also, while it is not in CARB's jurisdiction to consider other states or geographies developing clean fuel programs/standards, CARB should note that much of California's LCFS regulatory language is often heavily utilized in the deployment of other programs (i.e WA and OR both use much of the FSE definition, EER table values, and much more). In the same way that the localized emission reductions from out-of-state renewable fuels imported into the state are seen outside of California, CARB should consider the implications of regulatory change influencing other agencies considering the adoption or amendment of similar programs. Excluding technologies now will set a bad precedent, intentional or otherwise, for states that need to lean on the CARB LCFS regulatory language for success, and worse, heavily influence greenhouse gas emission reduction in areas that do not have wide adoption of electrified vehicles and equipment.

218.4 **Metering requirements for forklifts need to be phased in.** There is widespread agreement that metering for forklifts is a preferred method of reporting for credit generation, as it more closely aligns with other

[2] https://ww2.arb.ca.gov/sites/default/files/2020-06/190225tco_ADA.pdf
[3] https://theicct.org/sites/default/files/publications/ICCT-WCtr_ShorePower_201512a.pdf
[4] https://www.safeconnectsystems.com/the-ultimate-user-guide-to-etru/six-steps-to-convert-to-etru/ & https://www.mass.gov/doc/etru-grant-brochure/download
[5] https://ww2.arb.ca.gov/sites/default/files/2020-06/190225tco_ADA.pdf

reporting categories, is more accurate, and would eliminate an administrative burden related to registering and tracking equipment locations. However, as is also widely agreed, **the electric forklift technology evolution status is still very rudimentary,** with almost all deployed charging systems not having any integrated metering. To date, telematic deployments are still largely cost-prohibitive on a per-unit/battery level to be installed just for purposes of LCFS participation, have difficulty with data access and transfer within confined warehouse operations, and may not be appropriate across mixed OEM fleets. As "smarter" technologies are made more available by OEM's to give energy consumption insight to fleet operators, we believe a **phase-in schedule similar to the ZE Forklift Rule** is appropriate to accommodate for naturally-occurring turnover to new systems.

At only a 50% market adoption of electric forklifts, there is still a significant amount of equipment that needs to be transitioned to a zero-emission fuel source, especially considering that the overall electric market share has not changed in recent years. As mentioned in the paragraphs above, many of the companies we represent have mixed fleets and rely on the funds from their LCFS participation to expedite the continued conversion of their forklifts and to work towards full conversion of their on- and off-road fleets. FuSE supports the continued use of the Calculated Methodology used for forklift energy consumption, though technical revisions could be considered to ensure data accuracy and integrity.

218.5 **Regarding Third-Party Verification for the electricity provisions, FuSE supports extra visibility into data submissions as long as it avoids generating prohibitive burdens for small generators.** According to FSE-level registration data, aggregation service providers represent approximately 94% of electricity-provision-related FSEs participating in the LCFS, which we suspect is due largely to the burden of reporting and transaction activities. Specifically, the verification process should not be so burdensome as to prevent small generators from participating in the program, with or without an aggregator. FuSE encourages the ARB to further clarify the process of EV charging verification. In regards to site visits, program participants would benefit from understanding what information other than meter data would need to be verified. If the addition of verification increases participation costs, small fleets and/or aggregators may be prevented from helping small groups participate in the LCFS program. If verification
218.6 is expanded to include EV Charging transaction types (eTRU, eCHE, and eOGV Fueling, etc), FuSE would support an exemption for aggregators representing small volume generators, as there is no meaningful mechanical difference between an exempted small generator participating independently and a designator representing such a generator. The designator is simply facilitating the administration of the program and is likely to reduce the chance of reporting error.

218.7 **FuSE supports the inclusion of other equipment types, though we suggest CARB establish EER values for GSE and agriculture equipment.** During the July 7 workshop, CARB mentioned that staff is considering the inclusion or addition of zero-emission applications for rail, agricultural equipment, commercial harbor craft and airport GSE under the Tier 2 EER-adjusted CI pathway application process. We highlight that these application opportunities are already present under the current regulation and any pathway applicant may submit an EER-adjusted Tier 2 pathway application. Using other studies, such as the CAC's EER RFP[6], CARB should consider the additions of these equipment types to Table 5, significantly improving the likelihood of LCFS participation of these new technologies and would route badly needed funding toward fleets considering deployment.

218.8 **As proposed, modifications to the eMHE and eTRU credit ownership will NOT correct existing administrative issues.** Staff's intent is to award credit ownership to the fleet operator[7], however, as proposed, the credit ownership is awarded to the "FSE owner," with FSE defined as the "facility or location" and if, "there are multiple FSEs capable of measuring the electricity dispensed at the facility or location, then it is optional to provide serial number assigned to each equipment by the OEM and the name of OEM." This implies that if there are meters installed on site (which is regularly required in eMHE, eTRU, eOGV, and eCHE categories), then the ***meter*** owner becomes the credit generator. It is extremely common in leasing and renting arrangements that the charger ownership (and thereby the individualized meter, if available) be withheld by the lessor, and thereby the opportunity to assert ownership of credit generation remains, and worse, that double-counting occurs due to the lack of incentive of the meter owner to notify the FSE operator that credit generation is occurring. The electricity categories are fundamentally different from the liquid and gaseous fuel categories, and FuSE strongly suggests that CARB clarify that the FSE **operator** be the eligible credit generator in all electrification categories.

218.9 **"Private MHD-FCI charging site" is defined in the amendments, but no subsequent regulatory language is proposed.** The ISOR is clear that there is intent of supporting private MHD infrastructure, but no language is proposed. FuSE supports clarifying language identifying the opportunity for Private MHD-FCI crediting.

FuSE thanks CARB for the opportunity to comment and participate in the amendment process and looks forward to working with the LCFS team on future improvements that facilitate the transition of California's transportation fuel pool toward a more sustainable and decarbonized future.

Sincerely,

Energy Mission Control, Inc. dba FuSE Carbon Technologies

Chair Liane Randolph and Members of the Board California Air Resources Board
1001 I St.
Sacramento, CA 95814

RE: Prairie Farms Dairy Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

Prairie Farms appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). Prairie Farms are a farmer-owned cooperative. This means we are owned and operated by over 600 farm families who are critical members of society. They have selflessly taken on the tremendous task of producing nutritious, high-quality milk for a growing population, which requires being on the job 24/7, 365 days a year. We have represented American agriculture since our founding in 1938. Many of our dairy farms are operated by several generations of family members with roots dating back to the 1800s. On average, each farm milks around 120 cows and everyone pitches in to keep them happy and healthy - which means around-the-clock care

Prairie Farms applauds the leadership the California Air Resources Board (CARB) is taking on climate change and appreciates being a part of this important dialogue surrounding potential changes to the Low Carbon Fuel Standard (LCFS). The dairy industry has answered the call to action and is embracing environmental responsibility - from family farms in California, to farms across America. By installing and utilizing biogas systems, farms are offering practical solutions to the challenges CARB seeks to address.

With our support of CARB and the LCFS in mind, Prairie Farms would like to offer the following suggestions for improving the proposed amendments to the Low Carbon Fuel Standard:

Strengthening Carbon Intensity (CI) Targets

219.1a
219.1b

Prairie Farms applauds CARB and is encouraged to see that the proposed amendments aim to set more ambitious carbon intensity targets. A strong CI reduction target is a critical component for driving down (GHG) emissions in the transportation sector, reducing reliance on petroleum fuels, and transitioning to electric vehicles where feasible. However, we believe that there is both room and a need to go further. Using the numbers from CARB's Quarterly Summary Report and averaging the rate of credit growth over the past five available quarters, it shows that the current scale-up in the production of clean fuels will continue to generate low carbon fuel standard credits with the cumulative bank likely eclipsing 25 million by the end of 2024.[1] The proposed increase in stringency falls short of what the market can deliver, and as a result, is missing an opportunity to deliver millions of additional tons of reductions in greenhouse gas emissions called for in statute and further underscored in the update to the state's Scoping Plan as approved by the Board in December 2022.

Prairie Farms believes that there are two key adjustments that CARB can make to the stringency as part of the 15-day change process that do not require new economic or environmental analysis as they fall within the scope of the work CARB has already included in the Initial Statement of Reasons (ISOR), specifically, by increasing the step-down as well as pulling forward the effective date for triggering the Auto Acceleration Mechanism (AAM) CARB can "recapture" reductions in GHG emissions that will otherwise be lost with the current proposal. Doing so will also send a clear, and supportive market signal to continue investments in clean fuels that would otherwise be constrained and subdued by the current proposal.

Avoided Emission Crediting

219.2

The proposed amendments seek to phase out avoided emission pathways for projects that break ground after December 31, 2029, for biomethane used as a transportation fuel through 2040 and for biomethane used to produce hydrogen through 2045. Prairie Farms believes that this is inconsistent with the incentive-based approach outlined in SB 1383 and currently being implemented in California. Moreover, eliminating or phasing out the avoided methane crediting in the dairy sector would lead to an inability to meet the state's targeted methane reduction goals and result in significant dairy methane emissions leakage. Avoided methane crediting is a key component of dairy methane reduction incentives that has achieved significant reductions

[1] California Air Resources Board, LCFS Data Dashboard Figure 3 – Quarterly Summary Report. https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard

to date and as stated previously, is one of the most effective tools to meet California's GHG goals.

According to a UC Davis analysis:

> . . . misguided efforts to change course by forced coercion to pasture-based operations, direct regulation of dairy farms, or limitation on dairy digesters incentives will not only fail to achieve the desired greenhouse gas emissions reductions but will exacerbate the problem by causing significant emissions leakage. Revenue streams that incentivize investment in biogas capture and beneficial use are critical. Phasing out of avoided methane crediting in the dairy sector would jeopardize existing projects, making them uneconomic in the long-term, and dry up investment capital for the additional digester projects sought by CARB to achieve the state's ambitious and aggressive targets.[2]

Avoided methane emissions are a critical part of science-based, life cycle assessments, and their inclusion in carbon intensity scores are consistent with internationally recognized standards of carbon accounting. The scientific evidence for this is robust and recognizes that the baseline includes methane emissions that would otherwise be released into the atmosphere. Recognizing methane and its role as a short-lived climate pollutant, while incentivizing its removal from the atmosphere, has proven highly successful in supporting the reduction of millions of metric tons of carbon dioxide equivalents. We strongly encourage CARB to continue its longstanding commitment to a science-driven framework that utilizes proven science including Argonne National Laboratory's GREET model.

Book-and-Claim and Deliverability Requirements

219.3

Book-and-Claim has allowed the LCFS to evolve by supporting investments in clean fuels that have helped the program remain one of the most influential and successful transportation decarbonization policies in the country. To date, CARB's approach to indirect accounting in the program has been pivotal to its success, including its principles of driving greenhouse gas emissions down, facilitating investments and production of clean fuels, and in supporting increased clean fuel options for consumers.

It remains to be seen if and how the proposed deliverability requirements can be harmonized with the California Public Utilities Commission SB 1440 program, as suggested. It has been clear over the past year that CARB was exploring potential deliverability requirements. However,

---

[2] Kebreab, Ermias, Ph.D., Mitloehner, Frank, Ph.D., and Sumner, Daniel A., Ph.D., Meeting the Call: California is Pioneering a Pathway to Significant Dairy Methane Reduction (December 2022), available at: https://clear.ucdavis.edu/news/new-report-california-pioneering-pathway-significant-dairy-methane-reduction

throughout that process an actionable plan outlining the strategy and evidence necessary for imposing delivery requirements never emerged. Rather, stakeholders continued to raise concerns about the lack of a feasible plan which continues with the ambiguity of proposed amendments. Therefore, Prairie Farms recommends that the deliverability requirement language be removed from the current amendments to allow for further stakeholder engagement to support a clear and actionable plan for consideration in a subsequent rulemaking.

219.4 **True-up Provisions**

The proposal includes true-up provisions where verified operational CI's are drawn on to potentially adjust the credits based on certified CI's. The proposal indicates that a shortfall (i.e., a verified operational CI that is higher than the certified CI upon which project credits were generated) is subject to a "penalty" that is 4 times the spread for the applicable volume of fuel. The rationale for a 4X spread is unclear as a smaller spread (e.g., 2X) serves as a significant disincentive to producers for being overconfident in their analysis. Further, the language indicates that in the event the operationally verified CI is lower than the certified CI (i.e., it failed to generate as many credits as it could have) the Executive Offer (EO) "may" make the appropriate adjustment (true-up) by awarding additional credits to the applicable fuel reporting entity. The word "may" should be deleted. If the operationally verified CI, including an affirmative verification statement, is lower than the certified CI that was the basis for credit generation, the EO "must" award the supplemental credits supported by the underlying documentation.

The concept of adjustment to credits based on operationally verified CI's is sound. However, limiting the proposal to certified CI's is a significant oversight. The proposal must be carried over and applied to temporary and provisional CI's as fuel providers may rely on these CI's for months, or even years, as more refined pathways are evaluated and subsequently approved by CARB.

Temporary CI's have been an important option under the program, but applicants can be reluctant to use them given the heavy credit discount relative to facility-specific provisional CI's. Correcting for any under (or over) crediting while a temporary CI is used will help streamline and simplify the program as well as send a stronger signal to the market that investments in clean low-CI fuels will be rewarded. Further, including temporary CI's as part of the true-up process will reduce the pressure on CARB from developers to process LCFS applications quickly which has been an ongoing and growing challenge under the program. The concept of adjusting the awarding of credits based on operationally verified CI's is a key principle that supports innovation and must be reflected from project initiation, where a temporary CI is used, throughout the project's lifetime to properly account for and reward the associated reductions in greenhouse gas emissions. Credits should be awarded based on real-world operational experience and therefore adjusted accordingly when the temporary CI which is applied understates the benefits.

New Markets

219.5

As the technology in the transportation sector continues to evolve and advance towards lower carbon alternatives, Prairie Farms members and the rest of the dairy industry and are ready to serve these new markets, such as alternative jet fuel (AJF), low-CI hydrogen, as well as exploring opportunities where biomethane can be utilized outside of transportation. As these markets continue to grow, Prairie Farms asks CARB to remain mindful of the success of the historical framework of the program and to continue to apply it to these newer pathways and technologies, including the use of avoided emissions and book-and-claim.

Conclusion

Over the past year and a half, CARB staff have held numerous public workshops to gather feedback on potential changes to the program, and Prairie Farms is pleased to see that the rulemaking is nearing completion. Prairie Farms would like to underscore the importance of concluding this rulemaking as soon as possible. Any further delay to the rulemaking diminishes the necessary signal the market needs to facilitate and encourage continued investments in clean fuels. To continue the significant and unprecedented progress made by CARB and the dairy industry of California under the guidance and support of the CDFA, Prairie Farms urges CARB staff and the Board to finalize this rulemaking no later than the end of Q2 2024.

Thank you for the opportunity to comment on the proposed amendments, and we look forward to engaging with CARB staff on these topics.

Sincerely,

Samantha Bourke

Re: Proposed Low Carbon Fuel Standard Amendments

Transportation Fuels Branch Chief Lozo:

We appreciate the opportunity to comment on the California Air Resources Board's (CARB) Proposed Low Carbon Fuel Standard Amendments issued on December 19, 2023.

Corteva Agriscience is a U.S.-based global company entirely focused on agriculture. Founded on nearly a century of breeding and scientific expertise, we develop innovative seed and crop protection products and services with the goal of helping farmers maximize productivity, drive profitability, and enhance sustainability, while also equipping them to provide consumers with a wider range of safe, healthy and nutritious food options. These products are also critical components to a resilient agricultural system that enables food and energy security.

220.1 In the process of its review of proposed amendments to the Low Carbon Fuel Standard, we encourage CARB to consider two key points:

1) **Recognize existing and proven certification programs for sustainable biofuels production, rather than creating additional traceability requirements, which could create undue regulatory burdens on individual farmers.** U.S. farmers successfully participate in a variety of existing programs validating the use of biofuel production methods that meet international commercial and regulatory standards. Programs include the U.S. Soybean Export Council's Soy Sustainability Assurance Protocol, the National Cotton Council's Cotton Trust Protocol, and the U.S Grains Council's Corn Sustainability Assurance Protocol, among others. The certifications provided by these programs are increasingly sought by international buyers who wish to ensure sustainably sourced, deforestation-free inputs for their food, fiber, and fuel needs.

220.2

2) **Similarly, as CARB works to refine land-use and environmental models for biomass-based feedstock, ensure the use of the most up-to-date datasets that reflect the latest sustainable farming practices.** Farmers have made significant gains in yield and productivity over the years, resulting in consistently higher yields on the same or fewer acres, with less carbon intensive inputs. This progress should be reflected in current modeling.

We are committed to working side-by-side with farmers in the U.S. and around the world to deliver expertise and innovative products that support more sustainable and productive farming, whether the crops are used for feed, food, fiber, or fuel. We support farmers with training and tools to help them incorporate the latest advances and technology into their daily operations. Around the world and across all product portfolios, our experienced Corteva agronomy, product, sales, and R&D team members provide a variety of educational opportunities to farmers both in person and online. With a deep commitment to transparency, these efforts focus on sharing the latest information, technologies, best practices and product innovations to help farmers find ways to improve soil health, nutrient and water stewardship, and productivity that are right for their unique, local needs.

An example of a way we're providing the latest sustainable innovations to farmers is our proprietary winter canola seed adapted for the Southern U.S. environment. Together, with Bunge and Chevron Renewable Energy Group, we are working to develop the necessary seed and processing supply chain to support the production of renewable diesel and sustainable aviation fuel. The resulting fuel is compatible with existing combustion engines and will provide a more sustainable option for aviation and diesel fleets. Importantly, it will also support farmers as they work to address some of the world's most pressing challenges, including the energy transition, climate change and food security. Farmers can increase their income potential while prioritizing the sustainability of their operation by reducing greenhouse gas emissions and ensuring land coverage year-round.

Once again, we appreciate the opportunity to comment on the Proposed Low Carbon Fuel Standard Amendments and look forward to supporting your efforts to implement an effective LCFS program.

Sincerely,

Kendall Palmer
Senior Director and Growth Leader, Biofuels
Corteva Agriscience

February 20, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 Low Carbon Fuel Standard (LCFS) Amendments

Dear California Air Resources Board,

Braya Renewable Fuels (Newfoundland) LP ("Braya") is the owner of the Come By Chance refinery in Newfoundland, Canada. Braya recently completed the conversion of the idled conventional oil refinery to renewable diesel and sustainable aviation fuel production. The refinery is strategically located to source a variety of low-carbon intensity feedstocks and deliver fuels to various end markets, including California, to help meet LCFS demand and California's broader greenhouse gas initiatives. Renewable diesel and sustainable aviation fuels help decarbonize sectors—heavy transport and aviation—that are key to economic activity and have few other near-term, executable decarbonization solutions.

CARB's successful LCFS program has attracted global attention and has inspired other states and nations with its market-based principles, scientific basis, and feedstock- and technology-neutral approach. The LCFS has exceeded expectations, is over-performing, and is becoming increasingly diverse in approaches that serve to reduce and replace fossil fuels as part of its decarbonization efforts. The LCFS has made meaningful investments in low-carbon fuels a reality - Braya's conversion of a conventional crude oil refinery to biofuels is a perfect example of achieving that goal.

We appreciate the opportunity to provide the feedback you requested in advance of the recently postponed Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments. We also have new evidence and data in support of the previous workshops conducted over the course of 2022 and 2023.

221.1 **Braya Opposes Artificial Cap on Vegetable Oil Feedstocks**

As presented in our previous comments in response to the November 9, 2022 and February 22, 2023 workshops, a number of studies have concluded that lipid-based feedstocks for biofuels do not impact food resources or cause deforestation and damaging land conversion. At present, crop-based feedstocks are needed to spur continued growth and investment in renewable diesel and sustainable aviation fuels, which are key solutions for decarbonizing the heavy transport and aviation sectors for the foreseeable future.

In our response submitted in December 2022, we provided evidence and a study conducted in November 2021 by LMC International and commissioned by the Advanced Biofuels Association (ABFA), identifying global lipid demand from all sources and all end-users and the fact that the current crop-based feedstock supply exceeds biofuels' forecast demand through 2030 while still meeting the demand for non-biofuel use. Further, the study assumed a maximum use of lipid-based feedstock for biofuels even though advances are being made regarding the use of wastes, starches, algae, and biomass, which will provide alternative feedstock supplies and naturally lower the demand for crop-based biofuels. The summary slides and 2030 conclusions can be found here: https://advancedbiofuelsassociation.com/study-shows-available-advanced-biofuels-feedstocks-can-pace-biofuel-demand-through-2030/ .

Following the February 2023 workshop, Braya submitted additional relevant data in our responses submitted in March 2023, utilizing the same scientific approach and presenting a Short-Term Outlook through 2025 developed by LMC in February 2023 (the "Report") in response to an updated request by the ABFA. The study identifies a number of events that have occurred globally and have positively impacted the amount of available crop-based and lipid feedstocks. To summarize, and as set forth in the Report, the supply of fats, oils, and greases (FOG), as well as soybean and canola have all increased and will continue to do so at no detriment to increased global demand or at the expense of the environment or society due to land use change. The Report is located in Appendix 1 on Page 11 of the ABFA's response to the EPA Set Rule on its website at the following location: https://advancedbiofuelsassociation.com/wp-content/uploads/2023/02/ABFA-2023-Set-Rule-Comments-Final.pdf

We re-emphasize that time and investment are still needed to continue growing the supply of second-
221.8 generation biofuels. The efforts are underway, but the continued support of the LCFS will help make this goal a reality. To date, the LCFS has maintained an unbiased, technology-neutral approach, allowing the program to evolve naturally, without picking winners and losers, which has been a key to CARB's success. CARB already has a stringent and ongoing review process in place to address indirect land use change ("iLUC") applicable to biofuel incentives. This mechanism significantly penalizes producers that utilize crop-based feedstocks by elevating CI scores well above those of non-crop-based feedstocks. A prohibition on crop-based feedstocks will increase costs across the board, including to end-use consumers, and stifle investment in the vital expansion of renewable diesel and sustainable aviation fuel supply that would otherwise continue as CARB continues to work toward its electrification goals.

Braya supports and appreciates CARB's efforts to support low-carbon fuel production and distribution. We commend CARB for understanding the impact of unnecessarily and prematurely eliminating a much-needed source of feedstocks that can readily meet the LCFS's objectives, specifically regarding medium to heavy transport and aviation biofuels, as there are currently no viable alternatives available on a scale to meet California's goals. We also note that the LCFS structure is effective in reducing the relative share of crop-based biofuels to the overall mix of biofuels to the extent such fuels do not represent significant carbon intensity reductions. Notably, crop-based biofuels represent about 60 percent (60%) of liquid biofuels (discounting natural gas, hydrogen, and electricity) in the years 2021 to 2023 according to the most recent LCFS Quarterly Data Spreadsheet available through the end of the third quarter of 2023. Indeed, these same crop-based fuels represented roughly 75 percent (75%) of the contribution to the success of the LCFS during the years of 2011 to 2021. Many other sources of feedstock are limited in quantity or can be difficult to trace back to the source and are, therefore, not used at large. Advances in technology and feedstocks are being realized as evidenced by the declining relative share of crop-based fuels, but it will take time to generate significant volumes of these feedstocks as electric initiatives come to fruition. In the meantime, crop-based biofuels are critical to meeting the near-term needs of the market and to continue reducing the carbon intensity of fuels in industries that are notoriously difficult to decarbonize.

221.2 **Braya Supports Emission Factor Updates**

The global agriculture industry has made significant investments in improved farming practices, feedstock processing and decreased emissions at the biofuels facility level over the past decade. Paradoxically, the current CA-GREET3.0 model does not account for or reward these substantial improvements. Additionally, the current CA-GREET3.0 model lacks key customization features such as not providing for specific vessel sizes (instead using wide ranges) and electricity mixes that are not representative of the various regions feeding into the LCFS. CARB has proposed to use an updated calculator CA-GREET4.0, in conjunction with the release of the new amendments, but much of the data is still woefully out of date. Specifically, the "Land Use Change" values for soy and canola oil remain unchanged at 29.1 and 14.5, respectively, as both calculators are based on a now decade-old GTAP-BIO model.

In June 2023, Floyd Vergara, former Chief and Assistant Chief in the Industrial Strategies Division and Research Division at CARB, overseeing the development of the LCFS, submitted public comments to CARB on behalf of Clean Fuels Alliance America (CFAA) and California Advanced Biofuels Alliance (CABA) in response to the May 31 and June 1, 2023, Low Carbon Fuel Standard Virtual Community Meetings: Clean Fuels CABA Comments CA LCFS EJ Community Meetings May-June 2023. The evidence provided by Mr. Vergara uses the most recent updates to the Argonne National Laboratory calculators and GTAP modeling by Purdue in 2023 and conclusively shows that the iLUC scores being used by CARB in both the CA-GREET3.0 and CA-GREET4.0 models are grossly inaccurate and unfairly punitive to crop-based biofuels. Notable findings include:

- 2023 Purdue estimates for soy iLUC are at 9.78 gCO_2e/MJ, compared to CARB's 29.1 gCO_2e/MJ.
- Purdue used 4x the shock volume of 3.22 billion gallons in 2023 to achieve the 9.78 gCO_2e/MJ.
- Accordingly, CARB's iLUC score of 29.1 for 800 million gallons is more than three times higher than the score that would result from using newer, more accurate evidence and methodologies.

We recommend updating the model used by CARB to reflect this more current and accurate data by reviewing Argonne and Purdue University's most recent releases. Such an update would also negate the age-old argument that a cap on crop-based biofuels is needed. Regenerative agriculture and superior agronomic practices are being adopted globally. Many countries, including Argentina, have been using these practices for decades on farmland that has been in place since at least the 1980s as shown by a number of studies, including the Organisation for Economic Co-operation and Development's (OECD) paper, Agricultural Policies in Argentina. Additionally, CARB benefits from the United States Renewable Fuel Standard (U.S. RFS) structure that requires evidence that crop-based feedstock must not be grown on land that was placed into production after December 19, 2007 as defined at 40CFR Part 80 §80.2 under "renewable biomass," exceeding the requirements under the LCFS.

Finally, we support Mr. Vergara's assertion that the use of biomass-based diesel is a significant positive factor in the health of citizens located in EJ communities given that drop-in biofuels reduce diesel particulate matter by up to 80% in older engines as shown in the CARB Assessment of the Emissions from the Use of Biodiesel as a Motor Vehicle Fuel in California "Biodiesel Characterization and NOx Mitigation Study." As additional support, the CFAA engaged Trinity Consultants to prepare a number of Health Effects Studies for CARB on the positive impacts of using drop-in biomass-based diesel in place of petroleum diesel. Of note are the "immediate community health improvements that can be measured in reduced medical costs and health care burdens" and estimates that switching to biomass-based diesel could result in the prevention of "over 900 premature deaths per year, hundreds of thousands of asthma cases reduced or avoided per year, and reducing over 100,000 work loss days per year, totaling $7 billion dollars per year in avoided health costs."

221.3 **Braya Supports Credit True-Ups for Temporary Pathways**

Braya applauds CARB for moving forward with the credit true-up for Tier 1 and Tier 2 pathways and is supportive of implementing a credit true-up for temporary pathways. Temporary pathways are inherently conservative CI scores; the longer a producer's facility-specific CIs are under review, the greater the expected loss of revenue that can be so vital at the start of operations. A true-up based on facility-specific production data will not only support new biofuel producers but will also provide more accurate data for CARB to measure the program's success in decreasing GHG emissions.

Similar to many other producers, Braya is constantly evaluating further capital projects to increase efficiencies and lower emissions. A true-up that would allow credit generators to be rewarded for reducing their CI scores over time would encourage these proactive and environmentally friendly projects.

221.8 Finally, we believe that CARB should synchronize efforts with other agencies to utilize data and precedents to streamline processes. Doing so would be of significant value, both to increase access to new pathways/new producers and reduce burdens on CARB's resources and staff. For example, the EPA has a number of approved pathways based on GREET modeling for national and global feedstocks. CARB should explore whether these pathways could be leveraged to establish a wider range of temporary pathways that could be used until facility-specific pathways (based on operational data) are fully available.

221.4 **Braya Supports CARB's Continued Advancement of the Standards**

Understanding that 30% under Alternative B is what CARB has identified as the basis on which to move forward with the current proposed rulemaking, Braya remains optimistic and in support of Alternative C, under CARB's Compliance Target Options, as discussed during the November 9, 2022 workshop. With standards based on achieving a 35% reduction in carbon intensity by 2030, Alternative C is the only option that truly advances CARB's efforts by making rational use of currently available and efficient
221.4a biofuels while incentivizing new technologies that are being developed. Further, under Alternative C there would be no cap on crop-based feedstocks, allowing the program to set more aggressive and beneficial targets. During the February 2023 workshop, CARB presented Alternative B as the base case for discussions, citing that a majority of stakeholders were in support of at least a 30% CI reduction based on comments received in December 2022. However, during the lengthy Q&A to follow, a majority of stakeholders providing input appeared to be in strong support of a 35% target, and Braya agrees. We hope that the supporting data we are providing as evidence, in addition to expanded support from other stakeholders will assist CARB in making the decision to move forward with a 35% target without artificially capping beneficial feedstock supply.

Also during the November workshop, CARB presented the possibility of devising a "Self-adjusting CI target mechanism" that would trigger an auto-adjustment in standards. We believe that this concept has merit, assuming that it would spur credit bank drawdown and stop plummeting prices when LCFS
221.4b credits are being over-generated. We were pleased to see this mechanism's adoption in the currently proposed rulemaking. However, we would like to see this much-needed mechanism implemented earlier than currently proposed. Without such a mechanism, producers who have made responsible investments in reliance on a functioning incentive-based LCFS program will face grave economic uncertainty. Braya also supports front-loading the new CI targets to further repair the currently significantly depressed credit prices. We look forward to CARB moving forward with both provisions.

221.5 **Braya Supports Streamlining and Updating the Application and Review Process for Pathway Approval**

By updating and improving the existing Lookup Table and Tier 1 calculators in addition to adding new and/or separate Tier 1 calculators, CARB will be able to focus attention on critical new feedstock sources, availability, and supply, as well as new technologies, thereby expediting approvals for new Tier 2 pathways. Braya truly appreciates all the effort the CARB staff have put into this daunting endeavor.

221.6 **Braya Supports an LCFS Verification Body Firm Rotation Alternative for CPA Firms**

Due to the increased federal and state regulatory oversight inherent in the nature of a licensed CPA firm, we suggest verification bodies that are also CPA firms not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation every six (6) consecutive years. We have found it increasingly difficult to identify alternate qualified verification bodies under the current system.

221.7 **Braya Supports Less Intensive LCFS Verifications**

CARB staff's current proposal includes a provision allowing less intensive verifications solely for electricity used as transportation fuel by permitting verification bodies to skip site visits so long as they have visited the site within the last two (2) years and have issued a positive verification statement. CARB's rationale included:

- "[T]here is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits."
- "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years."
- "This should reduce the cost of verification services which is often passed on to program participants."

We wholly agree with CARB's statements above and believe it should apply to all validations and annual verifications for any reporting entities. In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies. We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers that are then passed on to program participants. Finally, we acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions already include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you in advance for taking the time to review our comments and solutions concerning these very important issues. We look forward to working with CARB and welcome any opportunities to discuss further and provide any additional assistance and insight.

Respectfully,

Jennifer M. LeRow
Director of Regulatory Compliance
Braya Renewable Fuels (Newfoundland) LP

Subject	Opposition to allowing fossil fuels + CCS to extend past 2040 phase-out
Comment	Please find a letter attached and signed by nearly 50 groups expressing their strong opposition to the proposed LCFS amendment that would allow petroleum projects using carbon capture and storage (CCS) to continue to generate credits beyond the phase-out date of December 31, 2040. This amendment creates a dangerous loophole that relies on a so-called climate solution that is anything but; the result will be California incentivizing and perpetuating the climate catastrophe and the health and environmental harms that come with it.

Re: Opposition to Proposed LCFS Amendment Loophole to Allow Petroleum Projects with Carbon Capture & Storage Past the 2040 Phase-out

222.1 (cont.)

The undersigned groups write to express their strong opposition to the proposed Low Carbon Fuel Standard (LCFS) amendment that would allow petroleum projects using carbon capture and storage (CCS) to continue to generate credits beyond the phase-out date of December 31, 2040.[1] This amendment creates a dangerous loophole that relies on a so-called climate solution that is anything but; the result will be California incentivizing and perpetuating the climate catastrophe and the health and environmental harms that come with it.

Evidence and real-world experience do not support CARB's apparent belief that CCS eliminates the problems of fossil fuel extraction, refining, processing, and use. Many of the signatories to this letter have submitted comments to CARB time and time again with information making this clear. Further, it is untrue that Intergovernmental Panel on Climate Change (IPCC) pathways require CCS to meet climate goals. What is needed is a just and rapid transition away from fossil fuel use;[2] CCS is a way to avoid that truth.

As recently said by Massachusetts Institute of Technology professor Dr. Charles Harvey (who himself once started a CCS company, before abandoning it upon realizing the technology simply fails): **every dollar spent on CCS is a waste** because it allows "for the continued production of oil and natural gas at a time when the world should be ending its dependence on fossil fuels." [3] As Dr. Harvey aptly notes: "Instead of spreading doubt about climate science, the industry now spreads false confidence about how we can continue to burn fossil fuels."[4] We see just that glaring problem in the proposed petroleum loophole.

Addressing the climate crisis requires resources, leadership, and courage. We have no time to waste. **CARB must act courageously and reject the proposed petroleum phase-out loophole.**

RE: Air Liquide Comments regarding the Proposed Low Carbon Fuel Standard Program

Dear CARB Staff:

On behalf of Air Liquide, thank you for the opportunity to submit our comments regarding the proposed changes to the Low Carbon Fuel Standard Program.

A world leader in gases, technologies and services for industry and health, Air Liquide has a presence in all 50 states, employing more than 20,000 people in the U.S. at more than 1,400 locations and plant facilities, offering industrial gases and related services to customers in a range of industries, including oil and gas, chemicals, steel, construction, food and beverage, research and analysis, electronics, and healthcare. Hydrogen has been, and continues to be a core growth area for our business in the U.S.

Air Liquide has more than 60 years of expertise across the entire hydrogen value chain. From production and storage to distribution and the development of applications for end users, Air Liquide is focused on hydrogen as a key molecule for investment, research, and technology development. Air Liquide is a global leader in clean hydrogen development and has made significant investments worldwide, exceeding more than $1 billion dollars invested in hydrogen in the U.S. and has a commitment to invest an additional $10 billion dollars globally in low-carbon hydrogen by 2035.

The LCFS regulations are among the most effective and influential regulations governing clean transportation fuels. In order to make the program as effective as possible and in order to ensure that the goals of the State of California with respect to implementation of zero emission vehicles and supporting infrastructure are met, we have the following recommendations:

223.1 **Carbon Intensity Benchmarks and Market Stabilization:** We believe the extension of the Carbon Intensity Benchmarks to 2045 and the "automatic acceleration mechanism" or "ratchet" that would advance the benchmark to the next year's target will prove to be an effective tool in managing the state's clean fuels targets. These benchmarks will help assure that by 2045 all fossil fuels, and also many alternative fuels, would generate deficits for almost all of the greenhouse gases that they create. The proposed mechanisms will also have the potential to strengthen the LCFS credit market. Low credit values have been a significant hindrance to investments, especially in the development of the much needed hydrogen refueling infrastructure. We are supportive of these and other actions needed to stabilize the credit market.

Hydrogen Refueling Infrastructure Credits. The LCFS currently provides credits for the unused capacity of hydrogen fueling stations that service light-duty vehicles and as proposed, its expansion to heavy duty vehicles.

> Heavy Duty Vehicle Program - The Heavy duty vehicle market represents both one of the largest emitters of carbon and particulates and one of the most difficult to abate sectors. Hydrogen fuel

cell vehicles now being made available to the market provide an ideal solution to address these challenges provided there is sufficient infrastructure and low carbon, low-cost, reliable hydrogen production and supply. The proposed expansion of the HRI credits to include Heavy Duty
223.2 stations will provide a mechanism to encourage this infrastructure investment and we are strongly supportive of the proposed program introduction.

Light Duty Vehicle Program - Expanding the light-duty (LD) Hydrogen Refueling Infrastructure (HRI) capacity is imperative. This is particularly crucial to accommodate the unique needs of medium-duty (MD) vehicles, given their co-mingling with LD fleets. The alignment of LCFS capacity credits with market behavior is paramount for station crediting. To support this,
223.3 maintaining the existing 1200kg credit is recommended, considering its success in driving private sector investment. This credit has proven effective in supporting the existing HRI, and its continuation is aligned with the ongoing success of the infrastructure.

Station Location Limitations To enhance the viability of hydrogen refueling stations, flexibility in
223.4 locations for both HD and LD is paramount. The current absence of a comprehensive station network argues against stringent geographic limitations. These limitations have the immediate consequence of limiting decarbonization and air quality impacts of transitioning from fossil fuels, especially in the overburdened communities along these statewide transportation corridors.

Inequity in Capacity Crediting Standards We suggest that the requirement of 80% renewable content requirement exclusively for HRI should be eliminated as it is unnecessary and counter to
223.5 the carbon intensity focus and technology-neutral principles that have driven innovation and investment in the LCFS program to date. The requirement will reduce available supply, increase the cost of H2 thereby hindering adoption and achievement of the state's zero carbon goals. The imposition of an 80% renewable content requirement exclusively for HRI raises concerns in comparison to Fast-Charging Infrastructure which will place hydrogen at a competitive disadvantage to other energy sources, electricity in particular, which benefit from substantial federal, state, and ratepayer subsidies not extended to hydrogen.

Biomethane. We are aligned with CARB's continued acknowledgment of the importance of methane reduction to address Global Climate Change and that the responsible use of RNG as a feedstock to hydrogen production can be a strong proponent of methane reductions regardless of the sourced location. We strongly support the changes in regulatory language which provide visibility to the eligibility
223.6 of RNG as a feedstock for extended years, a necessary step in our investment in these technology and energy sources. We make the following additional recommendations:

Deliverability Language The creation of barriers to prevent the importation of RNG into California markets or for use as a feedstock in both in-state and out-of-state production of fuels should not be adopted. RNG is physically interchangeable with fossil natural gas and can be distributed in the same natural gas pipeline networks across the US. This established distribution network provides a proven, national distribution network that should be leveraged, not restricted in the deployment of low carbon fuels. The 50% flow requirement is arbitrary and unjustified.

Landfill Methane Recognition of the methane avoidance of projects diverting organic material from Landfills should be revisited and expanded. The ability to increase methane capture rates through landfill RNG projects should be included.

RNG Power Sourcing Renewable natural gas facilities need flexibility to source renewable power as an input to RNG production in order to further incentivize the carbon reduction potential in its acquisition.

Book-and-Claim Accounting for Process Electricity. The expansion of the book-and-claim accounting for process energy will provide strong incentive to hydrogen producers to seek low-carbon alternatives in process energy to further reduce their process carbon intensities. To best take advantage of this proposed change we recommend the following:

223.7 Expansion to all process energy The opportunity to incentivize carbon reduction in process energy exists for all sources of energy. We recommend that the process energy allowance be expanded to include all energy sources used in production including such sources as the fuel used for thermochemical conversion energy.

Clarification on delivery The regulation reads as follows:

The low-CI electricity must be supplied to the grid within the local balancing authority where the electricity is consumed or delivered to that local balancing authority consistent with the requirements of California Public Utilities Code section 399.16, subdivision (b)(1).

CPUC Section 399.16(b)(1) requires delivery to ***California***, which makes this provision ambiguous. Presumably, the proposed amendment is intended to require delivery only to a "local balancing authority," even if outside of California, but it could be interpreted to require delivery to California. We recommend the wording be updated to ensure delivery to an end use such as hydrogen production, outside of California is included.

Sourcing from new production The proposal requires that Low-CI electricity must come from new or expanded electricity production (after January 1, 2022, or within three years of the start of the hydrogen production facility, whichever is later.) This is an overly restrictive requirement that burdens hydrogen production, disadvantages it to other electricity usage, and has not been shown to provide benefits in a regulated electricity market that includes significant grid renewables and a Renewable Portfolio Standard. We recommend the elimination of this requirement.

223.8 **Book-and-Claim Accounting for Low-CI Hydrogen.** The proposed amendments allow book-and-claim accounting for low-CI hydrogen injected into a pipeline. We recommend that this allowance include not only hydrogen used as a transportation fuel but also for hydrogen used as a feedstock to produce other low-CI fuels. Substituting low-CI hydrogen in these production processes can be one of the most effective mechanisms to improve the environmental footprint of traditional fossil fuel production, SAF, and renewable diesel. Including these uses in the eligible accounting for hydrogen provides a strong incentive for these producers to reduce their product CI.

We appreciate CARB staff's work on the development of the proposed rule and their commitment to improving the LCFS. Successful adoption of battery and fuel cell electric vehicle technologies requires changes in LCFS to reinforce market pricing, parity in policy, and encourage deployment of fueling and charging infrastructure for zero-emission fleets. Thank you for the opportunity to provide input to this critically important program. If you have any questions or comments, please contact me at any time.

Sincerely,

David P. Edwards, PhD

RE: ChargePoint Comments on Proposed Low Carbon Fuel Standard Amendments

Thank you for the opportunity to submit comments on the proposed amendments to the Low Carbon Fuel Standard (LCFS) issued on December 19, 2023. ChargePoint has reviewed the Proposed Regulation Order and appreciates the work of the California Air Resources Board (CARB) Staff to implement changes to LCFS that will advance investment in low carbon fuels and infrastructure in California.

About ChargePoint

Since 2007, ChargePoint has been committed to making it easy for businesses and drivers to go electric with one of the largest electric vehicle (EV) charging networks and a comprehensive portfolio of charging solutions. ChargePoint's cloud subscription platform and software defined charging hardware is designed internally and includes options for every charging scenario from home and multifamily to workplace, parking, hospitality, retail, corridor, and fleets of all kinds.

Summary of comments

224.1
- Expand the scope of "less intensive verification" for on-road electricity crediting to allow for networked charging stations that meet certain requirements to be pre-approved. Entities that do not meet the requirements for less intensive verification could still undergo full verification.

224.2
- Remove the exemption for dedicated parking spaces under multifamily crediting and allow owner/operators to claim credits on all stations at multifamily locations.

224.3
- Regarding the MHD-FCI provision: (1) relax the siting requirement to within 5 mi of a FHAA corridor, (2) reduce the minimum kW nameplate capacity to 200, (3) consider shortening the FCI crediting window to 7 years, and (4) roll unutilized LD-FCI capacity into the MHD-FCI provision to increase deployments.

224.4
- Take greater action to stabilize the credit market, either through supply-side intervention or more stringent carbon intensity targets. Increase the step down to 10%.

224.5
- Modify the Automatic Acceleration Mechanism (AAM) formula to trigger once the credit bank exceeds three-fifths of the prior year's deficits, instead of three-fourths.

Requirements for less intensive verification

The inclusion of on-road electricity crediting in the verification program is not a small lift and needs to be done thoughtfully. Therefore, we suggest CARB consider putting off including electricity verification in this rulemaking given the many other issues being considered. However, if CARB believes that on-road electricity reports must undergo third-party verification under the amended regulation due to largescale risk of misreporting (which to our knowledge, there is currently no evidence of), CARB should lean on existing technology, standards and relevant regulations when designing verification. To that end, we appreciate CARB's inclusion of a "less intensive verification" pathway in the proposed rules but believe that this does not go far enough. The less intensive verification pathway should be expanded to consider the following:

The EV charging network is fundamentally different than the traditional point-source liquid fuel supply network: whereas liquid fuels originate from fewer and larger sources (refineries), EV charging stations are significantly more disaggregated, where each point (or charger) in the network represents a small amount of potential fuel supply which renders physical site visits across the whole network impractical and costly. For meter accuracy assurance, CARB should instead lean on accuracy thresholds that already exist in the industry, such as those within the California Type Evaluation Program (CTEP), which require that level 2 (L2) EV charging meters meet an accuracy threshold of ±1% upon manufacturing and calibration and ±2% over its useful life, while level 3 (L3) meters must meet a ±2.5% accuracy upon manufacturing and calibration and ±5% over its useful life. The CTEP standard is already being utilized by the California Division of Measurement Standards (DMS), the entity tasked with ensuring the accuracy of commercial devices, including EV charging stations. DMS sets standards to promote fair competition and ensure consumer protection and points to the CTEP as the metrological accuracy standard that chargers installed after a certain date must meet to be used for commercial purposes. County Weights & Measures offices, under the guidance of statewide rules established by DMS, serve to enforce the standards by conducting periodic site visits to verify the accuracy of fueling stations.

Recommendation: CARB should pre-approve charging stations that meet CTEP's meter accuracy standards for participation under the less intensive verification pathway.

Pre-approval would mean exempting eligible charging station models from site visits and third-party meter testing based on that model's meter accuracy substantiation. CARB could publish a list of exempt charging station models that meet CTEP's meter accuracy standards for credit generators' reference. This is similar to the approach taken under Canada's national Clean Fuels Regulation. Otherwise, the existence of the DMS framework for assessing and enforcing charger accuracy would render additional site visits and meter testing, even only in half of the years as currently proposed under the "less intensive verification" pathway, under the LCFS program duplicative and punitive on the industry, particularly for small owner/operators[1].

With assurances around charging station meter accuracy ensured by the accuracy standards embedded in CTEP, the final step to less intensive verification would be a "desktop" review of the data in the reports. The scope of the desktop review would be to ensure that the data in the quarterly reports submitted through the LRT matches the data that was output from the charging network. EV charging networks are underpinned by extremely accurate (down to the watt-hour), real-time data in a way that traditional liquid fuel networks are not[2]. Networked EV charging provides a near constant stream of data that can be verified against reported charging activity.

There are a number of standards, practices, technologies and processes charging network operators adhere to to ensure the accuracy of data. For example, ChargePoint complies with several standards to ensure that the data reported by the station maintains its accuracy as it is transferred from the station to the cloud, and that any data anomalies are detected and removed before being reported. Many network operators also maintain compliance with Payment Card Industry Data Security Standards (PCI DSS) to ensure an accurate and secure environment for network transaction data. CARB could pre-approve networks that meet certain standards for use under the less intensive verification pathway, similar to pre-approving charging station models based on meter accuracy. Standards and documents required for pre-approval could include SOC2 reports and/or PCI certification.

Our recommendations for the less intensive verification pathway are not necessarily meant to be prescriptive, but rather to point out how existing technologies, best practices, and standards already widely adopted in the industry should be incorporated into the pathway. This will greatly minimize administrative costs for an industry that is still scaling. This is also the general approach taken under Canada's national program. We urge CARB to not try and reinvent the wheel re: on-road electricity verification. Reporting entities that do not meet the requirements for less intensive verification would still be able to undergo full verification.

Credits for non-residential chargers at multi-family residential properties.

ChargePoint strongly supports the proposal to allow FSE owners to generate credits for stations installed at multifamily properties. This change will create more revenue opportunities for property owners that install chargers at multifamily locations, and

[1] The cost of a non-streamlined verification will be disproportionately significant to small owner/operators since LCFS revenues will be smaller. In multifamily residential settings, physical site visits will be particularly challenging due to privacy concerns.
[2] Some charging networks are more robust and secure than others and we recommend some level of minimum thresholds in order to qualify for the less intensive verification pathway, as we touch on below.

critically, incentivize more deployment of chargers for residents of multifamily homes, a market segment that has historically lacked investment.

Recommendation: remove the exemption for dedicated parking spaces and allow owner/operators to claim credits at all multifamily locations.

While we fully support the proposal to treat multifamily crediting the same as non-residential, we do not agree with the proposal to treat chargers in dedicated parking spaces differently. Not only will the exclusion of restricted parking spaces be extremely difficult to track, but it also arbitrarily distinguishes credit generation based on a residence's parking arrangement. Recent analysis by the CEC indicates that expanding the range of charging options available in the parking lots of multifamily housing will ensure charging is not a barrier to EV adoption.[3] Increasing home charger access for residents of multifamily homes must be a priority to equitably meet the routine charging needs of more EV drivers, and for this reason, we strongly support this change by CARB.

Residents of multifamily housing are generally not able to install conventional home charging without financial assistance from the building owner. This is because charger installation at multi-family properties often requires upgrades to shared electrical panels and running conduit across common parking areas. A single household of a multifamily residence is generally unable or unwilling to shoulder the high cost of charger installation themselves. In other words, there is a "split incentive" affecting multifamily properties in which a property owner must pay for and organize installation, while the chargers may only benefit the fraction of residents who drive EVs at the time of the upgrade.

In fact, there is a case to be made that chargers in dedicated multifamily residential parking places may have the most impact on those residents switching to electric and should therefore be supported by the LCFS through the ability to generate value from credit generation. This is especially true considering CARB's proposal to redirect funds from the Clean Fuel Reward (CFR) program towards MHD EVs (which we also strongly support). Whereas before, CFR value was generated by residential (including multifamily) charging so it made sense to return some of that value to individual EV drivers via LD EV rebates. If CFR value will now go towards MHD EV rebates, it only seems right to allow owner/operators of multifamily chargers to retain the value of the LCFS which can help finance or buy down the cost of the station.

<u>**Medium and heavy duty (MHD) Fast Charging Infrastructure (FCI) credits**</u>

ChargePoint strongly supports the addition of the MHD FCI provision. While the passage of the Advanced Clean Fleets and Advanced Clean Trucks regulations are expected to create greater demand for MHD EVs, infrastructure development to support these vehicles remains

---

[3] California Energy Commission, Assembly Bill 2127 Electric Vehicle Charging Infrastructure Assessment ("AB2127 Report") at 48.

economically challenging due to the lack of MHD vehicles on the road today and the expectation that it will take time for the market to grow. The expansion of FCI credits for both private and shared MHD FCI is a much-needed intervention to commercialize charging infrastructure and help stimulate investment for this segment. ChargePoint also appreciates the inclusion of shared private fleet chargers in this program. Nonetheless, a few revisions to the rules for MHD FCI credits will allow the program to support the nascent MHD refueling market more effectively.

Charging hubs for MHD vehicles are likely to require several megawatts of power for each site. These projects will in most cases require significant distribution grid upgrades by the utility. Due to the complex factors that inform site selection for MHD charging sites, including but not limited to access to travel corridors, proximity to vehicle routes, distribution grid capacity, and land acquisition, it remains unclear which locations will be the most efficient to locate private or shared MHD charging hubs. For this reason, overly narrow location requirements for MHD FCI sites may impede development by eliminating projects that would otherwise be ideal due to ample grid capacity. While we understand CARB's intent for the FCI program to focus charger deployment in alternative fuel corridors for the purposes of accessibility and equity, station owners and drivers would benefit from less stringent geographic limitation.

Recommendation: relax the geographic siting requirement to 5 mi from a FHAA fuel corridor to provide flexibility for site selection.

The amendment proposal establishes a minimum power level of 250 kW for chargers serving sites that receive MHD FCI credits. The minimum power level established for MHD-FCI sites should consider *today's* MHD fleet needs, as well as the anticipated needs of the future. For most MD vehicles on the road today, 200 kW is more than sufficient for the vehicle's needs and helps lower overall system costs (relative to 250 kW or greater). Therefore, ChargePoint recommends that CARB reduce the minimum power level for each charger serving MHD FCI to 200 kW, as this minimum is sufficient to meet the market where it is today, as well as accommodate the needs of coming MHD vehicles.

Recommendation: reduce the minimum kW eligibility requirement to 200 from 250.

Regarding the MHD-FCI crediting window, while some sites will need a 10-year window to recoup capital costs, a longer window could encourage overbuilding and disincentivize utilization in the short to mid-term, both of which are not ideal for the market. We believe a crediting window closer to 7 years will suffice for the majority of projects and encourage sites to build for utilization sooner rather than later. This should also free up more capacity under the MHD-FCI cap sooner which will open up capacity for more sites over time.

Recommendation: consider shortening the MHD-FCI crediting window to 7 years.

The CEC reports that as of 2023, California has over 9,000 DCFC ports in operation and is ahead of schedule to meet its port deployment target of 10,000 ports by 2025.[4] ChargePoint believes LD FCI revenue has successfully accelerated investment in the market for public DCFC and is partly responsible for the state's success in this segment. When paired with the continued growth of LD EV sales in California, it seems clear that continued investment in LD-FCI can sustain itself without greater support from FCI credits. By contrast, the MHD segment would benefit from greater FCI support because it is underdeveloped relative to the state's goals. The CEC estimates that by 2030, California's 155,000 MHD EVs will need about 114,500 public and shared chargers.[5]

To further accelerate the market for MHD electrification, **we recommend CARB rollover any unused LD-FCI credits into the MHD cap to allow for greater investment/deployments in this segment (more on this below)**.

Revised Clean Fuel Reward Program

ChargePoint supports the proposal to redirect funds from the CFR program to make MHD EVs more cost-effective. The current framework of allocating CFR funds towards LD EV rebates has long since lost efficacy as the rebate amount is not salient to prospective EV drivers to the point where it induces additional purchases. ChargePoint is pleased to see this change as the current state of the MHD EV market is more in need of funding than the LD segment.

Light duty FCI credits

The proposed regulation establishes a transition plan to reduce FCI crediting available for LD DCFC applicants. Among other changes, the proposal amends the cap for LD FCI credits to 0.5% of prior quarter deficits, a reduction from the previous cap of 2.5%. ChargePoint supports this change and agrees that LD-FCI credits should be capped to no more than 0.5% to focus infrastructure crediting on the more nascent MHD EV market. As discussed previously, ChargePoint believes MHD-FCI should be the priority and recommends CARB consider further reduction in the availability of LD-FCI credits in favor of a higher cap on MHD-FCI credits.

Should the LD-FCI pathway remain open beyond 2025, ChargePoint believes it would be premature to limit eligibility to stations with a nameplate capacity of 150 kW or more in light of the other proposed changes to the pathway. A station capacity minimum of 150 kW combined with the change to how FCI charging capacity is calculated as well as the extension of the crediting timeline to 10 years will together incentivize overbuilding sites without regard to utilization solely because of FCI credits.

[5] AB2127 Report at 2.

New carbon intensity benchmarks

In the weeks following CARB's release of its amendment package in mid-December, the spot market for credit prices declined ~20% (falling from $70/credit to a low of $57/credit). In that time, the market incorporated CARB's proposal of a 30% carbon intensity (CI) target by 2030, along with the proposed changes to the supply side, and determined that this market will continue to be oversupplied. Without more ambitious CI targets and/or clearer steps to curb biofuel production with uncertain greenhouse gas benefits (Murphy & Wook, 2024)[6], it is apparent that this market will continue to be oversupplied and credit prices will remain low for the foreseeable future.

In prior conversations with CARB staff, we have come away with the understanding that CARB assumes the LCFS program, and the potential revenue it affords, does not factor into investment decisions for EV project operators (fleets, charging operators, etc.) and therefore investment in EVs and charging infrastructure is agnostic to LCFS credit prices. We do not agree with this assumption. Advanced Clean Cars, Advanced Clean Trucks, and Advanced Clean Fleets do not directly address or fund charging infrastructure. The LCFS program can, and often does, provide an important revenue stream for EV project operators and can be the difference between a project penciling or not. Project developers, operators, and investors in the EV space operate similarly as those in other spaces: they evaluate all available costs and revenues when assessing a potential project and often make decisions based on expected net cashflows. The difference between expected 5-year LCFS revenues on a L2 station with roughly average utilization in a world where credit prices hover in the ~$60/credit range vs ~$150/credit is significant. In the former, expected 5-yr LCFS revenues do not amount to enough to influence the business case, whereas in the latter, LCFS revenues offset a significant portion of the cost of the station and can even be leveraged for project financing.

As electrification has the most potential for long-term deep decarbonization of transportation, we urge CARB to account for the impact that sustained low credit prices may have on transportation electrification investments. Without clearer steps to limit crop-based biofuels – or specific carve outs for on-road electricity credits, like how some state Renewable Portfolio Standards set specific carve outs for solar – investments in charging infrastructure and electric fleets will be crowded out under the program by the continued surplus of biofuel credits in the market.

[6] Murphy, Colin & Ro, Jin Wook. Updated Fuel Portfolio Scenario Modeling to Inform 2024 Low Carbon Fuel Standard Rulemaking (Draft). University of California Davis Policy Institute for Energy, Environment, and Economy.

Recommendation: in lieu of some sort of cap on crop-based biofuels, we believe the 2030 CI target needs to be increased to 32.5% to 35% and the stepdown needs to be increased to 10% to raise price expectations to the level needed to usher in more investment.

Automatic Acceleration Mechanism (AAM)

ChargePoint supports the proposal to establish the AAM but recommends that CARB make the mechanism stronger. As proposed, the AAM would not have been triggered in any of the years after the 2018 amendments. These years include 2022, a year when the credit market price declined by ~50%.[7] The AAM should be designed specifically to counteract this type of negative price movement, so a mechanism that would not have reacted in 2022 is not strong enough.

To strengthen the mechanism, we recommend that ARB amend the first condition of the AAM to be reached when the cumulative credit bank is greater than three-fifths of the deficits generated over the same calendar year rather than the current condition set at three-fourths. With this update the AAM would have been triggered in 2022 but not any of the other years following the 2018 amendments. Since these other years saw price increases or modest declines, the new threshold suggests a balanced mechanism that reacts only to large price decreases.

Conclusion

ChargePoint appreciates the opportunity to submit comments to CARB on the Proposed Regulation. We stand ready to work with CARB Staff to implement the changes discussed in these comments, particularly to ensure that the process of verification is administratively efficient for the on-road charging market.

Respectfully,

Evan Neyland

HiiROC response to:
Staff Report: Initial Statement of Reasons, dated December 19, 2023,
'Proposed Amendments to the Low Carbon Fuel Standard'

Thank you for the opportunity to respond to this document and thereby provide comments in relation to the proposed revisions to California's Low Carbon Fuel Standard (LCFS). We welcome California's efforts to reduce greenhouse gas emissions to date and recognise the critical role that the LCFS is playing both in addressing climate change and improving air quality.

We fully support the objective of increasing the stringency of the LCFS program in reducing emissions and decarbonising the transportation fuel sector – in our view the proposals represent an effective means of doing so. We welcome the additional support the proposals create for the hydrogen sector, which will help it to play a full and meaningful role in achieving the aims of the Standard. However, we strongly urge that the proposals should take into account the fact that new pathways for the production of hydrogen at scale will soon be commercially available.

In particular, our own Thermal Plasma Electrolysis (TPE) process offers a route to hydrogen production at point of use which combines the low carbon dioxide footprint of water electrolysis with the low electricity input requirements of steam methane reforming. TPE does this by stripping the carbon from a wide range of hydrocarbon feedstocks, capturing the carbon as an inert solid, and producing low-carbon hydrogen fuel (with no CO_2 emissions created by the process itself).

1. About HiiROC (www.hiiroc.com)

HiiROC, a UK-based company, is developing its Thermal Plasma Electrolysis (TPE) process to produce low-cost, low-CO_2 hydrogen, at a comparable cost to steam methane reforming but without emissions from production and using only one-fifth of the electricity required by water electrolysis.

HiiROC's proprietary technology uses plasma torches to convert gaseous hydrocarbon feedstocks (such as biomethane/ renewable natural gas, flare and industrial waste gases, propane, and natural gas) into low carbon hydrogen and solid, high-quality carbon black. The latter co-product is stable and could simply be disposed of, but it also has existing and emerging end-use applications, ranging from tyres and inks to building materials and soil enhancement. Using our TPE process, hydrogen can be produced where it is needed, utilising existing energy infrastructure, and reducing hydrogen storage and transportation costs.

Our technology is rapidly approaching full commercial deployment, bringing with it the potential to unlock step-change growth in the hydrogen economy around the world.

2. Why are we responding to these proposals?

The California Air Resources Board (CARB) has been clear that hydrogen has a significant role to play in delivering the decarbonisation of transport in California and the LCFS is intended to provide economic incentives to produce hydrogen and thereby displace fossil transportation fuels. The proposals have also highlighted the need to incentivise greater production of clean fuels needed in the future, such as low-carbon hydrogen.

At HiiROC we are committed to delivering the potential for TPE to decarbonise economic activity, diversify production pathways for low-carbon hydrogen and enable the global energy transition that will be required to counter anthropogenic climate change.

Responding to these proposals represents a critical way for us to keep policymakers and regulators informed about the technological advances that we believe will enable delivery of low carbon hydrogen at greater scale and at lower cost than existing alternatives. In particular, we wish to highlight that low-carbon hydrogen can be produced without the generation of process CO_2 emissions, by splitting hydrocarbon feedstocks into hydrogen and solid carbon, and that outputting solid carbon in this way should be treated as equivalent to the storage and capture of gaseous CO_2.

We note that the UK's Low Carbon Hydrogen Standard (LCHS) has recently been amended to recognise this equivalency, with 'Gas splitting producing Solid Carbon' having been added as a production pathway falling within scope.[1]

We hope that our thoughts will be helpful and would welcome the opportunity to discuss them further.

3. Comments about: the key concepts underpinning the regulatory update proposal (page 4)

225.1
- *Increasing the stringency of the program to reduce emissions and decarbonize the transportation fuel sector, which will also aggressively reduce our dependence on fossil fuels*
  - We support the aim of increasing the stringency of the program, given the anticipated impacts of reducing emissions and decarbonizing the transportation fuel sector.
- *Strengthening the program's equity provisions to promote investment in disadvantaged, low income and rural communities*
  - In this context, we note that our TPE technology is modular, can be sized to meet local demand and can be deployed to produce hydrogen at point of use. This means that 225.2 there is significant flexibility in where investment in the technology is deployed, with the potential for 100% of any units installed in California to be sourced and manufactured in the United States.
  - TPE also draws on different supply chains from other low carbon hydrogen production technologies, minimising delivery risk for California's hydrogen economy and enabling a broader spread of investment.
- *Supporting electric and hydrogen truck refuelling*
  - 225.3 In this context, we note that our TPE technology is modular, can be sized to meet local demand and can be deployed to produce hydrogen at point of use. TPE is also capable of producing hydrogen on a flexible basis; this means it can deliver hydrogen volumes in

[1] https://www.gov.uk/government/publications/uk-low-carbon-hydrogen-standard-emissions-reporting-and-sustainability-criteria : UK Low Carbon Hydrogen Standard, version 3 – Appendix A, A.18 – A.26. The current treatment of Solid Carbon Sequestration is covered in the accompanying Data Annex, DA.53 – DA.55.

response to demand patterns. This makes it particularly suitable for the production of hydrogen at truck refuelling stations.

- *Incentivizing more production of clean fuels needed in the future, such as low-carbon hydrogen*
    - 225.4 We continue to view low-carbon hydrogen as a key enabler of an effective energy transition. What is important here is the carbon intensity of the hydrogen that is produced, not the production method itself. We strongly advocate for a regulatory framework that is technology-agnostic, providing a level playing field for the full range of production pathways which can satisfactorily deliver low-carbon hydrogen. This will best enable the emergence of price competition, which should in turn deliver a successful energy transition at least cost to consumers.
    - In particular, regulations need to recognise that producing solid carbon from hydrocarbons is an effective way of sequestering that carbon content. See Section 4 below for more specific discussion on this point.
- *Supporting methane emissions reductions and deploying biomethane for best uses across transportation*
    - We believe that deployment of our TPE technology at scale has a number of benefits from the perspective of methane emissions reduction.
        1. 225.5 Flare gas (i.e. natural gas associated with oil production which is combusted or simply vented to the atmosphere at the point of extraction, rather than being processed for onward use) can be used as a feedstock for the TPE process. Producing hydrogen on site from such flare gas, which would otherwise be flared or even vented directly to the atmosphere, has significant potential to reduce the methane and/or CO_2 emissions arising from the production of oil and gas.
        2. Conversion of methane into hydrogen at the site of oil and gas production also potentially reduces the need to transport methane, reducing the risk of methane emissions through leakage during transportation.
    - We would also argue that the best/most impactful use of biomethane is in the delivery of negative CO_2e emissions. When biomethane/renewable natural gas is used as the feedstock for the TPE process, this offers the capacity for negative emissions to be generated in the production of hydrogen, as the carbon content of the renewable feedstock is being fully captured. We believe that biomethane volumes should be prioritized for utilization in this way, delivering negative CO_2e emissions as well as hydrogen which can be used for transport applications.
- *Strengthening guardrails on crop-based fuels to prevent deforestation or other potential adverse impacts*
    - 225.6 We support the application of strong verification procedures for all low-carbon fuels, as we believe this is crucial to maintain public confidence in the robust credentials of those fuels.

4. **<u>Comments about: 'Allow Indirect Accounting for Low Carbon Intensity Injected into Hydrogen Pipelines physically connected to California and Expansion of Indirect Accounting for Low Carbon Intensity Electricity for Hydrogen Utilized as a Transportation Fuel'</u>** <u>(page 34)</u>

We note that the 2022 Scoping Plan Update calls for a significant increase in the production of low-carbon hydrogen, displacing fossil fuels for transportation.

HiiROC's TPE technology, by offering significantly lower electricity consumption compared to water electrolysis (approximately one-fifth), will allow far greater hydrogen production volumes from upstream energy infrastructure investment – including renewable electricity generation capacity. This opens the prospect of reaching California's decarbonization targets sooner and/or at a lower cost, with less major infrastructure investment required. For this reason, we believe (as highlighted earlier) that the regulatory framework needs to adopt a technology-agnostic approach which will allow all hydrogen production pathways to compete on a level playing field.

We fully support the adoption of "*book-and-claim of low-CI hydrogen to support the 2022 Scoping Plan update energy transition by overcoming bottlenecks in hydrogen production and supply*". We believe this will offer significant encouragement to what remains a nascent market today, by providing critical flexibility in matching supply and demand.

However, we are particularly concerned about the following proposal:

225.7 "*Staff is proposing to exclude hydrogen derived from fossil gas from book-and-claim eligibility unless low CI hydrogen is produced using book and claim of biomethane or with CCS and used as a transportation fuel.*"

We strongly urge that the output of solid carbon when producing hydrogen from hydrocarbons should be recognised as fully equivalent to CCS as a means of mitigating emissions of gaseous CO_2.

Carbon capture is inherently part of HiiROC's TPE process – the carbon content of the hydrocarbon feedstock is turned into solid, inert carbon. At no point in the process is CO_2 formed; for this reason, we wish to see the definition of CCS extended, such that it does not require CO_2 to be formed and then captured in order to qualify, and the outputting of solid carbon explicitly recognised as equivalent to CCS.

As we have noted above, biomethane can be used as a feedstock for the TPE process. Coupling this renewable feedstock with CCS, in the form of outputting solid carbon, presents the opportunity to deliver negative CO_2e emissions, which we contend will be an extremely valuable tool in countering anthropogenic climate change.

Once again, on behalf of HiiROC, I would like to thank you for the opportunity to comment on these important issues. Please do not hesitate to get in touch should any of the matters raised above require clarification.

Yours sincerely,

DJ Coneybeare

Board Comments Home

February 20, 2024
To: California Air Resources Board (CARB)

Re: Joint Comments on Proposed Low Carbon Fuel Standard Amendments
Submitted via CARB's online Comment Submittal Form

On behalf of Clean Air Task Force (CATF) and Pacific Environment, we are pleased to submit comments on CARB's proposed amendments to California's Low Carbon Fuel Standard (LCFS). We greatly appreciate the tremendous amount of work and transparency the CARB staff have invested in considering strengthening the LCFS 2030 targets, recommending new targets out to 2045, and proposing the important step of eliminating the current aviation fuel exemption for intrastate fossil jet fuel from the standard. However, as we and other have groups communicated with Chair Randolph[1] and as elaborated on by CARB staff at the February 22, 2023, workshop[2], without adequate safeguards, these measures pose significant and unacceptable risks of rapidly driving up demand for crop-based biofuels with several potential negative consequences. Such consequences include increased lifecycle greenhouse emissions from direct and indirect land use changes, as well as disruptions to food markets and natural ecosystems.

Pursuant to the California Global Warming Solutions Act of 2006, CARB must "adopt greenhouse gas ...emissions reduction measures by regulation to achieve the maximum technologically feasible and cost-effective reductions in greenhouse gas emissions in furtherance of achieving the statewide greenhouse gas emissions limit."[3] The California Legislature strengthened this directive in the California Climate Crisis Act, which provides that it is the "policy of the state" to "[a]chieve net zero greenhouse gas emissions as soon as possible, but no later than 2045, and to achieve and maintain net negative greenhouse gas emissions thereafter."[4] CARB recognized in adopting the LCFS that the goal of the regulation is to "reduce the full fuel-cycle, carbon intensity of the transportation fuel pool used in California."[5] Without adequate safeguards limiting the rapid growth in demand for crop-oil based biofuels, the current LCFS proposal could result in an increase in lifecycle greenhouse emissions due to direct and indirect land use changes. This would not "effectuate the purpose of" the above statutes.[6]

---

[1] Environmental Defense Fund, Clean Air Task Force and World Wildlife Fund-US letter to Chair Liane Randolph, May 5, 2023.
[2] Low Carbon Fuel Standard Public Workshop: Potential Regulation Amendment Concepts, February 22, 2023
[3] Cal Health & Saf. Code § 38562(a); see also id. § 38550 (directing CARB to establish a greenhouse gas emissions limit to be achieved by 2020).
[4] Cal Health & Saf. Code § 38562.2(c).
[5] 17 C.C.R. 95480.
[6] See Cal. Gov. Code § 11350(b)(1); see also id. (CARB's regulation must be supported by "substantial evidence" to demonstrate that it is "reasonably necessary to effectuate" the purpose of its enabling statutes).

Instead, such an outcome would go against the express goals of the LCFS and would frustrate California's mandate to reduce greenhouse gas emissions and effectively address climate change.[7]

While CATF is submitting separate comments on other aspects of the proposed amendments, these joint comments focus on the risks that the LCFS, if amended as proposed, will result in unsustainable consumption of vegetable oil-based biofuels and undermine the emission-reduction goals of the program.

In particular:

- Without adequate safeguards, strengthening and extending LCFS carbon intensity benchmarks will likely accelerate the rapid growth in demand for bio-oil based biofuels, directly and indirectly impacting food markets and increasing emissions from land use changes;
- 226.2 Including intrastate fossil jet fuel in the LCFS is an important policy signal for decarbonizing the aviation sector, but the current proposal will further increase demand for bio-oil based fuels, given that refining and hydrotreating bio-oils is currently the only commercially viable alternative to fossil jet fuel at scale; and
- 226.3 The only proposed sustainability requirement for crop-based biofuels is third-party certification that the feedstocks are derived from land that has not been forested since 2008, which is too narrowly scoped to serve as an effective constraint on climate-damaging land use change.

Given these risks, we make the following recommendations:

1. CARB should limit the volume of first-generation vegetable oil-based fuels that are eligible to generate credits under the LCFS program;
2. CARB should assess on an annual basis the direct and indirect market impacts from fuels obligated under the proposed sustainability requirements; and,
3. CARB should extend the sustainability requirements beyond crop oils to used cooking oil (UCO) and waste oils.

The Proposed Amendments to California's Low Carbon Fuel Standard Regulation[8] are likely to further accelerate the already growing demand for crop-oil based biofuels.

While our groups support CARB's intention to strengthen the LCFS' targets the lack of adequate safeguards or limitations on crop-oil feedstocks used in producing diesel and aviation fuel will further accelerate an already unsustainable growth in demand for crop-oil feedstocks. According to CARB's reporting data below, renewable diesel from bio-oils (mostly used cooking oil, tallow, and vegetable oils) are by far the largest and fastest growing source of credits in California's LCFS. [9]

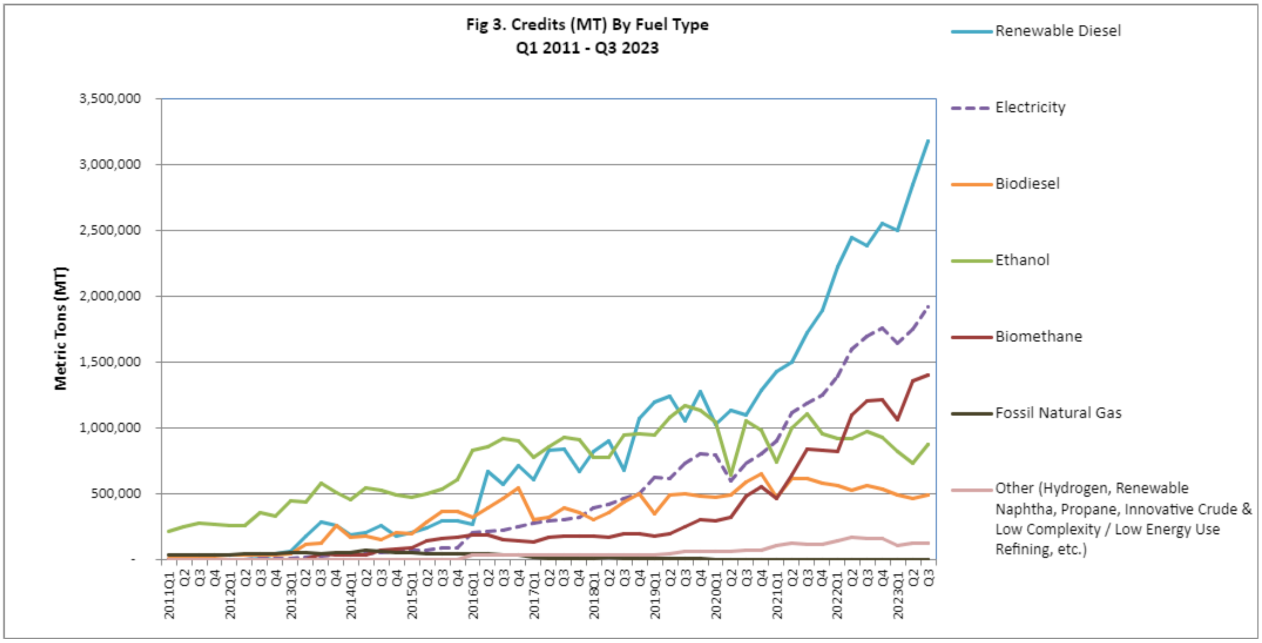
[8] Proposed Amendments to the Low Carbon Fuel Standard Regulation, Appendix A-1, January 2, 2024

[9] Low Carbon Fuel Standard Reporting Tool Quarterly Summaries-Graphs, CARB, October 31, 2023



According to the most recently available data, bio-oil based diesel accounted for 60% of the California diesel fuel market as of the third quarter of 2023.[10] Since CARB has tracked feedstock data, beginning in 2021, quarterly use of crop-oil based fuels has grown by over 350% to 192 million gallons, accounting for 30% of the state's bio-oil diesel market.[11] California's use of crop-oil based fuels is now on track to exceed 700 million gallons in 2023.

In addition, in 2023 CARB certified 29 fuel pathways using soy, canola and corn oil feedstocks, compared with 8 such pathway certifications the year before. This further underscores the potential growth in crop-oil feedstock demand and attendant risks to food markets, climate, and the environment.[12]

While CARB projects that the use of renewable diesel will decline in the future as vehicle standard requirements tighten and the fuel begins generating deficits under the LCFS, CARB's regulatory impact assessment indicates that the *combined* in-state production of renewable diesel and alternative jet fuel alone will increase to more than 700 million gallons by 2028 and more than 800 million gallons by 2040.[13] Beyond in-state production of bio-oil fuel production, a recent study from U.C. Davis projects that strengthening California's LCFS reduction target to 30% by 2030 could result in 100% of the state's 3.5 billion gallons of diesel demand being met by bio-based diesel, most of which derived from vegetable oils.[14] Such a massive influx of vegetable-oil based diesel fuel would not only pose very large indirect land use impacts and potential GHG emissions, but could substantially erode carbon credit prices, which CARB is trying to address.

These recent trends and CARB's projections underscore the urgent need for careful safeguards in the LCFS amendments. Without adequate safeguards, the strengthening of the LCFS carbon intensity

[10] Calculated from Low Carbon Fuel Standard Reporting Tool Quarterly Summaries, CARB, October 31, 2023

[14] Forecasting Credit Supply Demand Balance for the Low-Carbon Fuel Standard Program, Bushnell et al, UC Davis, August 2023.

targets for diesel fuel and diesel substitutes to 74.03 gCO2e/MJ by 2030 and 10.57 gCO2e/MJ by 2045,[15] combined with the newly proposed Automatic Acceleration Mechanism (which increases the stringency of CI targets if triggered[16]) could greatly accelerate the unsustainable growth of crop-oil feedstocks used for making renewable diesel and alternative jet fuel. The resulting and potentially massive increase in demand for crop oil-based fuels markets can contribute to higher food and feed prices, which in turn can accelerate climate-damaging land clearing to accommodate new crop production.

While obligating intrastate jet fuel is an important step in achieving emissions reductions, it will further accelerate demand for crop-oil feedstocks without proper safeguards.

As with strengthening the LCFS targets, our groups have also supported CARB's consideration and intention to obligate fossil aviation fuels as a deficit generating fuel. CARB's proposal to eliminate the exemption for intrastate fossil jet fuel beginning in 2028[17] is an important (if limited) step toward reducing emissions from aviation fuel in California. Intrastate fuels account for approximately 10% of the roughly 3 billion gallons of jet fuel used in California each year.[18] Given the multiple certified fuel pathways for using crop oils as feedstocks for alternative jet fuel, obligating intrastate aviation fuel after 2028 could result in the consumption of several hundred million gallons of additional crop-based aviation fuel in addition to the rapidly increasing market for renewable diesel fuel. In addition, new federal tax credits for sustainable aviation fuels enacted in the Inflation Reduction Act[19] could drive further growth in crop-based alternative jet fuel, which will remain an opt-in fuel for interstate and international flights originating in California.

Rejecting a cap on vegetable oil-derived diesel fuel based on modeled health benefits is unjustified.

CARB's rejection of limits on credits from diesel fuel derived from vegetable oil feedstocks was based on modeled assumptions that particulate matter (PM) and smog-inducing nitrogen oxide (NOx) emissions would decline less than otherwise would occur under the proposed LCFS revisions that allow for continued growth of renewable diesel use. Research prepared for CARB, however, in which fuel blends were tested in diesel engines, concluded that there was no statistical difference in PM or NOx emissions between renewable diesel and fossil diesel used in new diesel engines with modern pollution controls.[20] Due to CARB's 2007 Truck and Bus regulation, all on-road diesels are required to be equipped with modern pollution controls; non-road diesel emission regulations require equivalent emission control regulation on an increasing share of vehicles in that sector as well. Air quality modeling studies by UC Davis have found minimal emission benefits from increasing blends of renewable diesel or biodiesel in 2030 and beyond due to the prevalence of these pollution controls. While biomass-based diesel played a real historical role in reducing emissions from diesel engines, significant evidence indicates that this will not be the case in the future.[21, 22]

[20] Low Emission Diesel (LED) Study Final Report, UC Berkeley for CARB, December 19, 2021.

[21] Modeling expected air quality impacts of Oregon's proposed expanded clean fuels program, UC Davis, March 1, 2023.

[22] Quality Impacts of Renewable Diesel and Sustainable Aviation Fuel (SAF) in California, UC Davis, presentation to the Joint Sustainable Aviation Fuels Subcommittee of the Transportation Research Board, January 8, 2024.

The proposed sustainability requirements for crop- and forest-based biofuels will not limit adverse environmental or food market impacts.

In considering the risks associated with crop-based biofuels, CARB concluded that "biofuel production must not come at the expense of food production or forests".[23] As CARB explained in its draft environmental impact analysis, "cultivation of biofuels on land currently used for food production could result in the conversion of additional existing forest, grassland, or other non-agricultural land to food-related agricultural uses."[24] Guardrails are necessary to avoid increased GHG emissions from land use change. CARB has stated it is considering such guardrails, including volume-based limits, credit limits, feedstock sustainability criteria, explicit bans on particular feedstocks, and bans of feedstocks from particular regions.[25]

The proposed sustainability certification requirement for crop- and forest-based biofuels,[26] however, will not guard against food production or forest impacts. By merely requiring third-party certification that the crop-based feedstocks were derived from land that was not forested as of 2008, without additional criteria to even evaluate secondary market impacts domestically or globally, the updated LCFS will continue to allow bio-oil feedstocks that negatively impact food markets and secondary impacts of expanded conversion of land for crop production, either within the country of the feedstock's origin or other crop-exporting countries. The likelihood of expanded land conversion could hinder the very GHG emissions reductions the LCFS seeks to achieve.

For example, this past December, a pathway application from Phillips 66 for importing soy oil from Argentina was approved by CARB.[27] As Argentina is the second largest exporter of soy meal and oil[28], any substantial diversion of exports from Argentina to California will likely create demand for expanded soy and/or palm oil production with impacts on food markets and/or forests that the proposed sustainability requirement would neither prevent nor track.

Recommendations

Given CARB's intention to strengthen and extend the carbon intensity benchmarks of the LCFS program and to obligate intrastate aviation fuels and considering the unexpected, highly risky, and rapid growth of bio-oil based fuels that will be accelerated by stronger targets and obligating aviation fuels, our organizations strongly recommend the following:

1. **CARB should limit the volume of first-generation vegetable oil-based fuels that are eligible to generate credits under its LCFS program.**

We propose the following mechanisms for limiting such fuels. First, CARB could establish a percentage-based system, based on the volume of diesel and aviation fuels sold in the state, such that only a certain percentage of credits may come from biolipid feedstocks. Alternatively, CARB could cap the total number of credits that may be generated from these fuels. In each of these two scenarios, the carbon intensity of the subsequent volumes of biolipid-based fuels would revert to the base fossil fuel CI score

once the percentage or cap was surpassed. CARB should set these limits and add them to the updated LCFS, either in 17 C.C.R. § 95486, “Generating and Calculating Credits and Deficits” or 17 C.C.R. § 95486.1, “Generating and Calculating Credits and Deficits Using Fuel Pathways.”

2. **CARB should conduct annual assessments of the direct and indirect market impacts from fuels obligated under the proposed Sustainability Requirements.**

CARB should assess and report on an annual basis the market impacts on crop prices, acreage, and exports resulting from diverting bio-based feedstocks to biofuel production and imports that are obligated under the proposed Sustainability Requirements.

3. **CARB should extend the sustainability requirements beyond crop oils to used cooking oil (UCO) and waste oils.**

While UCO and waste oils are preferable and have lower carbon intensities than crop oils, there are existing markets for these oils that will otherwise turn to crop-based oils when UCO and waste oils are used to produced biofuels for use in California, which also results in land-use change impacts. Furthermore, instances of fraud of crop oils, such as palm oil, being passed off as waste oil have been reported and investigated.[29] Given the number of pathways that CARB has approved for imported waste oils, requiring 3rd party certification for these feedstocks and fuels is warranted.

With great appreciation for the tremendous effort CARB staff have invested in developing and proposing important revisions to California’s Low Carbon Fuel Standard, we thank you for your consideration of our recommendations and would be glad to elaborate or discuss these issues further.

RE: Proposed LCFS Amendment Comments

Dear California Air Resources Board,

Imperial Western Products is a biodiesel producer and organics recycling company based in Coachella, California. We would like to provide our perspective on several aspects of the proposed amendments.

Benchmark CI reduction schedule

227.1a Current low LCFS credit values are driven in large part by oversupply due to a rapid acceleration in the amount of imported renewable diesel to CA starting in 2021. This trend does not show any signs of abating. To increase and stabilize credit values in the short and medium term, we support increasing the one-time step down in 2025 from 5 % to 8 %. We would also encourage CARB to explore ways to build more flexibility into
227.1b the AAM as to reduce lag time between the trigger criteria being met and the benchmark CI adjustment being implemented.

Less Intensive Verification

227.2 We echo the remarks of other producers and verification bodies to allow verification bodies to skip site visits to both production and intermediate facilities if they have visited the site in the last two years and issued a positive verification statement. Excessive site visit requirements add significantly to the cost of annual verification services, often require high CI air travel, and provide virtually no information which could not be provided by leveraging technology (photos, video calls, screen sharing).

Respectfully,

Joseph Boyd
Director of Engineering

Re: Proposed Low Carbon Fuel Standard ("LCFS") Amendments, Initial Statement of Reasons ("ISOR")

Rivian Automotive, LLC, ("Rivian") appreciates the opportunity to submit comments on the ISOR for this critical rulemaking. The LCFS is a proven emissions reduction policy and a powerful enabler of transportation electrification. To date, it has served a key role in the state's portfolio of complementary climate policies. We believe it can and must continue to do so if the state wishes to achieve carbon neutrality.

228.1 Consistent with the direction provided through workshops and a Board update in 2023, the ISOR proposes to strengthen the LCFS targets and make valuable changes to the regulation's infrastructure crediting provisions. In general, Rivian supports these proposals—particularly a one-time 'stepdown' in the carbon intensity ("CI") target and implementation of an auto-acceleration mechanism ("AAM"). However, we find that even more stringent CI targets could be appropriate. The ISOR also introduces a novel concept for reforming the Clean Fuel Reward ("CFR"). Rivian has long advocated for a larger role for automakers in earning and investing a share of residential charging base credit revenue. CARB should still consider the benefits of such an approach even if it decides to move forward with the new CFR concept in parallel. That proposal is potentially promising, but the implementation details will matter a great deal. To maximize the impact of a new CFR for medium- and heavy-duty ("MHD") vehicles, medium-duty zero-emission vehicle ("ZEV") pickups must be eligible and the CFR's governance structure reformed to include MHD ZEV manufacturers.

Keep the World Adventurous Forever

Founded in 2009, Rivian is an independent U.S. company headquartered in California. With over 16,000 employees across the globe, Rivian's mission is to Keep the World Adventurous Forever. Rivian's focus is the design, development, manufacture, and distribution of all-electric adventure vehicles, specifically pickups, sport utility vehicles ("SUVs"), and commercial vans. Key to the success of our mission, these vehicles will displace some of the most polluting conventional vehicles on the road today.

Rivian brought the first modern electric pickup to market in 2021 when we launched the R1T from our manufacturing facility in Normal, Illinois, followed shortly thereafter by the R1S SUV and the EDV commercial van for Amazon. The R1T and R1S—both medium-duty passenger vehicles ("MDPVs")—provide all-electric options in segments where added utility is a necessity. The R1T has an EPA-certified range of up to 410 miles. The R1S is certified at up to 400 miles. The truck also features 11,000lbs of towing capacity, while the R1S is a seven-passenger full-sized SUV. Both are well-equipped for off-roading in a range of climates. Separately, our Class 2b and 3 commercial vans eliminate tailpipe emissions from last-mile delivery. Rivian is committed to producing 100,000 vans for our launch customer, Amazon, with more than 10,000 already in service in more than 800 U.S. cities. The van is now also available for purchase by other fleet customers in addition to Amazon. Beyond our vehicle lineup, Rivian is also building a network of public DC fast chargers across the country known as the Rivian Adventure Network ("RAN"). More than 14 RAN sites with 84 dispensers are already up and running in California alone.

Rivian Welcomes the 2024 Rulemaking to Amend and Extend the LCFS

The LCFS is a keystone regulation in California's portfolio of climate policies. As the 2022 Scoping Plan stated, the LCFS "is the primary mechanism for transforming California's transportation fuel pool" in service of the state's climate goals.[1] Indeed, as an electric vehicle manufacturer and charging provider, the LCFS is a priority for Rivian precisely because of the role it plays in speeding the transition toward renewable fuels in the transportation and electricity sector.

The transition toward renewable fuels is happening faster than the LCFS is currently designed for. Overcompliance with the policy's CI targets has resulted in an overabundance of compliance credits in the market, pushing down prices. Low credit prices jeopardize the very market investments the LCFS relies on to achieve its goals. Amending and extending the policy to keep pace is crucial.

Rivian strongly supports a rulemaking this calendar year and key elements of the staff's proposal, including the:

- **One-time stepdown.** Throughout the workshop process, Rivian called for a one-time stepdown in CI targets and we applaud the inclusion of just such a provision in the ISOR. We recommended an evaluation of several alternatives, including the 18.75 percent reduction in 2025 ultimately
228.1 proposed in the ISOR. We anticipate the proposed adjustment will force a draw on the credit bank that could help rebalance the program. **CARB should finalize a one-time stepdown no later than 2025 and at least as stringent as the one proposed.** (The proposed adjustment to the 2010 baseline CI for ultra-low sulfur diesel would blunt the effect of the stepdown on diesel and might justify a more substantial one-time adjustment.)[2]
- **AAM.** As we and many other stakeholders have noted previously, overcompliance in the LCFS strongly suggests the need for an AAM. In 2022, for example, regulated entities exceeded California's CI target by more than 2.6 percentage points.[3] We anticipate a similar level of
228.2 overcompliance in 2023. Even with a stepdown and more stringent targets in place, in short order the LCFS could very well find itself right back where it is today, with the market consistently and significantly outpacing the policy's CI targets resulting in a credit glut. Absent an automatic ratchet, a policy response would be years away due to regulatory development timelines. Therefore, the staff proposal for an AAM is encouraging. **CARB should approve an AAM as part of the LCFS amendments.**

---

[1] CARB, *2022 Scoping Plan for Achieving Carbon Neutrality*, 190.
[2] CARB, *Appendix A-1: Proposed Regulation Order, Proposed Amendments to the Low Carbon Fuel Standard Regulation*, Table 2, Footnote (a).
[3] CARB, *LCFS Data Dashboard*, available at www.arb.ca.gov/resources/documents/lcfs-data-dashboard.

Nonetheless, we believe the proposal would benefit from a reconsideration of more stringent CI targets. We offer comments on this and several other aspects of the ISOR below.

Consider Greater Stringency

228.3 CARB should bring the LCFS up to date, reflecting conditions in the transportation sector and clean fuels industries that have changed substantially since even 2018 when the Board promulgated the last round of regulatory amendments. This includes exponential growth in the sale of electric vehicles. Increasing the ambition of the regulation's CI targets should be a central pillar of the updates made in the current rulemaking.

Rivian views the staff's proposal for a 30 percent reduction in CI by 2030 as a big step in the right direction. However, we find that **a 30 percent target in 2030 is the minimum level of stringency the Board should consider. The Board should take a closer look at targets greater than 30 percent.**

We recognize that CARB must balance many concerns in this rulemaking, but a reconsideration of the costs and benefits of a more stringent schedule of CI reductions is warranted for several reasons.

1. **Evidence from the credit market suggests deeper CI reductions are possible.** Following the ISOR's publication, type 1 credit prices have fallen over 15 percent. According to CARB data, weekly average credit prices dropped week-over-week throughout the month following the ISOR's release. While not conclusive, this is strongly suggestive of a market conviction that the currently proposed targets can be comfortably achieved.

Chart 1. *Average weekly credit prices fell following the ISOR's publication.*[4]

228.9 2. **The ISOR's analysis shows that the more stringent Alternative 2 would deliver cost-effective additional emissions and public health benefits.** Relative to the baseline, Alternative 2 reduces more greenhouse gas ("GHG") emissions on an accelerated timeline and abates more NOx and PM2.5. In turn, the air quality improvements lead to a variety of public health benefits 11 percent more valuable, in dollar terms, than those delivered under the baseline proposal. Crucially, while

[4] Neste, *California Low Carbon Fuel Standard Credit Price*, available at www.neste.com/investors/market-data/lcfs-fuel-standard-credit-price.

regulated entities incur greater costs under Alternative 2, its GHG abatement cost—$58/ton—compares favorably with the baseline proposal's $57/ton.[5]

Staff cite higher credit prices under Alternative 2 as a reason to reject it. Rivian acknowledges that higher credit prices necessarily raise compliance costs and could introduce greater pass-through costs to some extent for day-to-day consumers of fossil fuels. However, the ISOR itself estimates that the alternative delivers a valuable and cost-effective trade-off in terms of environmental and public health benefits. The LCFS is fundamentally an emissions reduction policy aimed at addressing climate change and air pollution. Cognizant of the rapidly worsening consequences of climate change and a persistent air quality crisis in the state, we believe CARB should take seriously the alternative that cost-effectively accelerates GHG reductions and maximizes air quality improvements in the shortest possible time.

Moreover, CARB should consider how the higher credit prices modeled under Alternative 2 would play in the full arc of the LCFS regulation and against the backdrop of California's broader goals. By 2045, the ISOR proposes a CI reduction target of 90 percent, supporting the 2022 Scoping Plan objective of carbon neutrality and an 85 percent reduction in GHG emissions by the same year. Higher credit prices in the near term will call further investment in to the market today to support compliance with much more ambitious CI targets in the outyears. We believe this is a compelling reason to consider additional stringency in the pre-2030 timeframe.

3. **It is unclear whether the modeling baseline accurately accounts for EV market growth.** In Rivian's
228.10 analysis of the ISOR and supporting documentation, we found it challenging to identify and validate with certainty the assumptions regarding future EV volumes—and therefore future consumption of electricity as a transportation fuel—that underpin the agency's modeling. Underestimating future EV volumes would result in a conservative policy recommendation.

Rivian consulted the ISOR, the Standardized Regulatory Impact Assessment ("SRIA"), and the California Transportation Supply ("CATS") Model technical documentation cited by the SRIA.[6] We did not find a downloadable data file plainly documenting the EV stock and electricity consumption estimates underpinning the modeling conducted to support the ISOR. We respectfully request that CARB furnish this information, providing stakeholders with an unambiguous understanding of the EV population and energy demand figures relied upon by the staff.

What the SRIA and CATS documentation do provide, however, are narrative descriptions of the key assumptions. Specifically, we understand that annual light-duty EV stocks follow the Scoping Plan's

---

[5] CARB, *Staff Report: Initial Statement of Reasons* (December 19, 2023), available at www.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf.

[6] CARB, *Appendix C-1: Standardized Regulatory Impact Assessment (SRIA), Proposed Amendments to the Low Carbon Fuel Standard Regulation* (September 9, 2023), available at www.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appc-1.pdf; CARB, *California Transportation Supply Model—Technical Documentation v0.2* (March 2023), available at www.arb.ca.gov/sites/default/files/2023-03/CATS%20Technical%20v0.2.pdf.

Proposed Scenario while heavy-duty EV stock numbers reflect those in EMFAC2021 v.1.02.[7] However, this raises at least two issues for clarification by staff.

- EV stock estimates in the Scoping Plan's Proposed Scenario do not reflect those found in other sources, including the dashboard maintained by the California Energy Commission ("CEC"). According to the CEC, EVs numbered approximately 1.1 million in California at the end of 2022, the last year for which CEC data are available.[8] Yet the Scoping Plan's Proposed Scenario estimates just 738,428 EVs on the road that year.[9] Similar discrepancies exist between the CEC and the Scoping Plan's Proposed Scenario for EV sales. To the extent that the Scoping Plan's assumptions consistently understate or are behind the curve of the true pace of vehicle electrification in the California market, it will affect the modeling of CI reduction targets.
- To the best of our knowledge, EMFAC2021 does not incorporate expected compliance with the Advanced Clean Fleets ("ACF") rule.[10] CARB promulgated ACF after finalization of EMFAC2021. Yet the SRIA states clearly that ACF is "represented in the baseline."[11] The CATS documentation states that heavy-duty stock numbers, specifically, flow from EMFAC2021 but that the BEV-FCEV split mirrors the adjustment factors used in the ACF's development.[12] Ultimately, we find the combined descriptions opaque and remain unsure of the MHD EV stock assumptions used in the ISOR. If staff modified EMFAC2021 or took other steps to account for ACF, the ISOR and supporting documentation should explicitly say so.

To clarify these issues, Rivian recommends that CARB publish its EV stock assumptions in a clear and digestible format for stakeholder review. At a minimum, publishing a clear database of model inputs aids transparency and would avoid confusion. An accurate, verifiable, and up-to-date picture of the on-road EV population in California is vital for developing an LCFS regulation that maximizes its potential.

Expand and Extend Fast-Charging Infrastructure ("FCI") Pathway Credits

228.4 Rivian welcomes the qualified extension of light-duty ("LD") FCI crediting in low-income, rural, or disadvantaged communities as well as the expansion of the FCI pathway to include medium- and heavy-duty ("MHD") FCI at both public and private sites.

Public LD FCI projects merit continued regulatory support through the FCI pathway. Building public confidence in the availability of charging infrastructure remains a top priority, especially in low-income, rural, or disadvantaged communities. Rivian's RAN product is intended to support EV adventure and exploration in every corner of the country. Coupled with our highly capable pickup and SUV offerings, serving rural communities with relatively lower utilization is aligned with the company's mission and the purpose of our vehicles and charging product. We look forward to leveraging the FCI pathway to expand the footprint of RAN into high-need regions across California. We appreciate that the proposed regulation defines rural, low-income, and disadvantaged locations in an easily understood and implementable manner consistent with existing definitions found elsewhere in California law. This is crucial for smooth implementation by charging providers.

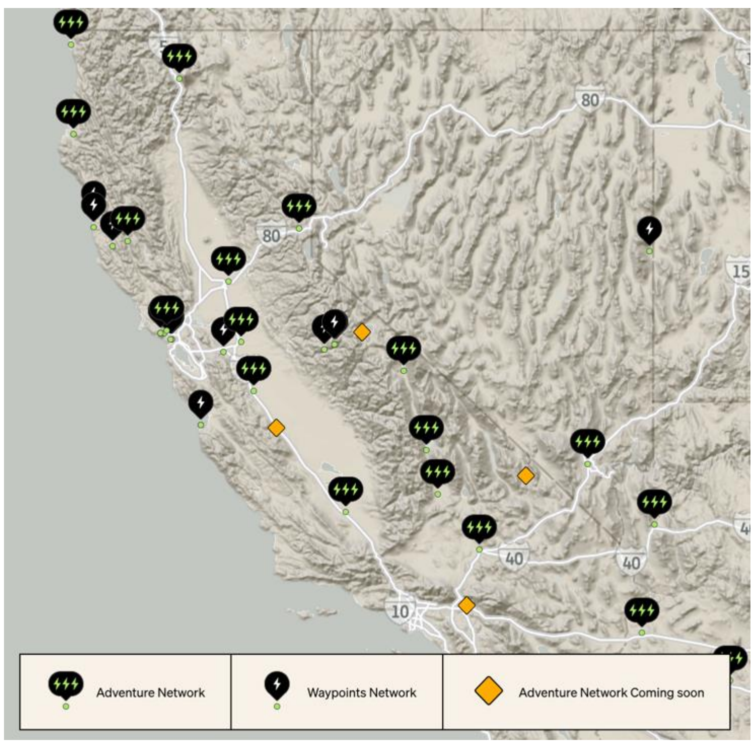

Figure 1. *Rivian's charging network is growing across California.*

We urge CARB to reconsider the cap on credits in this pathway, currently proposed at 0.5 percent of deficits from the prior quarter. Deploying public chargers remains as important today as it is financially challenging—all the truer in high-need regions of the state. As the lack of charging infrastructure is often cited as the number 1 concern for prospective EV owners, this is not the time to cut back on regulatory support for vital infrastructure.[13] **Rivian strongly recommends preserving the existing limit of 2.5 percent of deficits from the prior quarter.**

The expansion of the FCI pathway to MHD infrastructure is a welcome development that Rivian supported conceptually throughout the workshop process. Capacity-based crediting will bolster the business case for early deployment of MHD FCI investments, which in turn will build confidence in the viability of MHD EV products and drive their sale and use. Additionally, allowing private-facing fleet chargers to qualify is a crucial addition to the pathway, coming at a moment of accelerating efforts to electrify MHD fleets in compliance with ACF mandates. As the staff rightly acknowledge, installing private FCI for MHD EVs can be a challenging financial proposition and the possibility of earning credits via the MHD FCI pathway could complete the capital stack for important projects across the state.

Establish a Pragmatic Approach to Third-Party Verification

The ISOR proposes to introduce third-party verification requirement for an expanded list of electricity credit pathways. This includes a proposed requirement that verifiers "annually visit each facility; and, if
228.5 different from the fuel production facility, the central records location for which the records supporting an
application or report subject to verification are submitted."[14] Notably, the proposed regulations only exempt unmetered residential EV charging implying that third-party verifiers must conduct site visits for metered residential charging.

We urge CARB to reconsider the proposals and establish pragmatic requirements that account for real-world implementation concerns. In this regard, we align ourselves with the recommendations of other stakeholders including 3Degrees and Bridge to Renewables.

- **Reduce the site visit burden for non-residential charging.** In the case of designated reporting entities or entities exceeding a reasonable registered FSE count threshold, require that verifiers need only visit the designated reporting entity's central location for recordkeeping and a reasonable sample of facilities. California is home to thousands of pieces of FSE. It is simply not feasible nor cost-effective to require regular visits to each. CARB could also consider alternative approaches, such as attestations for registered FSE like those required under Oregon's regulation.
- **Exempt metered residential charging from site visit requirements.** Site visits to residential locations would be impractical, raise privacy concerns, and incur costs—estimated by the staff at $6/MWh—that would significantly erode the economics of the incremental credit pathway. The implications of potentially disincentivizing automaker generation of incremental credits include relatively more carbon-intense EV charging, diminished market pressure to accelerate the development of renewable electricity generation, and the potential loss of the best available data on residential EV charging, which CARB now uses to establish base credit volumes. We also note a fairness concern in that non-metered charging, used to generate far more lucrative base credits for utilities, are not subject to verification requirements. CARB should direct staff to revise the final

[13] Rob Schmitz and Camila Domonoske, *NPR*, "Major Sticking Point to Buying an Electric Vehicle is the Lack of Public Chargers," July 6, 2023, available at www.npr.org/2023/07/06/1186154285/major-sticking-point-to-buying-an-electric-vehicle-is-the-lack-of-public-charger.

[14] 17 CCR §95501(b)(3)). Rivian acknowledges that the proposed regulation order includes a provision for "less intensive verifications" in certain circumstances. But even if utilized this does not eliminate the costly and infeasible burden of a site visit to each facility at least once every three years.

regulatory language in §95500(c)(1)(E)(1) to state, "EV Charging except as specified under 95491(d)(3)(A) *and 95491(d)(3)(B)*" (new text in italics). This would exempt both metered and non-metered residential charging from third-party verification.

Align Low-CI Electricity Requirements with Other Clean Fuels Programs

228.6 CARB should make renewable energy certificates ("RECs") supplied by generation assets in the entire Western Electricity Coordinating Council (WECC) footprint, and not just directly transmitted into the state, eligible to meet the requirements for low-CI electricity pathways. Broadening REC generation eligibility would incentivize the buildout of renewables where they can have a greater avoided emissions impact and harmonize with the rules governing similar pathways in the Oregon and Washington clean fuels regulations. Increasing the REC supply would also protect against the potentially unintended upward cost pressure we have already seen from limiting eligibility to only resources in-state or directly transmitted into the state. Inflated REC prices, coupled with a depressed LCFS credit price, could undermine participation in the low-CI electricity pathway. We believe a reconsideration of REC eligibility would strike a balance between supporting the development of impactful projects while protecting against the unintended consequences under the existing rules.

Maximize the Impact of Residential Charging Base Credits

228.7 In previous comments, workshop input, and engagement with CARB, Rivian advocated consistently for a fresh approach to the use of revenue earned from residential EV charging base credits. We welcome staff and Board consideration of alternative structures and uses for base credit revenue.

Rivian previously recommended regulatory amendments that allow for EV manufacturers to share in base credit generation. Clean fuels policies are intended to be market-based systems that create incentive structures for private sector investments by the providers and users of clean transportation fuels. In the light-duty vehicle sector, the two most important market participants are vehicle manufacturers and their customers. Consistent with the core principles of the LCFS, the policy should encourage the participation of these market actors and reward them for making investments in EVs.

Rivian's preferred approach would incentivize automakers to empirically substantiate its vehicles' residential charging activity with telematics data by allowing manufacturers to earn base credits in return. **With a sufficiently large allocation of base credits, manufacturers whose vehicles generate credits (light-duty and medium-duty) could operate the Clean Fuel Reward ("CFR") more efficiently and sustainably than under the utility-led framework.**[15] We were disappointed that the ISOR did not consider such a concept. With CARB's decision to sunset the Clean Vehicle Rebate Project, the CFR would be the last universally available EV purchase incentive in the state—a key tool for sustaining the EV market's growth into the mainstream of the consumer market.

The staff has instead proposed a significant revision to the allocation of base credits. The majority are now proposed to go to the 'holdback' pool, with the remaining credits supporting a reformulated CFR for MHD EVs (more on this below). If CARB finalizes this overall funding structure, **Rivian recommends that the**

[15] Rivian has previously submitted comments along these lines both individually and in partnership with shared-vision partners. See for example comments submitted by Rivian and in coalition with Audi, Tesla, and Bridge to Renewables.

Board award a durable and significant share of holdback credits to automakers on the condition that the
228.7a revenues fund investments to advance transportation electrification and lower the total cost of EV ownership. These investments could include all or some of the following, with an appropriate carveout for administrative costs:

- Annual dividend checks returned to customers, paying out the value of charging credits.
- Rebates on home EVSE purchases.
- Public charging infrastructure deployment.
- Vehicle-grid integration ("VGI") technology development and implementation.[16]

CARB could establish a 'menu' of investment options for automakers including several of the above categories, or others, to provide flexibility for participants. The regulation could prescribe additional detail. Automakers would report to the Board annually on their expenditures.

228.7b **In parallel, allocating remaining base credits to funding a CFR for qualified MHD EVs is potentially promising.** As a general proposition, Rivian strongly supports targeting additional incentive dollars at fleet buyers of MHD EVs. If the proposal to establish an MHD CFR can create a reliable and sustainable purchase incentive in place of the existing light-duty CFR, with its many challenges, it will be a welcome achievement.[17]

In recent years, CARB has rightly focused on abating emissions from the MHD sector, developing cutting-edge regulations including the Advanced Clean Trucks ("ACT") and ACF rules that will help push the pace of electrification in the MHD fleet. Rivian strongly supported both ACT and ACF. However, ACF's exemption for small fleets, coupled with their resource constraints and reduced appetite for risk, mean that regulators need to consider additional policy measures to spur the purchase of MHD EVs by those operators. Redirecting the CFR to incentivize small fleet purchases of MHD EVs is a potentially impactful change—albeit one that departs from the LCFS' first principles by using LCFS credit revenue earned by one set of market participants to incentivize behavior by another.

An additional benefit of an MHD CFR is that it could steer some LCFS benefits to take-home fleets. The regulation's current structure and flow of credits makes it impossible for owners of take-home fleet vehicles, such as medium-duty pickups and vans, to receive incentives under the policy. This is a major 'blind spot' of the LCFS and one that Rivian has highlighted in previous comments and engagement with CARB. Rivian continues to believe that allocating base credits to vehicle manufacturers would create the conditions for a more direct and efficient solution to this problem. However, to the extent that take-home fleet vehicles are disproportionately represented among the small fleets targeted by the MHD CFR, this proposal would use LCFS credit proceeds to benefit a population of vehicle owners and users that otherwise fall through the gaps of the policy.

---

[16] VGI enables customers to fully extract the value of their vehicle as a load management tool and grid asset and help reduce costs for all ratepayers.

[17] The existing light-duty CFR proved volatile and unreliable, with administrators cutting the rebate's value and ultimately suspending the program entirely. Even if it were still active, the rebate as currently formulated excludes a growing lineup of EVs technically classified as medium-duty passenger vehicles that create significant credit value under the LCFS but exceed the light-duty vehicle definition used to define rebate-eligible vehicles.

If the Board elects to finalize the MHD CFR, Rivian stands ready to support implementation, beginning with careful consideration of the following key issues and concerns.

228.7c
- **Clearly make medium-duty ("MD") EV pickups eligible for the CFR.** MD pickups comprise approximately 60 percent of the MD truck and van market and those in turn account for the majority of all MHD vehicle sales.[18] Moreover, MD pickups are the workhorse of many fleets. A variety of EV pickup models now exist in the marketplace and can serve fleet needs. However, the state's main MHD EV incentive program, HVIP, categorically excludes pickups from incentive support. To achieve the state's targets for MHD electrification, EV pickups must receive the same policy support as other categories of MHD vehicles. CARB should direct that the full range of MHD EVs, including pickups when purchased by ACF-exempt fleets for fleet use, be eligible for the reformed CFR.

228.7d
- **Tier rebates by vehicle class.** CARB should direct that the CFR provide rebates tiered by vehicle class—making the most of the available resources and reflecting the often-substantial difference in the purchase price of MHD vehicles.

228.7e
- **Allow fleets to combine the CFR with other incentives, including HVIP vouchers.** To maximize the benefits and simplicity of the reformed CFR, it should be offered on the hood and by right to qualified fleet purchasers and made 'stackable' with other incentives, including HVIP vouchers. 'Stack-ability' is not just a matter of maximizing incentives for fleets, though that is a worthy objective in and of itself. It also provides certainty for fleets when budgeting for vehicle procurements, while streamlining program implementation for administrators who would not need to verify whether applicants have already applied for or received other incentives.

228.7f
- **Invite MHD ZEV manufacturers to participate in the governance of the CFR in partnership with the utilities.** As Rivian understands the proposal, the new CFR would be administered by the utilities much like the existing light-duty CFR. Light-duty manufacturers have historically been included in the CFR's governance structure in an advisory capacity. We recommend that the new CFR be guided by a collaboration between the utilities and MHD manufacturers. CARB should direct that a steering committee be formed comprising utilities and all major MHD ZEV manufacturers to collaborate on the details of the program's design and implementation.

The Board should clearly signal its intent that the CFR operate in accordance with the above recommendations.

Conclusion

Rivian welcomes the current rulemaking to revise and extend the LCFS. The LCFS is a powerful policy that, with the right reforms, can contribute even more to the state's efforts to address climate change and electrify transportation. Moreover, urgent action is needed to match the policy's CI reduction requirements with the real-world performance of the clean fuels market. Rivian recommends that CARB consider even greater stringency than proposed, implement an AAM, and finalize the FCI pathway amendments without a lower cap on credits in the LD FCI pathway. In addition, CARB should take a more pragmatic approach to third-party verification requirements for electricity crediting in both non-residential

[18] U.S. Environmental Protection Agency, *Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis* (April 2023), 3-10.

and metered residential contexts. Finally, Rivian reiterates the benefits of awarding automakers a share of residential base credits, whether in sufficient quantity to restore the existing CFR or to fund other investments in transportation electrification. If CARB decides to move forward with the reformed CFR for MHD EVs, we respectfully urge that MD pickups be eligible and MHD manufacturers be included in the program's advisory committee. As a manufacturer of MHD EVs, Rivian stands ready to support the design and implementation of an MHD CFR.

Rivian values this opportunity to provide feedback and is excited about the prospect of strengthening the LCFS. Thank you to the staff for all the hard work that goes into a rulemaking of this magnitude.

Please contact me with any questions about our comments. Rivian looks forward to the upcoming workshop and future Board hearing.

Sincerely,

Tom Van Heeke

Re: California Association of Sanitation Agencies Comments on the Low Carbon Fuel Standard Proposed Regulatory Revisions

Dear Mr. Botill and Ms. Laskowski:

The California Association of Sanitation Agencies (CASA) appreciates this opportunity to provide comments on the proposed revisions to the Low Carbon Fuel Standard (LCFS) as published January 5, 2024. For the reasons articulated below, CASA urges CARB to carve out the wastewater sector to
229.1 preserve use of our non-fossil renewable wastewater-derived biomethane (biogas) in the LCFS program indefinitely. We will continue to produce and capture the biogas, as well as strive to beneficially use (not waste) it for as long as we are performing the essential public service of wastewater and solids treatment with anaerobic digesters. We have made similar arguments during the Scoping Plan Update and the more recent development of the Advanced Clean Fleet (ACF) regulations. The CARB Board included language in the last paragraph of the adopted Resolution 23-13 (included at the end of this letter) accompanying the adoption of the ACF Regulations directing staff to work with sister regulatory agencies and CASA to ensure multiple long-term uses of our biogas.

CASA is an association of local California wastewater agencies, known as Water Resource Recovery Facilities (WRRFs), engaged in advancing the recycling of wastewater into usable water, as well as the generation and beneficial use of renewable energy, biosolids, fuel, and other valuable resources. Through these efforts we help create a clean and sustainable environment for Californians. Our members are focused on helping the State achieve its climate change mitigation mandates and goals, which include:

- Reducing short-lived climate pollutant (SLCP) emissions by accepting and co-digesting diverted organic (food) waste from landfills pursuant to SB 1383
- Reducing carbon intensity of transportation fuel by using the biogas we generate
- Providing 100 percent of the state's energy needs from clean and renewable sources
- Increasing soil carbon and carbon sequestration by land applying biosolids and supporting the Healthy Soils Initiative, Climate Smart Strategy, and Wildfire and Forest Resilience Action Plan

As we have noted in previous discussions and comment letters for both the ACF and LCFS regulations, the wastewater sector represents an important in-state partner for development of low-carbon fuels as well as for meeting SB 1383 organic waste diversion requirements. As documented in the report released in August 2020 assessing co-digestion capacity at WRRFs, the California State Water Resources Control Board (SWRCB) estimated total existing available wastewater digester capacity may be able to receive all food waste required to be diverted from landfills in California for co-digestion. This will exponentially increase the biogas produced and captured at WRRFs.

The wastewater sector is aligned with LCFS program goals, notably to diversify transportation fuels away from fossil fuel-based sources and achieve carbon neutrality. As noted by the SWRCB, WRRFs across California have the ability to increase co-digestion in support of SB 1383 implementation but can only do so if it is cost-effective. The economic analysis performed as part of the SB 1383 process identified use of the biogas (resulting from digesting the diverted organic waste) as a low carbon transportation fuel supporting the program's feasibility.

The LCFS program should continue to provide a viable incentive for co-digestion of diverted organic waste and the conversion of WRRF renewable biogas to biomethane transportation fuel. In addition to the ACF Regulations, we are concerned CARB's proposal to phase out the use of WRRF biomethane in the LCFS program by 2040 will further inhibit SB 1383 implementation. Implementation of SB 1383 is in its very early stages – however, 75% diversion of organics away from landfills is required by January 1, 2025. With implementation at WRRFs, co-digestion will increase significantly to meet the mandate, in turn, so will diversified uses of WRRF biogas. However, CARB is proposing to phase out the avoided landfill methane credit, which disincentivizes the production and use of non-fossil renewable organic waste-derived biomethane in the LCFS program. At the same time, CalRecycle incentivizes co-digestion in their regulations to implement SB 1383 by requiring jurisdictions that must divert organic waste to procure a corollary product of that diversion, including the use of biogas as a low carbon transportation fuel. While the LCFS program has not been widely utilized at WRRFs to date, we expect that to shift as co-digestion becomes more common. The success of SB 1383 hinges on the public wastewater sector accepting diverted food waste for co-digestion but that will only occur if it is cost-effective and we are assured of the ability to beneficially use all our biogas.

229.1 cont

We strongly urge CARB to preserve the use of our biogas as a viable low carbon fuel in perpetuity since it will always be produced and SB 1383 implementation hinges on its beneficial use. Similarly, the proposed ACF Regulations will also inhibit SB 1383 implementation by limiting the use of medium- and heavy-duty trucks using WRRF biogas-derived compressed natural gas to only those in our fleets as of January 1, 2024 – we have proposed that be extended to follow the implementation of SB 1383 and provide WRRFs a pathway for use of the increased biogas. As CASA noted in our comments on the proposed ACF Regulations (and CARB staff acknowledged this in their December 12, 2022 presentation), medium- and heavy-duty electric trucks and vehicles unique to the needs of our sector are not commercially available and we do not expect them to be for many years. Likewise, biogas-to-hydrogen as a transportation fuel for these vehicles is not yet commercially available or demonstrated, both research and demonstrations are necessary to advance that technology and we have offered to work with CARB on those efforts. In the meantime, state regulations and policy should promote biogas deployment using proven technology that most efficiently reduces GHGs to mitigate climate change while also complying with the Omnibus regulations.

CASA has previously had productive discussions with CARB where it seemed understood that multiple benefits are realized through co-digestion and that credit should be awarded for the GHG emission reductions achieved. This requires immediate further action by either developing new simplified calculators or integrating existing ones for sewage sludge digestion and diverted food waste digestion as a Tier 1 option. Rather than phasing out the use of WRRF-derived biogas from the program, prioritizing a diverted food waste pathway within a co-digestion system at WRRFs would encourage SB 1383 organic waste diversion as well as accelerate development of low-carbon fuel production from these systems. Certification of a fuel pathway for each individual co-digestion feedstock would be onerous and we suggest that the food waste contribution to biogas production be prioritized and prorated. We strongly recommend a simplified approach assuming a baseline biogas production from sewage sludge digestion operating within defined parameters (mean cell residence time, temperature, volatile solids destruction, etc.) and assume all additional biogas is the result of the additional organic waste feedstock, eliminating the unnecessary burden of excessive testing. A similar approach has been adopted by the USEPA as part of their Renewable Fuel Standard regulatory revisions in June 2023.

In order for the receipt of diverted food waste for co-digestion to be viable, it must be cleaned of contaminants so as not to have adverse impacts on equipment, the microbial community in the anaerobic system, nor on the biosolids which are another product of digestion. LCFS credits, particularly those with a negative carbon intensity (CI) value, could be a strong economic incentive to invest in the needed equipment and the ability to accept more food waste. To achieve the state's organic waste diversion and GHG emission reduction goals, it is critical that the appropriate pathways are established in an expeditious manner to provide this incentive. We strongly urge CARB staff to work with CASA and our members to extend and expand these pathways that can serve as a model for others.

Specific comments are as follow:

229.2

1. We support the increased reductions in carbon intensity as proposed. This includes a 25% reduction by 2025; a 30% reduction by 2030; and a 90% reduction by 2040.

229.1 cont

2. Section 95482(g): we disagree with the proposed phase out of the use of biomethane as a transportation fuel as articulated above.
3. Section 95488.9(f)(3): we disagree with the proposed phase out of avoided methane crediting for both biomethane and hydrogen from biomethane sources. The rationale is provided above.

We appreciate this opportunity to comment and your willingness to consider our recommendations. We look forward to continued collaboration to develop pragmatic solutions to these issues. Please let me know if we can set a time to meet for discussion of our recommendations. I can be contacted at gkester@casaweb.org or at 916-844-5262.

Sincerely,

Greg Kester

Cara Morgan, CalRecycle

Last Paragraph of Resolution 23-13:
Be it further resolved that, consistent with the latest Scoping Plan, the Board recognizes that the successful implementation of the food waste diversion requirements and methane emissions reductions mandated by SB 1383 are critical to the State's climate goals. The Board further recognizes that multiple reliable uses for non-fossil biomethane will be needed for successful implementation. The Board recognizes the need for coordination meetings with other state agencies such as CEC, CPUC, State Water Resources Control Board, CalRecycle, CDFA, CNRA, California Division of Occupational Safety and Health, and other relevant stakeholders such as the California Association of Sanitation Agencies and the California Air Pollution Control Officers Association, to implement SB 1383 and SB 1440. As such, the Board directs staff to prioritize policy discussions related to SB 1383 and SB 1440 implementation and discussions on how to transition biomethane into hard to decarbonize sectors, or as a feedstock to produce hydrogen for FCEV fuel and to produce electricity to charge BEVs to achieve the SB 1383 target. The Board further directs staff to report to the Board by the end of 2025 on progress for alternative uses of biomethane, including identifying any appropriate regulatory actions as needed.

LEADERSHIP COUNSEL FOR JUSTICE & ACCOUNTABILITY

February 15, 2024

Dear Governor Newsom and Members of the California Air Resources Board:

We write to express our collective concerns regarding the Air Resources Board's (CARB) proposed rulemaking that doubles down on polluting factory farm biogas as the most lavishly incentivized transportation fuel under the state's Low Carbon Fuel Standard (LCFS). Factory farm biogas is not clean energy, and CARB staff's embrace of this false solution for the next two decades throws Californians already subjected to some of the worst environmental pollution in the nation under the bus. The proposed amendments to the LCFS fly in the face of years of advocacy by environmental justice and climate advocates and blatantly ignore California's commitment to a just climate transition.

We call for immediate and meaningful action to fix the environmental injustices and abuses that have become inherent in the program and that the proposed amendments lock in place for over 20 more years.

California's LCFS, originally conceived as a tool to combat climate pollution in the transportation sector, has been exploited and manipulated by powerful corporations, particularly Big Ag and Big Oil. Rather than serving its intended purpose, the LCFS has become the nation's largest and most lucrative pollution trading scheme for factory farm biogas across the country.

In its current form, the LCFS rewards and entrenches some of the worst factory farming practices, both in California and across the country, providing lavish subsidies to operations that are getting paid to pollute. The program's flawed accounting practices assign factory farm biogas a lower "carbon intensity" than even solar and wind energy, creating a smokescreen for the continued pollution of the fossil fuel industry.

Polluters such as Chevron can offset their emissions by paying industrial factory farms to extract methane gas from on-farm waste. This so-called "biogas" is then traded in California's credit system, providing a misleading cover for continued pollution from fossil fuel operations.

Factory farm biogas' extremely negative carbon intensity scores are based on several fundamental flaws. First, CARB is ignoring greenhouse gas emissions from the underlying factory farming operations as well as the increased greenhouse gas emissions when operators use and dispose of the digester waste. Second, CARB refuses to acknowledge that methane emissions from livestock manure cesspools is a choice and can be avoided with more sustainable practices like dry manure handling. For years, the LCFS operated under a rational framework that did not assume perpetual free-venting of methane pollution from livestock operations. CARB staff made the change to today's perverse "avoided methane crediting" policy in 2019, kicking off a nationwide expansion of factory farm biogas operations—a concerning trend dubbed the "manure gold rush."

The existing LCFS rules perpetuate environmental injustice by disproportionately harming low-income communities and communities of color. Factory farms, predominantly located in these marginalized areas, cause severe harm to air, water, public health, rural economies, and overall quality of life. The extraction of methane from factory farm cesspools does nothing to alleviate the massive harm inflicted by mega-dairies and large factory farms on these communities.

This rulemaking package put forward by CARB staff claims to “Uplift Environmental Justice,” but entirely ignores the central environmental injustice that has been the focus of advocates' calls for LCFS reforms for over two years. Staff’s willful ignorance of how the LCFS is harming Californians is egregious and is the latest example of a rogue agency unwilling to hear the voices and lived experiences of those living near large dairies in the state.

This disregard is all the more stunning considering the Environmental Justice Advisory Committee's (EJAC) raised concerns with factory farm biogas in its resolution to reform the LCFS in this rulemaking to address the injustices embedded in the current program.

Governor Newsom's California Air Resources Board (CARB) has a pivotal opportunity this year to adopt a new rule that aligns the LCFS with California's environmental justice commitments. The Environmental Justice Advisory Committee has presented a clear and effective alternative to the current policies that reward polluters.

We demand the following reforms to the LCFS aimed at stopping incentives for factory farms and factory farm gas:

230.1 1. Eliminate "avoided methane crediting" in 2024.

230.2 2. Fix the inaccurate Life Cycle Assessment that ignores upstream and downstream GHG emissions associated with factory farm gas production.

230.3 3. Eliminate the 10-year "grace period" for factory farm gas producers.

230.4 4. Eliminate credit generation from factory farm gas projects that would have happened anyway due to other programs or investments

FOOD & WATER WATCH
Fight like you live here.

LEADERSHIP COUNSEL FOR JUSTICE & ACCOUNTABILITY

We demand a future free from the clutches of Big Oil and Big Ag, and we urge Governor Newsom and CARB to prioritize the well-being of Californians over the profits of corporations looking to exploit the climate crisis.

Governor Newsom, CARB has the power to shift California towards truly clean energy solutions and remove the incentives for factory farms to produce and sell dirty credits that enable the continued reliance on Big Oil and combustion fuels. You have spoken eloquently about the need to take bold climate action rooted in justice, but this is one major area where California not only falls short, but has a policy that is making the climate and pollution crisis worse. You can change this. We appreciate your attention to this critical matter and look forward to seeing decisive action taken to reform the LCFS and protect the communities most affected by its current flaws.

RE: ChargePoint Comments on Proposed Low Carbon Fuel Standard Amendments

Thank you for the opportunity to submit comments on the proposed amendments to the Low Carbon Fuel Standard (LCFS) issued on December 19, 2023. ChargePoint has reviewed the Proposed Regulatio Order and appreciates the work of the California Air Resources Board (CARB) Staff to implement changes to LCFS that will advance investment in low carbon fuels and infrastructure in California.

About ChargePoint

Since 2007, ChargePoint has been committed to making it easy for businesses and drivers to go electric with one of the largest electric vehicle (EV) charging networks and a comprehensive portfolio of charging solutions. ChargePoint's cloud subscription platform and software defined charging hardware is designed internally and includes options for every charging scenario from home and multifamily to workplace, parking, hospitality, retail, corridor, and fleets of all kinds.

Summary of comments

•Expand the scope of "less intensive verification" for on-road electricity crediting to allow for networked charging stations tha meet certain requirements to be pre-approved. Entities that do not meet the requirements for less intensive verification could still undergo full verification.
•Remove the exemption for dedicated parking spaces under multifamily crediting and allow owner/operators to claim credits o all stations at multifamily locations.
•Regarding the MHD-FCI provision: (1) relax the siting requirement to within 5 mi of a FHAA corridor, (2) reduce the minimum kW nameplate capacity to 200, (3) consider shortening the FCI crediting window to 7 years, and (4) roll unutilized LD-FCI

capacity into the MHD-FCI provision to increase deployments.
•Take greater action to stabilize the credit market, either throug
supply-side intervention or more stringent carbon intensity targets. Increase the step down to 10%.
•Modify the Automatic Acceleration Mechanism (AAM) formula to trigger once the credit bank exceeds three-fifths of the prior year's deficits, instead of three-fourths.

Requirements for less intensive verification

The inclusion of on-road electricity crediting in the verificatio program is not a small lift and needs to be done thoughtfully. Therefore, we suggest CARB consider putting off including electricity verification in this rulemaking given the many other issues being considered. However, if CARB believes that on-road electricity reports must undergo third-party verification under th amended regulation due to largescale risk of misreporting (which t our knowledge, there is currently no evidence of), CARB should lea on existing technology, standards and relevant regulations when designing verification. To that end, we appreciate CARB's inclusio of a "less intensive verification" pathway in the proposed rules but believe that this does not go far enough. The less intensive verification pathway should be expanded to consider the following

The EV charging network is fundamentally different than the traditional point-source liquid fuel supply network: whereas liqu fuels originate from fewer and larger sources (refineries), EV charging stations are significantly more disaggregated, where each point (or charger) in the network represents a small amount of potential fuel supply which renders physical site visits across th whole network impractical and costly. For meter accuracy assuranc CARB should instead lean on accuracy thresholds that already exis in the industry, such as those within the California Type Evaluation Program (CTEP), which require that level 2 (L2) EV charging meters meet an accuracy threshold of ±1% upon manufacturing and calibration and ±2% over its useful life, while level 3 (L3) meters must meet a ±2.5% accuracy upon manufacturing and calibration and ±5% over its useful life. The CTEP standard is already being utilized by the California Division of Measurement Standards (DMS), the entity tasked with ensuring the accuracy of commercial devices, including EV charging stations. DMS sets standards to promote fair competition and ensure consumer protection and points to the CTEP as the metrological accuracy standard that chargers installed after a certain date must meet to be used for commercial purposes. County Weights & Measures offices under the guidance of statewide rules established by DMS, serve to enforce the standards by conducting periodic site visits to verify the accuracy of fueling stations.

Recommendation: CARB should pre-approve charging stations that meet CTEP's meter accuracy standards for participation under the less intensive verification pathway.

Pre-approval would mean exempting eligible charging station models from site visits and third-party meter testing based on that model's meter accuracy substantiation. CARB could publish a list of exempt charging station models that meet CTEP's meter accuracy standards for credit generators' reference. This is similar to the approach taken under Canada's national Clean Fuels Regulation. Otherwise, the existence of the DMS framework for assessing and enforcing charger accuracy would render additional site visits and meter testing, even only in half of the years as currently proposed under the "less intensive verification" pathway, under the LCFS program duplicative and punitive on the industry, particularly for small owner/operators .

With assurances around charging station meter accuracy ensured by the accuracy standards embedded in CTEP, the final step to less intensive verification would be a "desktop" review of the data in the reports. The scope of the desktop review would be to ensure that the data in the quarterly reports submitted through the LRT matches the data that was output from the charging network. EV charging networks are underpinned by extremely accurate (down to the watt-hour), real-time data in a way that traditional liquid fuel networks are not . Networked EV charging provides a near constant stream of data that can be verified against reported charging activity.
There are a number of standards, practices, technologies and processes charging network operators adhere to to ensure the accuracy of data. For example, ChargePoint complies with several

standards to ensure that the data reported by the station maintai
its accuracy as it is transferred from the station to the cloud, and that any data anomalies are detected and removed before being reported. Many network operators also maintain compliance with Payment Card Industry Data Security Standards (PCI DSS) to ensure an accurate and secure environment for network transaction data. CARB could pre-approve networks that meet certain standards for u
under the less intensive verification pathway, similar to pre-approving charging station models based on meter accuracy. Standards and documents required for pre-approval could include SOC2 reports and/or PCI certification.

Our recommendations for the less intensive verification pathway a
not necessarily meant to be prescriptive, but rather to point out how existing technologies, best practices, and standards already widely adopted in the industry should be incorporated into the pathway. This will greatly minimize administrative costs for an industry that is still scaling. This is also the general approach taken under Canada's national program. We urge CARB to not try an
reinvent the wheel re: on-road electricity verification. Reportin
entities that do not meet the requirements for less intensive verification would still be able to undergo full verification.

Credits for non-residential chargers at multi-family residential properties.

ChargePoint strongly supports the proposal to allow FSE owners to generate credits for stations installed at multifamily properties This change will create more revenue opportunities for property owners that install chargers at multifamily locations, and critically, incentivize more deployment of chargers for residents of multifamily homes, a market segment that has historically lack
investment.

Recommendation: remove the exemption for dedicated parking spaces and allow owner/operators to claim credits at all multifamily locations.

While we fully support the proposal to treat multifamily creditin
the same as non-residential, we do not agree with the proposal to treat chargers in dedicated parking spaces differently. Not only will the exclusion of restricted parking spaces be extremely

difficult to track, but it also arbitrarily distinguishes credit generation based on a residence's parking arrangement. Recent analysis by the CEC indicates that expanding the range of charging options available in the parking lots of multifamily housing will ensure charging is not a barrier to EV adoption. Increasing home charger access for residents of multifamily homes must be a priority to equitably meet the routine charging needs of more EV drivers, and for this reason, we strongly support this change by CARB.

Residents of multifamily housing are generally not able to install conventional home charging without financial assistance from the building owner. This is because charger installation at multi-family properties often requires upgrades to shared electrical panels and running conduit across common parking areas A single household of a multifamily residence is generally unable or unwilling to shoulder the high cost of charger installation themselves. In other words, there is a "split incentive" affecting multifamily properties in which a property owner must pay for and organize installation, while the chargers may only benefit the fraction of residents who drive EVs at the time of the upgrade.

In fact, there is a case to be made that chargers in dedicated multifamily residential parking places may have the most impact on those residents switching to electric and should therefore be supported by the LCFS through the ability to generate value from credit generation. This is especially true considering CARB's proposal to redirect funds from the Clean Fuel Reward (CFR) progra towards MHD EVs (which we also strongly support). Whereas before, CFR value was generated by residential (including multifamily) charging so it made sense to return some of that value to individual EV drivers via LD EV rebates. If CFR value will now go towards MHD EV rebates, it only seems right to allow owner/operators of multifamily chargers to retain the value of the LCFS which can help finance or buy down the cost of the station.

Medium and heavy duty (MHD) Fast Charging Infrastructure (FCI) credits

ChargePoint strongly supports the addition of the MHD FCI provision. While the passage of the Advanced Clean Fleets and Advanced Clean Trucks regulations are expected to create greater demand for MHD EVs, infrastructure development to support these vehicles remains economically challenging due to the lack of MHD vehicles on the road today and the expectation that it will take time for the market to grow. The expansion of FCI credits for both private and shared MHD FCI is a much-needed intervention to commercialize charging infrastructure and help stimulate investment for this segment. ChargePoint also appreciates the inclusion of shared private fleet chargers in this program. Nonetheless, a few revisions to the rules for MHD FCI credits will allow the program to support the nascent MHD refueling market more effectively.

Charging hubs for MHD vehicles are likely to require several megawatts of power for each site. These projects will in most case require significant distribution grid upgrades by the utility. Due to the complex factors that inform site selection for MHD charging sites, including but not limited to access to travel corridors, proximity to vehicle routes, distribution grid capacity, and land acquisition, it remains unclear which locations will be the most efficient to locate private or shared MHD charging hubs. For this reason, overly narrow location requirements for MHD FCI sites may impede development by eliminating projects that would otherwise be ideal due to ample grid capacity. While we understand CARB's inter for the FCI program to focus charger deployment in alternative fue corridors for the purposes of accessibility and equity, station owners and drivers would benefit from less stringent geographic limitation.

Recommendation: relax the geographic siting requirement to 5 mi from a FHAA fuel corridor to provide flexibility for site selection.

The amendment proposal establishes a minimum power level of 250 kW for chargers serving sites that receive MHD FCI credits. The minimum power level established for MHD-FCI sites should consider today's MHD fleet needs, as well as the anticipated needs of the future. For most MD vehicles on the road today, 200 kW is more tha sufficient for the vehicle's needs and helps lower overall system costs (relative to 250 kW or greater). Therefore, ChargePoint recommends that CARB reduce the minimum power level for each charger serving MHD FCI to 200 kW, as this minimum is sufficient t meet the market where it is today, as well as accommodate the need of coming MHD vehicles.

Recommendation: reduce the minimum kW eligibility requirement to 200 from 250.

Regarding the MHD-FCI crediting window, while some sites will neec a 10-year window to recoup capital costs, a longer window could encourage overbuilding and disincentivize utilization in the shor to mid-term, both of which are not ideal for the market. We belie a crediting window closer to 7 years will suffice for the majorit of projects and encourage sites to build for utilization sooner rather than later. This should also free up more capacity under tl MHD-FCI cap sooner which will open up capacity for more sites ove time.

Recommendation: consider shortening the MHD-FCI crediting window 1 7 years.

The CEC reports that as of 2023, California has over 9,000 DCFC ports in operation and is ahead of schedule to meet its port deployment target of 10,000 ports by 2025. ChargePoint believes I FCI revenue has successfully accelerated investment in the market for public DCFC and is partly responsible for the state's success in this segment. When paired with the continued growth of LD EV sales in California, it seems clear that continued investment in LD-FCI can sustain itself without greater support from FCI credit By contrast, the MHD segment would benefit from greater FCI suppo because it is underdeveloped relative to the state's goals. The C estimates that by 2030, California's 155,000 MHD EVs will need about 114,500 public and shared chargers.

To further accelerate the market for MHD electrification, we recommend CARB rollover any unused LD-FCI credits into the MHD ca to allow for greater investment/deployments in this segment (more on this below).

Revised Clean Fuel Reward Program

ChargePoint supports the proposal to redirect funds from the CFR program to make MHD EVs more cost-effective. The current framewor of allocating CFR funds towards LD EV rebates has long since lost efficacy as the rebate amount is not salient to prospective EV drivers to the point where it induces additional purchases.

ChargePoint is pleased to see this change as the current state of the MHD EV market is more in need of funding than the LD segment.

Light duty FCI credits

The proposed regulation establishes a transition plan to reduce F(crediting available for LD DCFC applicants. Among other changes, the proposal amends the cap for LD FCI credits to 0.5% of prior quarter deficits, a reduction from the previous cap of 2.5%. ChargePoint supports this change and agrees that LD-FCI credits should be capped to no more than 0.5% to focus infrastructure crediting on the more nascent MHD EV market. As discussed previously, ChargePoint believes MHD-FCI should be the priority ar recommends CARB consider further reduction in the availability of LD-FCI credits in favor of a higher cap on MHD-FCI credits.

Should the LD-FCI pathway remain open beyond 2025, ChargePoint believes it would be premature to limit eligibility to stations with a nameplate capacity of 150 kW or more in light of the other proposed changes to the pathway. A station capacity minimum of 15(kW combined with the change to how FCI charging capacity is calculated as well as the extension of the crediting timeline to 1 years will together incentivize overbuilding sites without regard to utilization solely because of FCI credits.

New carbon intensity benchmarks

In the weeks following CARB's release of its amendment package in mid-December, the spot market for credit prices declined ~20% (falling from $70/credit to a low of $57/credit). In that time, th market incorporated CARB's proposal of a 30% carbon intensity (CI) target by 2030, along with the proposed changes to the supply side and determined that this market will continue to be oversupplied. Without more ambitious CI targets and/or clearer steps to curb biofuel production with uncertain greenhouse gas benefits (Murphy Wook, 2024) , it is apparent that this market will continue to be oversupplied and credit prices will remain low for the foreseeable future.

In prior conversations with CARB staff, we have come away with the understanding that CARB assumes the LCFS program, and the potentia revenue it affords, does not factor into investment decisions for

EV project operators (fleets, charging operators, etc.) and therefore investment in EVs and charging infrastructure is agnost: to LCFS credit prices. We do not agree with this assumption. Advanced Clean Cars, Advanced Clean Trucks, and Advanced Clean Fleets do not directly address or fund charging infrastructure. Tl LCFS program can, and often does, provide an important revenue stream for EV project operators and can be the difference between project penciling or not. Project developers, operators, and investors in the EV space operate similarly as those in other spaces: they evaluate all available costs and revenues when assessing a potential project and often make decisions based on expected net cashflows. The difference between expected 5-year LCI revenues on a L2 station with roughly average utilization in a world where credit prices hover in the ~$60/credit range vs ~$150/credit is significant. In the former, expected 5-yr LCFS revenues do not amount to enough to influence the business case, whereas in the latter, LCFS revenues offset a significant portion of the cost of the station and can even be leveraged for project financing.

As electrification has the most potential for long-term deep decarbonization of transportation, we urge CARB to account for the impact that sustained low credit prices may have on transportatio electrification investments. Without clearer steps to limit crop-based biofuels - or specific carve outs for on-road electricity credits, like how some state Renewable Portfolio Standards set specific carve outs for solar - investments in charging infrastructure and electric fleets will be crowded out under the program by the continued surplus of biofuel credits in the market.

Recommendation: in lieu of some sort of cap on crop-based biofuel: we believe the 2030 CI target needs to be increased to 32.5% to 3! and the stepdown needs to be increased to 10% to raise price expectations to the level needed to usher in more investment.

Automatic Acceleration Mechanism (AAM)

ChargePoint supports the proposal to establish the AAM but recommends that CARB make the mechanism stronger. As proposed, the AAM would not have been triggered in any of the years after the 2018 amendments. These years include 2022, a year when the credit market price declined by ~50%. The AAM should be designed specifically to counteract this type of negative price movement, s a mechanism that would not have reacted in 2022 is not strong enough.

To strengthen the mechanism, we recommend that ARB amend the first condition of the AAM to be reached when the cumulative credit bank is greater than three-fifths of the deficits generated over the same calendar year rather than the current condition set at three-fourths. With this update the AAM would have been triggered in 2022 but not any of the other years following the 2018 amendments. Since these other years saw price increases or modest declines, the new threshold suggests a balanced mechanism that reacts only to large price decreases.

Conclusion

ChargePoint appreciates the opportunity to submit comments to CARB on the Proposed Regulation. We stand ready to work with CARB Staff to implement the changes discussed in these comments, particularly to ensure that the process of verification is administratively efficient for the on-road charging market.

Respectfully,

Evan Neyland
Senior Manager, Carbon Markets

Matthew Botill
California Air Resources Board
1001 I Street
Sacramento, California 95814

Re: SJI Renewable Energy Venture's Comments on the Low Carbon Fuel Standard (LCFS) Proposed Amendments

Dear Mr. Botill:

SJI Renewable Energy Ventures focuses on clean energy development and decarbonization via renewable energy production and energy management activities. Through these activities, we are committed to the nations transition to a carbon-free economy and, accordingly, has developed a comprehensive clean energy plan that includes being a leader in the development of dairy digestor projects in the United States. SJI works closely with the Environmental Protection Agency (EPA, California Air Resources Board (CARB), local dairy farmers, utilities, and surrounding communities to directly reduce greenhouse gas (GHG) emissions.

SJI Renewable Energy Ventures thanks CARB for the opportunity to take part in the many workshops and conversations during the development of the Proposed Amendments (Proposed Rule) and the Initial Statement of Reasons (ISOR). We respectfully submit the following comments on the Proposed Rule and ISOR. Through the enhancement of the program's goals, CARB will be best suited to address GHG reductions from transportation fuels. The following comments will focus on avoided methane crediting, increased program ambition, credit true-up, and deliverability. Additionally, SJI Renewable Energy Ventures supports the technical comments submitted by the RNG Coalition and additional comments from the American Biogas Council.

Avoided Methane Crediting

SJI Renewable Energy Ventures has invested in projects that will cost-effectively achieve immediate fugitive methane emission reductions from agricultural operations. The lifecycle GHG emissions

accounting that underpins the LCFS program recognizes the benefit of these avoided methane emissions that would have otherwise occurred absent investments like those made by SJI Renewable Energy Ventures. The RNG projects that we are developing will likely be certified at deeply negative carbon intensity values because of this explicit and immediate benefit to methane emission reductions at

SJI Renewable Energy Ventures

agricultural operations. The Proposed Rule seeks to utilize a fixed year phase-out of avoided methane crediting. Avoided methane emissions is a vital, fact-based, part of the life cycle assessment and its' inclusion in carbon intensity scores is consistent with internationally recognized carbon accounting. The LCFS program has been extremely successful in reducing overall methane emissions. SJI Renewable Energy Ventures strongly encourages CARB to
232.1 continue to utilize the current method of acknowledging avoided methane emissions and the
use of Argonne National Laboratory's GREET model.

Increased Program Ambition

SJI Renewable Energy Ventures is encouraged to see that the Proposed Rule sets forth more ambitious carbon intensity targets. As mentioned in previous comments, stronger CI reduction targets is an essential element to driving down GHG emissions. Given the current LCFS credit surplus, seen over the last few years, a larger step-down in the carbon intensity benchmark is critical to signal market support and increase investments. We support the ABC's comments on
232.2 this topic. Specifically, (1)"by increasing the step-down as well as pulling forward the effective
232.3 date for triggering the Auto Acceleration Mechanism (AAM) CARB can "recapture" reductions in
GHG emissions that will otherwise be lost with the current proposal. Doing so will also send a clear, and supportive market signal to continue investments in clean fuels that would otherwise be constrained and subdued by the current proposal." Additionally, we support the RNGC on this policy topic through their comments. (2) "Increasing the program's benchmarks to set a 25% CI reduction below the 2010 Baseline in 2025 would be sufficient to begin to draw down the credit bank, reestablish a demand for additional expansion in low carbon fuel supply, and therefore drive additional greenhouse gas abetment. Further, starting the step-down as soon as
232.4 possible and avoiding unnecessary bank build is crucial. We recommend that CARB target the
step-down to occur on 7/1/2024 to a level of 25% below the 2010 baseline and maintain that level through 12/31/2025 (assuming CARB elects to retain the updated 2010 diesel baseline value and that the necessary administrative steps can be accomplished on this timeline)." Finally, we
232.5 strongly encourage CARB to continue to target *at least* a 30% CI reduction by 20230.

Deliverability Requirements/Book-and-Claim

Book-and-Claim has allowed the LCFS to become one of the most successful decarbonization programs in the country. California has benefitted from the use of indirect accounting through national investments and participation in the LCFS. In return, the program has been highly successful at reducing GHGs, a goal we all support. SJI Renewable Energy Ventures respectfully requests CARB continues to allow for this type of accounting to ensure GHG reductions
232.6 continue at a successful rate. Although the policy concept of new deliverability requirements
has been mentioned throughout the stakeholder process, specifics never emerged. We strongly request that deliverability language, in the Proposed Rule, be removed to allow for greater stakeholder engagement on the specific topic.

(1) American Biogas Council Comments on the Proposed Amendments to the Low Carbon Fuel Standard
(2) RNG Coalition's Comments on Low Carbon Fuel Standard Initialt Statemen of Reasons

SJI Renewable Energy Ventures

Credit True-Up

232.7 We support the inclusion of a credit true-up after Annual Verification. An appropriately implemented true-up policy will ensure that that all GHG benefits are accounted for. However, as drafted in the Proposed Rule, we believe there needs to be a correction. As drafted, it appears the Proposed Rule will NOT allow true-ups during the temporary pathway period. During the August 2022 LCFS Workshop, CARB Staff proposed providing a credit true up to correct for under crediting to pathway holders *only* during the period where a project is using temporary CI scores at the outset of their credit generation. The material used during the Workshop provided that such a limited true up would help reduce the pressure on CARB from developers to process LCFS applications quickly.

Due to factors such as weather and herd size changes, dairy manure digestors can experience drastic changes in gas production throughout a given year. With the carbon intensity of the gas being calculated against the quantity of avoided methane emissions, the variations in biogas production results in changes in a digestor's CI score every year. We believe, if digestors were allowed to fully true-up the LCFS credit generation to the actual CI score (based on actual GHG performance data), any issues the Proposed Rule is trying to address, would be resolved.

Conclusion

SJI Renewable Energy Ventures appreciates the opportunity for continued participation throughout this rulemaking process. A process that is critical to achieve the decarbonization goals that we both share. We remain committed to providing RNG to the California LCFS market and helping to reduce methane emissions, improve animal manure management in agricultural communities and decarbonize California's transportation sector. We thank CARB for your continued work toward this end and look forward to a robust and effective LCFS update.

Sincerely,

Kyle Nolan

Subject: Low Carbon Fuel Standard – Light-Duty Vehicle Residential Base Credits

The Alliance for Automotive Innovation (Auto Innovators) and our members appreciate the opportunity to comment on the proposed changes to the Low Carbon Fuel Standard (LCFS).[1] Automakers and this association have long supported reductions in the carbon content of liquid fuels. Low carbon liquid fuels are an additional pathway for reducing transportation GHG as they are (1) technically feasible today, (2) the only viable decarbonization solution for the legacy vehicle fleet, (3) an important complement to vehicle electrification over a long transition, and (4) affordable for consumers whose needs or budgets require different solutions. Since the vast majority of the 280 million vehicles on U.S. roads today have an internal combustion engine, decarbonizing liquid fuels on a well-to-wheel basis would yield immediate benefits for lowering the carbon intensity of transportation energy.

233.1 While we support the LCFS, we do not support the changes that would take revenue generated by light-duty (LD) electric vehicle (EV) residential charging and use it to subsidize utilities and businesses operating medium- and heavy-duty vehicles. Instead, this funding should be used exclusively to develop the light-duty and residential EV market through infrastructure, vehicle incentives, and public education.

[1] California Air Resources Board. (2024). Notice of Public Hearing to Consider Approving for Adoption the Proposed Low Carbon Fuel Standard Amendments. Retrieved January 26, 2024, from https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_notice.pdf

1. Light-duty EV market

The transition to zero emission vehicles (ZEVs)[2] for light-duty vehicles (LDVs) is far from complete. Despite a 25% market share for LD EVs in 2023, substantial progress is needed to meet the Advanced Clean Cars (ACC) II requirements of 51% ZEV in 2028, 68% ZEV in 2030, and 100% ZEV in 2035. Without vastly improved LD residential and public infrastructure, there is a high probability the LD EV market growth will stall long before these levels are met.

Current new EV buyers are far more likely to be affluent single-family homeowners who can both afford the higher cost of EVs and have ready access to reliable, low-cost, and convenient home charging. While most new car buyers might be affluent single-family homeowners, the transition to 100% ZEVs in ACC II requires not just "most new car buyers" but "all new car buyers."

Moreover, meeting the ACC II ZEV sales mandate also requires used car buyers (including the third, fourth, and fifth vehicle owners, who are less likely to have access to home charging) to embrace ZEVs. Access to home charging that most current ZEV buyers enjoy dramatically lowers the need for public charging. As the ZEV requirements increase under ACC II in the next few years, the portion of drivers that do not have home charging increases and these drivers will be forced to rely on public charging, which is currently inadequate, unreliable, inconvenient, and expensive compared to home charging.

Thus, to ensure the successful full transition to EVs outlined and required under ACC II, funding generated by residential EV charging should be used exclusively to develop the LDV EV market through infrastructure, vehicle incentives, and public education.

2. Reestablish California Clean Fuel Rewards administered by automakers for LD EVs

233.1

Auto Innovators recommends reestablishing the California Clean Fuels Reward (CCFR) program as a point of purchase incentive. Less than four years ago, this program was established with unanimous support from automakers, utilities, and CARB to provide a point of purchase reward of up to $1,500 for new EVs. The CCFR was reduced to $750 and then eliminated altogether on September 1, 2022. This program incentivized residential customers – *the very customers who generate the LCFS credits that fund this program* – to choose electricity rather than gasoline to fuel their vehicles. Moreover, the CCFR was provided at the time of purchase, avoiding the weeks- or months-long wait associated with other rebate programs. It also provided an ongoing

[2] ZEVs include battery, plug-in hybrid, and fuel cell electric vehicles (BEV, PHEV, and FCEV, respectively).

233.1 revenue stream, rather than dependency on the annual state budget allocation. Lastly, it was one of the last remaining financial incentives in California for LDVs. Its demise came at a time when ZEV sales were becoming more dependent on purchases by mainstream consumers. These consumers need more encouragement to purchase an electric vehicle than early adopters.

233.2 Auto Innovators continues to support CCFR directed to LD EVs. However, rather than providing the LCFS credits to utilities, participating EV automakers and a third-party administrator selected by CARB (CFR Program Administrator) should administer the program and provide the EV Purchase reward. Automakers have decades of experience administering vehicle rebates and can do so far more efficiently than utilities.

To provide a stable and predictable EV incentive, CARB and automakers should set the CCFR EV purchase reward annually based on estimated revenue from LCFS credit generation from residential EV charging. Unlike utilities that require minimum cash reserves (around $10 million) and thus needed to quickly change the CCFR program, participating automakers could continue the CCFR throughout the year and then adjust the CCFR reward in subsequent years.

3. Equity programs should receive 45% of residential EV charging revenue

233.3 Automakers recognize the transition to an all-electric future will not happen without the full participation of equity communities. In fact, equity communities represent the most difficult segment in the transition to all LD EVs due to historically lower incomes, lack of reliable, low-cost, convenient residential charging, need for reliable transportation, and potentially longer commutes. Ironically, these communities stand to benefit the most from LD EVs, with the proper support in place. CARB should revise the regulation to ensure that at least 45% of residential EV charging LCFS credit revenue is directed to equity community LD EV projects, including:

- LD EV multi-family residential and public infrastructure.
- Workforce development related to LD EV market development, including LD EV residential and public infrastructure installation, operation, maintenance, and repair and LD EV sales, maintenance, and repair.
- Additional rebates for new and used LD EVs in equity communities.
- Rebates for residential charger installation in equity communities.

233.3
- Vouchers for public charging to equity community members.

4. Automakers Producing EVs Should Receive Base Residential Charging Credits

No industry is investing more than automakers to develop the EV market. By 2030, the auto industry will invest more than $500 billion globally in everything from critical minerals and critical mineral processing, to battery cell and pack production, to vehicle development, certification, and production, to charging stations and consumer education. Moreover, automakers are developing telematics, vehicle-to-home (V2H), and vehicle-to-grid (V2G) technologies that benefit the electric grid. Nonetheless, automakers are excluded from receiving any of the base residential charging credits generated by their investment.

CARB regulations should provide automakers "pre-approved" uses for the credit proceeds like those provided to the utilities. For example, the following pre-approved projects parallel those provided for non-equity utility holdback credits (c)(1)(A)5.b.:

233.2 cont

i. Investments to improve EV efficiency, charging time, and EV charging convenience.
ii. Investments in V2H and V2G technology development including
    1. Encouraging the optimization of EV charging through education and technology to improve the ability of customers to charge at times of lowest cost.
    2. Providing incentives to encourage drivers to participate in managed charging, demand response, V2H, or V2G programs.
    3. Supporting the development and use of vehicle bidirectional charging.
    4. Other innovative approaches to promote and manage EV charging and discharging to benefit customers and the grid, including methods to reduce battery degradation from V2H, V2G, and fast charging events.

iii. Hardware and software that reduces the cost of EVs.

5. Revenue FROM light-duty EV owners TO light-duty EVs

233.4

As noted above, rather than subsidizing electric utilities or businesses operating medium- and heavy-duty vehicles, revenue generated from LD EV residential charging should be used to grow the LD EV market. Thus, we recommend eliminating "pre-approved projects" in the proposed regulations that provide funding for changes not related to the LD EV market. Specifically, we recommend eliminating the following pre-approved projects recognizing that utilities could still propose and seek approval of these projects.

233.4 cont

- Electrification of drayage trucks and other M/HD EVs or off-road vehicles, including school and transit buses.
- Incentives for using public transit, including car and ride share, public transit and school bus (including battery swap programs).
- Micro-mobility solutions (eBikes, eScooters, eMotorcycles, etc.).
- Investments in grid-side distribution infrastructure for M/HD EVs.
- VGI projects (EV charging education, incentives to encourage drivers to participate in managed charging, deployment of bi-directional charging equipment, or other innovative approaches to promote managed charging).
- Hardware and software that reduces the costs or avoids updates to infrastructure.

6. Conclusion

Again, we sincerely appreciate the opportunity to work with CARB on proposed changes to the LCFS regulations. Please don't hesitate to contact me if you have any questions or need additional information.

Sincerely,

Dan Bowerson
Vice President, Energy & Environment

Board Comments Home

Raízen Energia S.A.
Av. Brig. Faria Lima, 4100 - Itaim Bibi,
São Paulo - SP, 04538-132

February 20, 2024

The Honorable Liane Randolph
Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814
(Comments submitted electronically)

Dear Chair Randolph,

We appreciate the opportunity to comment on the Proposed Low Carbon Fuel Standard (LCFS) Amendments.

Raízen is a company created from an independent Joint Venture with shared control between Shell and Cosan, which operates in the production and sale of sugar, bioenergy and bioeletricity. We have a fully integrated process that involves everything from the cultivation of the sugarcane to the production of sugar and ethanol and the logistics of distribution and marketing of these products. We are currently the largest sugarcane-ethanol producer globally, and a unique holder of second-generation ethanol technology operating in a commercial scale.

We would like to start our comments by recognizing CARB's technical staff's diligent work and willingness to engage with stakeholders in the process of updating the LCFS regulations through this rulemaking.

We continuously seek to manage and improve the carbon footprint of our products by diversifying our renewable energy portfolio, with the objective of delivering decarbonization solutions to the market. We increasingly invest to support the mitigation of climate change and the global energy transition. Markets that aim to decarbonize the transportation sector and have a premium policy related to biofuels, such as LCFS / CARB (Low Carbon Fuel Standard / California Air Resources Board), are naturally of interest to Raízen for the commercialization of our biofuels. We pride ourselves for being a committed stakeholder to CARB's LCFS program for a long time and for always offering reliable and trustworthy data on the ethanol sector in Brazil. Raízen has also supplied a significant amount of ethanol to California in recent years.

While acknowledging the advancements that the draft proposal brings, we would like to highlight some points we believe may improve the proposed amendments to the LCFS program.

1. **Comments on Sustainability Requirements for Crop-Based Feedstocks (Section 95488.9 (g), Appendix A-1.1)**

We understand the pivotal role sustainability certifications play in assuring a fair-trade system combined with sustainable development. Raízen, for instance, has its plants certified by certification schemes, such as Bonsucro and ISCC. Recently, we were the first ethanol producer in the world to be certified with the ISCC CORSIA Plus certification.

In addition to certifications, geographic traceability is maintained for the sugarcane we process, whether sourced from our own operations or from third-party suppliers. This entails the possession of shapefiles delineating the locations of the farms and plots from which we procure or cultivate sugarcane. Our differentiated management of the supply chain enables us to ensure the geographic traceability of our raw materials under the highest sustainability standards in production.

234.1 Based on our experience complying with and promoting sustainable practices, we regard such certifications (RSB, ISCC and Bonsucro) as internationally recognized in this field. Not to mention Renovabio, in Brazil. We would therefore encourage CARB to carefully consider these established certification schemes and taking steps to recognize and align with these respected approaches thus avoiding duplication of efforts and placing additional burdens on companies that intend to have trade flows with the state of California and would need to abide by LCFS' sustainability criteria.

Finally, for tracking crop-based feedstock in the supply chain, Raízen strongly recommends the mass-balance approach, a system widely recognized by sustainability certification schemes. The mass balance approach is widely utilized due to its simplicity, particularly within value chains that involve multiple suppliers. In the mass balance tracking model, materials, or products with a set of specified characteristics are mixed according to defined criteria with materials or products without that set of characteristics. Acknowledging the relevance of international reliable certification schemes, the mass balance approach would require fewer resources for biofuel producers, CARB staff and certification bodies. It also ensures transparency through clear documentation. This approach provides feedstock buyers with greater certainty about the sustainability criteria.

2. **Comments on Tier 1 for Second-Generation Ethanol (E2G)**

234.2

Raízen is the unique holder of second-generation ethanol technology operating at a commercial scale. We have one E2G plant operating since 2018 (Costa Pinto) producing at full capacity (~7,925.161,6 gallons/year), as well one recently delivered new plant under construction and 8 more to be constructed soon. It is important to highlight that the E2G production is entirely bagasse-based, tackling climate change with a less carbon intense fuel compared to conventional biofuels, and bringing disruptive technology, as well providing good local jobs and economic growth.

234.2

Looking at this expansion plan and benefits of the second-generation ethanol, Raízen's E2G production will significantly increase during the coming years. **Therefore, we strongly advocate for CARB staff to incorporate the second-generation ethanol pathway into Tier 1.** Recognizing the hurdles in integrating new pathways, we stand ready to support CARB staff by providing valuable operational data.

3. Comments on Backhaul Energy Intensity (Section II-C, Appendix B)

234.3

Raízen echoes Shell's assertion that **the addition of backhaul energy intensity to ocean tankers for Brazilian sugarcane is not a universally applicable condition**. This situation does not apply to ethanol transported from Brazil to the US. Raízen can provide evidence of its trading logistics, as it has done in the past, and is pleased to collaborate with CARB staff again to offer further information.

4. Comments on Tier 1 CI Calculator

Firstly, we want to acknowledge CARB's technical staff for their continued efforts and willingness to collaborate with us in the ongoing process of updating the calculator for sugarcane ethanol. However, CARB is faced with a significant responsibility, one that will influence transportation policy for years to come, not only in the US but also in other jurisdictions across the United States and internationally. We are eager to continue contributing to this endeavor.
As we discussed last year during the amendment process of the Draft Tier 1 Calculator, we would like to reiterate some of our comments regarding the assumptions incorporated in the Tier 1 CI Calculator. **Recognizing the potential challenges faced by CARB staff in reviewing Tier 2 applications, we respectfully propose the integration of the following requests into the Tier 1 calculator**. This strategic enhancement aims to optimize efficiency and mitigate administrative burdens associated with Tier 2 evaluations, aligning with our commitment to facilitating smoother processes within regulatory frameworks.

a. N_2O emissions from applied N

The emission factor for direct N_2O emissions from nitrogen inputs, as previously outlined in CA-GREET 3.0, stood at 0.01 kg-N_2O-N/kg N-fert applied to soils, as sourced from the IPCC (2006). In the current version of the CA-GREET 4.0, this figure has been revised to 0.00895 kg-N_2O-N/kg N-fert based on Wang et. al (2012). But no updated was included in the Tier 1 CI Calculator. Raízen acknowledges the efforts of CARB staff in updating this value in CA-GREET 4.0.

Despite this updated science evidence, it is worth noting that this adjustment may still not accurately reflect the Brazilian reality, and **the IPCC generally recommends prioritizing regional data whenever available.**

Carvalho et al. (2021)[1], in a recent publication, conducted a comprehensive study based on 14 relevant publications reflecting current nitrogen fertilization practices in South-Central Brazil's sugarcane industry. Their research is grounded in data gathered from field studies conducted across 17 experimental sites. Importantly, they meticulously accounted for background emissions of N_2O EF, incorporating over 86 reported values. Notably, the study encompasses N_2O EFs derived from sugarcane cultivated under green mechanized harvesting, which dominates over 95% of the sugarcane cultivation area in the South-Central region of Brazil.

Carvalho et al. (2021) found the average N_2O–N EF of 0.006 kg N2O-N/kg N applied, considering all N fertilizer sources, for the sugarcane ratoon, which receives most of the N application of the sugarcane areas, and represents 80% of the sugarcane cycle and 89% of the total amount of N fertilizer consumed considering the entire sugarcane mill. **The EF value recommended by Carvalho is 33% lower than the value proposed by Wang et at. (2012).** The value identified by Carvalho is justified by good drainage properties of the deep Oxisols soils, where sugarcane is commonly cultivated in Brazil.

Hence, the review of in situ N_2O–N EF measurements from sugarcane in Brazil indicates values below the default currently proposed in the CA-GREET 4.0, and notably lower than those observed in many sugarcane areas in other regions worldwide. IPCC (2019) values, used in the current Tier 1 CI Calculator, were
234.4 primarily derived from studies in Europe (34%), North America (28%), and Asia (19%), with Central-South America contributing with only 6−7% to the dataset. Therefore, does not represent the sugarcane reality in the region.

Raízen strongly recommends that CARB staff consider using the value of 0.006 kg-N_2O-N/kg N-fert for both CA-GREET 4.0 and Tier 1 CI Calculator, reflecting the specific conditions in South-Central Brazil's sugarcane production areas.

b. Unburned Mechanized Harvesting

Mechanized harvesting, which involves unburned methods, dominates the sugarcane harvesting landscape in Brazil's Center-South region, representing more than 95% of the total yield. This assertion is substantiated by both official governmental data[2] and primary data meticulously collected and

[1] *Carvalho, J. L. N.; Oliveira, B. G.; Cantarella, H.; Chagas, M. F.; Gonzaga, L. C.; Lourenço, K. S.; Bordonal, R. O.; Bonomi, A. Implications of regional N2O–N emission factors on sugarcane ethanol emissions and granted decarbonization certificates. Renewable and Sustainable Energy Reviews, 149 (2021), 111423. https://doi.org/10.1016/j.rser.2021.111423*

[2] Safra cana-de-açúcar, Center-South region: https://unicadata.com.br/listagem.php?idMn=4

audited by Renovabio in 2018 and 2019. Renovabio's findings further affirm the correlation between mechanized harvesting practices and the adoption of unburned methods. However, despite this evidence, the default values in the Tier 1 CI Calculator for sugarcane ethanol indicate a mechanization rate of just 80% in São Paulo state and 65% in other states, including the Center-South region.

As per CARB's request, an analysis utilizing remote sensing data was conducted employing the Mapbiomas-Fire[3] and UNICA's sugarcane area vectors. Data were processed in the Qgis software. For each sugarcane polygon, the percentage of intersection with the polygon of burned area from Mapbiomas-Fire was estimated. After the geospatial statistics calculations, the results were added to the attribute table of the vector, and state-level statistics were computed. Consequently, the total sugarcane area for 2020 was assessed at 10,280,528.7 hectares, of which 82,847.10 hectares were subjected to burning practices, accounting for less than 1% of the sugarcane area (**Figure 1**).

234.5

Considering the significant influence of this input on the calculator and the industry's substantial efforts to reduce emissions through modern harvesting techniques**, Raízen asks CARB staff to carefully review this information**. The implications of CARB's policies extend beyond California, impacting the wider country and the world. It's crucial that CARB's assumptions regarding mechanized harvesting accurately reflect Brazil's sugarcane production patterns, translating into improved carbon intensity for Brazilian ethanol.

We respectfully urge CARB to consider implementing an option for individual mechanization percentage, supported by evidence, within the Tier 1 CI calculator. If, for any reason, this is not feasible, we kindly request that the staff adjust the default mechanization values for Center-South Brazil to a value no lower than 95%. By doing so, CARB will align input more closely with actual practices.

[3] MapBiomas. MapBiomas Project - Mapbiomas-Fire Collection 1. 2022. Available at: https://mapbiomas.org/en/colecoes- mapbiomas-1?cama_set_language=en. *The Mapbiomas-Fire product was elaborated from mosaics of Landsat Satellite images, with 30 meters of spatial resolution, covering the years from 1985 to 2020, providing monthly and annual data of the burned areas in Brazil. The burned area estimation was carried out using artificial intelligence from machine learning algorithms in the Google Earth Engine platform. The algorithm was trained with samples of burned and non-burned areas, in addition with the burned area product of MODIS sensors (MCD64A1) and hot spots data from INPE.*

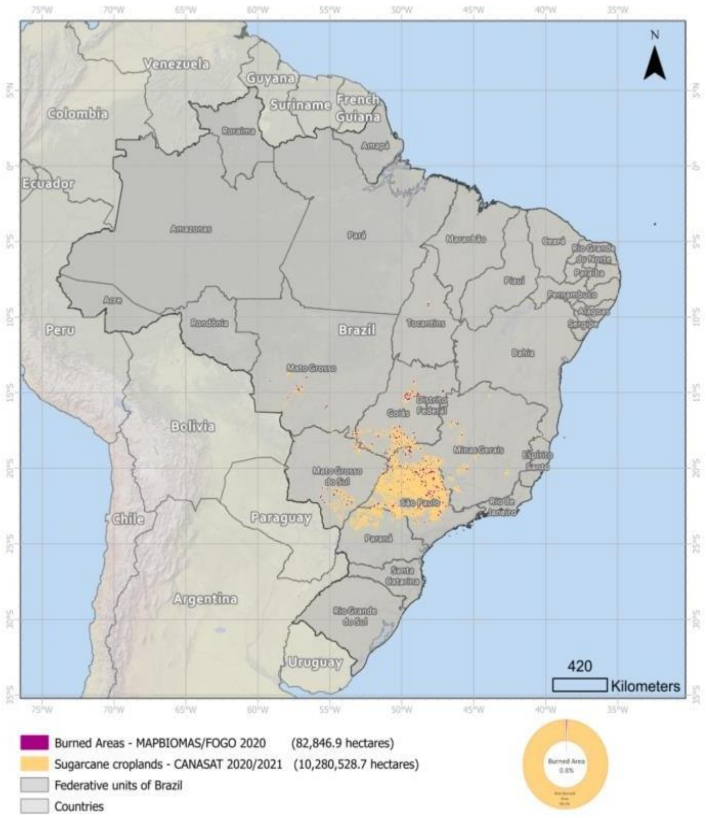

Figure 1. Intersection from the sugarcane area with the burned areas polygons from the MapBiomas-Fire for the center-south region of Brazil. Sources: Mapbiomas-Fire, Canasat.

c. Electricity Exported Credits

Sugarcane-based electricity in Brazil serves as a valuable supplement to hydroelectric generation, particularly during the dry season when water resources may be limited. Its contribution helps mitigate the need for natural gas- and coal-based electricity generation, thus promoting a more sustainable energy mix. **Raízen strongly recommends that CARB staff consider electricity export credits by acknowledging the displacement of the margin of the Brazilian electricity grid.** This should be based on sugarcane electricity's contribution to total thermoelectric generation during the dry
234.6 season in Brazil. This approach allows for the reallocation of energy dispatching primarily during this period, reducing the risk of deficit without worsening water reservoir conditions. Raízen disagrees with CARB's approach, which excludes energy exported in the off-season and fails to consider energy produced by cogeneration from third-party biomass. This can create a "double standard" where the rainy season is used to calculate the national electricity grid average but ignored when CARB excludes export electricity credits generated in the off-season months. Both approaches significantly impact the carbon intensity (CI) value of ethanol mills in Brazil.

For a more detailed exploration of electricity production and dispatch in Brazil, please refer to **Annex A.**

d. Straw Yield

Raízen greatly appreciates CARB staff's consideration in updating the sugarcane straw yield in the CA-GREET 4.0, reducing it from 0.24 t/t cane (dry basis) to 0.14 t/t cane (dry basis). However, **Raízen identified the need to CARB staff also**
234.7 **implement this change in the Tier 1 CI Calculator.** As previously explained, this revised value is widely accepted by the academic community and is being utilized in numerous studies, including the latest versions of the Argonne GREET Model. **We therefore strongly ask CARB to reconsider this value in the Tier 1 CI Calculator.**

Figure 2. Current assumption for straw yield in the Tier 1 CI Calculator for sugarcane ethanol.

In conclusion, Raízen appreciates the opportunity to contribute with the LCFS rulemaking process and with CARB staff. Once again, we would like to put ourselves available for technical discussions with the high qualified CARB staff. We look forward to continuing the ongoing dialogue and collaboration staff to move forward with these discussions that we are certain will contribute to lowering emissions in the California transport sector.

Sincerely,

Raízen

Annex A. The Brazilian Electrical System

The Brazilian Electrical System (National Interconnected System - SIN) is 99% interlinked[4], so virtually all the production and transmission of electricity in Brazil happens in one main grid closely monitored by the National Electric System Operator (ONS), a federal agency responsible for coordinating and controlling operation of the electricity generation and transmission facilities in the SIN under the supervision and regulation of the National Electric Energy Agency (ANEEL). This unique system adopted by the country creates certainty as to what sources contribute to the marginal generation of power. Sugarcane biomass-based electricity in Brazil receives a fixed income to deliver a "package" of energy per year to the grid. Sugarcane biomass receives this fixed income for the energy it produces and declares its Unit Variable Cost (UVC) equal to zero, since cogeneration of sugarcane biomass electricity occurs in order to meet the demand of the sugar and ethanol industry. Wind and solar sources also have a UVC equal to zero. In this way, all the electrical energy these sources produce is made available to the national grid (since the government already paid a fixed income for it).

The procedure varies for thermo-gas sources. In addition to the fixed income they receive for standby readiness, their UVC exceeds zero. This implies that whenever the ONS deploys them, they are compensated for both their fuel expenses and operational costs. In fact, since sugarcane biomass is classified with a unit variable cost equal to zero, the ONS adopts the so-called merit order,where thermal plants from lower to higher operating costs are dispatched in order to meet demand. The ones with lower UVC are the first to be called to meet domestic demand. Since biomass plants have unit variable cost equal to zero, when available (during the sugarcane harvest season), they are the first to be dispatched to the system, without the need for an order from the ONS. Differently from sources like coal, diesel, and natural gas, the generation of energy from sugarcane biomass sources is controlled and dictated by the industrial process itself instead of by order of the national operator.

Board Comments Home

CRS

February 20, 2024

California Air Resources Board (CARB)
1001 I Street, Sacramento, CA 95814
Submitted Electronically

RE: CALIFORNIA AIR RESOURCES BOARD PUBLIC HEARING TO CONSIDER PROPOSED LOW CARBON FUEL STANDARD AMENDMENTS

Dear California Air Resources Board Staff,

Center for Resource Solutions (CRS) appreciates this opportunity to submit comments in response to the March 21, 2024 Public Hearing to Discuss Potential Changes to the Low Carbon Fuel Standard (LCFS) and Proposed Amendments to the Low Carbon Fuel Standard Regulation (hereafter "Draft"). We support the LCFS Program and the Assembly Bill (AB) 32 Scoping Plan. Our comments pertain to a utility-specific carbon intensity (CI) value of electricity, the definitions of environmental attributes and book-and-claim accounting, and book-and-claim accounting best practices for biomethane and hydrogen.

BACKGROUND ON CRS AND GREEN-E®

CRS is a 501(c)(3) nonprofit organization that creates policy and market solutions to advance sustainable energy and has been providing renewable energy and carbon policy analysis and technical assistance to policymakers and other stakeholders in California for over 20 years. CRS also administers the Green-e® programs. For over 20 years, the Green-e® program has been the leading independent certification for voluntary renewable electricity products in North America. In 2021, the Green-e® Energy program certified retail sales of over 110 million megawatt-hours (MWh), serving over 1.3 million retail purchasers of Green-e® certified renewable energy, including over 309,000 businesses.[1] The Green-e® Renewable Fuels program was launched in 2021, initially as a standard and certification for biomethane products and associated environmental attributes. This program is in the process of expanding to certify green hydrogen transactions and programs and can serve as a guide for CARB as it helps accelerate the adoption of biomethane and clean hydrogen, while ensuring that they are from sustainable renewable resources and meet the highest environmental standards, and that customers are protected in their purchase and ability to make verified usage claims.

COMMENTS ON THE DRAFT

Utility-Specific Carbon Intensity Value of Electricity

1. We recommend that the Lookup Table CI value for electricity be utility-specific CIs that represent retail electricity delivery.

235.1 The Lookup Table CI value for electricity should allow for entities to claim a utility-specific CI that reflects retail transactions instead of the California grid mix. This enables a more accurate reflection of the emissions associated with electricity use and is already part of the Oregon Clean Fuels Program.[2] To further improve the accuracy of this value, it should be updated to reflect electricity delivery to retail sales. The Lookup Table CI value for California grid electricity currently reflects the statewide grid average of electricity generation and does not reflect the sale of Renewable Energy Certificates (RECs) or voluntary electricity products. Since the LCFS allows for adjustments of CI scores based on contractual mechanisms like RECs and other contracts for specified power, the default CI should also reflect retail deliveries, not simply generation.

The California Energy Commission's (CECs) Power Source Disclosure (PSD) program would be the best place to start in determining this value. PSD calculates provider portfolio-specific emissions intensities that are intended to represent the emission intensity of electricity delivered to retail load. The PSD program requires that RECs must be owned and not sold.[3] The program also backs out voluntary renewable electricity product sales from provider's default emission intensity.[4] Using these emissions intensities could avoid double counting where voluntary green power programs and RECs are used to generate additional and incremental LCFS credits (i.e., the same renewable energy is included in the statewide grid average).

Environmental Attribute Definition

235.2 2. We recommend that CARB update the environmental attribute definition at § 95481 Definitions and Acronyms to: "*Environmental Attributes: Any and all impacts and benefits attributable to the generation from the Generating Unit, including but not limited to the fuel or resource type,*

[2] Oregon Clean Fuels Program Updated Electricity Carbon Intensity Values for 2021. Available at: https://www.oregon.gov/deq/ghgp/Documents/cfpUpdated2021CIs.pdf

[3] See Section 1393(c)(1)(B) of Power Source Disclosure Regulation in Title 20, CCR Available at: https://www.energy.ca.gov/programs-and-topics/programs/power-source-disclosure/power-source-disclosure-resources-retail

[4] See Section 1394.1 (a) of Power Source Disclosure Regulation in Title 20, CCR Available at: https://www.energy.ca.gov/programs-and-topics/programs/power-source-disclosure/power-source-disclosure-resources-retail

location, greenhouse gas emissions, greenhouse gas emissions avoided or displaced on the grid."

235.2 The definition in the Draft refers to all attributes as "emissions reductions,"[5] which is misleading as not all attributes of generation are reductions. For example, RECs reflect attributes of generation, including both the direct emissions and any avoided grid emissions associated with generation. But RECs are not carbon offsets and do not represent a quantity of emissions reductions.[6] We suggest using the above definition, which is consistent with the Western Renewable Energy Generation Information System (WREGIS)[7] and represents a more encompassing and accurate definition of environmental attributes.

<u>Book-and-claim Accounting Definition</u>

235.3

3. We recommend that CARB update the book-and-claim accounting definition at § 95481 Definitions and Acronyms to: "*Book-and-Claim Accounting is chain of custody model in which the administrative record flow is not necessarily connected to the physical flow of material or product throughout the supply chain. For example, the environmental attributes of low-CI electricity, biomethane or low-CI hydrogen may be separated from or matched with the use of grid electricity, fossil natural gas or hydrogen respectively.*"

The definition in the Draft describes book-and-claim accounting as "an indirect accounting system where a physical product and its environmental attributes can be separately traded."[8] The reference to "indirect accounting" may be misinterpreted as a reference to indirect emissions accounting. Indirect emissions, sometimes called avoided emissions, are the net changes in emissions on the grid due to the generation, while direct emissions are the emissions associated with the generation.[9] Since the emissions being tracked for LCFS are the direct emissions associated with electricity generation, this may be confusing. We recommend the above definition, which is based on the International Organization for Standardization (ISO)[10] 22095 Standard and reflects the broader use of the term in other sustainability accounting practices.

<u>Book-and-claim for Biomethane</u>

4. We recommend that CARB remove the requirement that eligible pipelines must flow towards California at least 50% of the time.

CRS supports the LCFS program rules that biomethane use may be demonstrated via book-and-claim accounting. But we are concerned by the requirement that eligible pipelines must flow towards California at least 50% of the time. We request more information regarding the overall the purpose or need for this restriction, the rationale behind the 50% number, and how it will be verified and how often.

235.4

The use of book-and-claim accounting, without the pipeline flow restriction, is an appropriate and successful use of book-and-claim accounting as it recognizes the realities of common carrier pipelines—in which fossil methane and biomethane are blended and indistinguishable—and values incentivizing biomethane production without undue restrictions regarding physical traceability. Limiting book-and-claim accounting based on the physical flow of pipelines is inconsistent with its premise and the contractual basis for credible claims of biomethane use from common carrier pipelines that CARB has established. The direction of physical flow on the pipeline does not affect the biomethane use claim of the entity holding the attestation of environmental attributes.

Please refer to CRS's December 14, 2022, comments to the California Energy Commission[11] for suggestions regarding additional requirements for verification of credible use claims for book-and-claim accounting for biomethane using both Renewable Fuels Certificates and the Green-e® Renewable Fuels program.

<u>Book-and-claim for Hydrogen</u>

5. CRS supports allowing the purchase and retirement of attributes and use of contracts to demonstrate use of renewable energy for hydrogen production from both electrolysis and steam methane reforming (SMR).

235.5

Book-and-claim accounting practices for both renewable electricity and renewable natural gas (i.e., biomethane) rely on energy attribute certificates[12] (e.g., RECs and Renewable Thermal Certificates, RTCs, respectively) to demonstrate clean energy use. The sections below describe the importance of energy

[11] Comments on the California Energy Commission Clean Hydrogen Program under AB209 (Docket 22-ERDD-03). Section: "Hydrogen Produced by Steam Methane Reforming" Pg. 3-4.
Available at: https://resource-solutions.org/document/121422/

[12] Delivery of energy attributes may also be verified in contracts and attestations which specify which party retains the right to make environmental claims on the attribute, and that no other party may make claims on the attributes. Using established certificates (e.g., RECs and RTCs) and tracking systems facilitates verification of attribute ownership.

attributes for clean hydrogen produced by electrolysis or SMR. Allowing hydrogen production facilities to purchase attributes and use contracts to demonstrate use of renewable energy for hydrogen production (book-and-claim) is essential to the feasible implementation of a clean hydrogen pathway. Requiring the retirement of these attributes or verifying their contractual delivery for use in renewable energy for hydrogen production avoids double counting. Relying on existing market mechanisms and established best practices facilitates the growth of clean hydrogen.

Hydrogen Produced by Electrolysis

235.5

CRS supports CARB's requirement that "any renewable energy certificates or other environmental attributes associated with the energy are not issued credits or claimed under any other voluntary or mandatory program."[13] Verifying the use of renewable electricity for the production of hydrogen requires RECs. RECs are defined very clearly in California by the California Public Utilities Commission (CPUC) as including "all renewable and environmental attributes."[14] As such, RECs are required to substantiate delivery and use of renewable electricity and the specified CI of a renewable generation unit. Whether renewable electricity is procured for hydrogen production using onsite generation, a power purchase agreement (PPA), or a utility program, for example, the associated RECs should be retired to substantiate exclusive use of renewable electricity at that hydrogen production facility and prevent double counting. RECs may be retired in WREGIS by or on behalf of hydrogen production for registered generators. In the case that the renewable generator used is not registered with WREGIS, RECs or generation attributes should be transferred and retired contractually on behalf of hydrogen production.

Hydrogen Produced by Steam methane reforming (SMR)

In the United States, 95% of hydrogen is produced by SMR, a reaction between a methane source, such as natural gas, and high-temperature steam[15]. Biomethane, also known as renewable natural gas (RNG), is increasingly recognized for its lower lifecycle greenhouse gas emissions and presents an opportunity to lower the carbon intensity of Hydrogen produced by SMR. CRS support CARB's requirement for hydrogen produced from biomethane that "the entity claiming the environmental attributes has the exclusive right to claim environmental attributes associated with the sale or use of the biogas or biomethane."[16]

There are multiple pathways for producing RNG, each with their own environmental and social considerations. Many of the same factors that are relevant to producing high quality renewable energy,

[13] Appendix A-1: Proposed Regulation Order (Proposed Sections for Amendments). 95488.8. (i)(1)(C)5
[14] See CAL. PUB. UTIL. CODE § 399.12(h)(2).
[15] For further discussion see U.S. IRS (2020). HYDROGEN STRATEGY Enabling A Low-Carbon Economy. Available at: https://www.energy.gov/sites/prod/files/2020/07/f76/USIRS_FE_Hydrogen_Strategy_July2020.pdf
[16] Appendix A-1: Proposed Regulation Order (Proposed Sections for Amendments). 95488.8. (i)(1)(E)1

such as accounting for fuel delivery, using sustainable resources, credit vintage requirements, and facility age have bearing on RNG production as well. The Green-e® Renewable Fuels program can serve as a guide for the eligibility rules for the LCFS to ensure that RNG used in hydrogen production meets the highest standards and has positive impacts.

Please refer to CRS's December 14, 2022 comments to the California Energy Commission[17] regarding the use of both Renewable Fuels Certificates and the Green-e® Renewable Fuels program for additional information related to fuels certificates, time-matching, facility age, vintage requirements, and impact considerations for hydrogen.

We thank you for this opportunity to provide comments on the LCFS Program. Please feel free to reach out with any questions or comments.

Sincerely,
Lucas Grimes
Manager, Policy

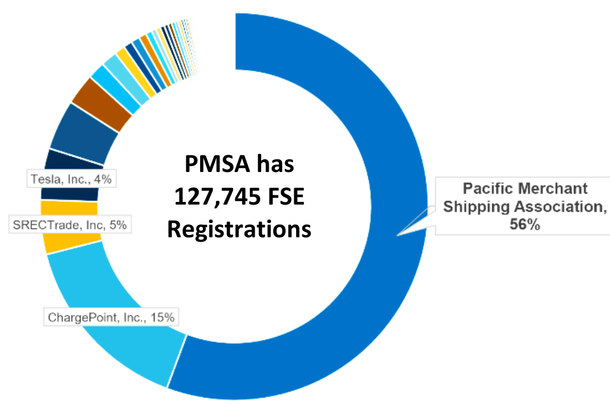
Comments Re: Proposed Low Carbon Fuel Standard Amendments (December 19, 2023)

On behalf of the members of the Pacific Merchant Shipping Association (PMSA), thank you for the opportunity to provide comments on the proposed Low Carbon Fuel Standard (LCFS) Program amendments. PMSA represents ocean carriers and marine terminal operators at California's public ports. In this capacity, PMSA also directly participates in the LCFS program on behalf of its member companies, facilitating the implementation of credit generation resulting in the broad and comprehensive participation by the maritime industry.

PMSA registers the largest number of Fuel Supplying Equipment (FSE) in the LCFS program statewide, with over 127,000 individual registrations today. As the largest program participant, PMSA submits these comments in support of the LCFS program overall, and to facilitate the successful continued participation by the maritime sector moving forward.



PMSA holds the most FSE registrations in California, at approximately 56%. As this graphic is based on Q1 2022 data, being the latest publicly available FSE registration data, PMSAs percentage has very likely grown due to continual eTRU registrations. PMSA may register 3,000 – 5,000 new FSEs *every quarter*.

236.1 As the single largest program FSE registerer, PMSA supports and welcomes raising the carbon intensity (CI)
targets and benchmark proposed, and we further support "auto-acceleration" to stabilize the credit market in
236.2 the event of rapid decarbonization. However, we are gravely concerned with the wholly unnecessary, wasteful,
and counter-productive proposed third-party verification for eCHE, eOGV, and eTRU transactions. These
unnecessary additions to the overhead cost of LCFS program participation will unduly impact the maritime
sector, reduce the monetary benefit of participation in the LCFS program and undermine the intent of the LCFS
236.3 program itself. PMSA does notsupport this proposal and urges CARB not to place new overhead and
administrative costs on its own successful program participants where no current program deficiencies have
been identified.

<u>Third-party Verification for eCHE, eOGV and eTRUs is Unnecessary and Diminishes Monetary Benefits</u>
PMSA strongly urges deletion of the additional proposed third-party verification requirements for eTRU, eCHE, and eOGV activities at items 2 through 4 of Section 95500(c)(1)(E). No clear and compelling justification exists for expanding third-party verification requirements to certain categories, including eCHE, eOGV, and eTRU, for Quarterly Fuel Transactions Reports (QFTR) (Section 95500(c)(1)(E)). To the contrary, the proposed expansion of third-party verification requirements will increase the costs of participating in the LCFS program, thereby diminishing the benefits of such a program, without meaningfully improving the quality of the data gathered. The eTRU, eCHE, and eOGV category third-party verification proposal specifically impacts the maritime sector, unjustly targeting the one sector that generates the single greatest source of credits, and which has an unblemished multi-year track record, as PMSA has complied and successfully participated in the program since its inception.

In most instances, PMSA utilizes reliable meter readings for equipment on dedicated circuits provided by the utility. In the few instances where utility meter data is not available, PMSA collects power consumption data directly from on-board telematic systems. All data collected over the course of the program is always available, and always has been available for CARB audit review upon request, at PMSA's expense. Third-party verification of these data sources upfront would not improve the existing high level of data quality or unparalleled availability of original data CARB staff on demand. As PMSA already utilizes the most accurate and reliable data
236.3 sources for reporting electrical usage available, *third-party verification is simply unnecessary for eCHE, eOGV, and eTRU transactions.*

Further, unlike eCHE and eOGV, eTRU equipment are not based at only one specific facility and must be individually registered for each usage every quarter. The LCFS regulation requires a new registration with a unique identifier based on the location. *PMSA can register 3,000 – 5,000 new FSE every quarter*. Due to this mobile nature and the immense quantity of eTRU activity and ongoing FSE registrations, third-party verification is not even possible for eTRU equipment, especially for third-party verification site visits.

As relayed previously, we are unaware of any specific data reliability or audit issues that exist with the current program. CARB staff have not identified any deficiencies which require changes to the program in order to be remedied. PMSA welcomes a discussion of those issues should they arise. In such an instance, we would expect CARB to facilitate a conversation about any existing concerns and how to effectively remedy those problems with our participating member companies and our consulting team and to specifically iron out those issues ahead of any significant programmatic changes. PMSA is also always ready to pro-actively organize a specific tour or demonstration at any time for CARB staff at a marine terminal in order to demonstrate the industry's reliable data collection methods should CARB staff find a theoretical weakness that should be explored, but which is currently unidentified.

As the single largest LCFS program FSE, the maritime industry remains transparent in its desire and eagerness to grow and expand its participation in the LCFS program. Unfortunately, the third-party verification proposal does nothing beyond only increasing the administrative burden and costs of participants. As far as we can ascertain, this proposal would only benefit the accredited verifiers who would be exercising the verification effort.

No real rationale is offered as justification in Appendix E ("Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements"). As no real deficiency is identified with respect to existing eTRU, eCHE, and eOGV activities, which are not currently subject to third-party verification, no justification is asserted for the claim that CARB must ensure "…electricity and hydrogen associated transaction types are held to the same standard of data quality through third-party verification." (Appendix E, page 117).

Electricity as a whole only accounted for approximately one quarter of the total 2022 annual credits. While it is claimed that "data assurance needs" for these sources cannot be met with the staffing capacity of CARB (Appendix E, page 117), as noted, there is no current program defect compelling third-party verification for all transaction types. Moreover, any additional burden estimated by CARB staff based on future potential data needs are counter-intuitive; in fact, if electricity and hydrogen transactions do continue to grow, the administrative burden would actually *decrease* for CARB. Any increased burden would only exist by CARB's own making: by amending Section 95500(c)(1) to include the fuel transaction types in question. And, as a result, both the state and regulated, participating community would find their administrative costs increased.

No Clear Estimate of Total Third-Party Verification Expenses for Aggregated Participants is Provided, Whilst the Outstanding New Liabilities Might Be Extraordinary

236.3 Given the lack of specifics, CARB cannot reliably calculate the total cost and expense of third-party verification, but all parties acknowledge that it is certainly significant. Even though it is currently impossible to calculate third-party verification service expenses because of the many questions which remain as to what CARB would actually require for electrical transactional verifications, the costs to an FSE aggregator such as PMSA could be staggeringly high relative to the value of the credits generated.

As PMSA works on behalf of its member companies to administer and aggregate credit generation at multiple facilities and locations in California, these many unknown variations in site visits could significantly alter expenses incurred. For example, is a physical site visit to every location where a charger is installed to be required? Or, is a site visit to the company or administrator headquarters sufficient? Given the number of participating PMSA members and locations, the total cost per annual visit has been estimated at $100,000 - $150,000, not including plan preparation, review and other administration services required for verification. A $150,000 expense per year and/or per visit, is not insignificant and may render the LCFS program impractical for PMSA or specific members, undermining the LCFS program's effectiveness. These funds, which would otherwise be utilized for expanding electrical capacity and purchasing zero-emissions equipment and infrastructure, would now either be eaten up as overhead costs, or result in foregone participation altogether. In practical terms, this $150,000 could instead fund approximately six heavy-duty eCHE chargers at the ports, directly championing the state's, port's, and maritime industry's goal of 100% zero-emission cargo handling operations.

236.3 Eligibility for less intensive verifications for the electrical transactions in question is proposed per Section 95500(h); however, questions remain on what the "less intensive verification services" entail for the following two annual verifications. If site visits are still to be required, the expenses would not be reduced, regardless of "intensity." While in some instances it might be reasonable to require one initial site visit to the company or administrator headquarters for the first annual electrical transaction verification, even in such a scenario no subsequent site visits should be necessary. FSE data will remain always available as needed, based on operations and the data collection mechanism utilized. Site visits should not be required for any data collected via the utility meter or directly from on-board telematic systems.

Electrical Transaction Third-party Verifications Would be Challenging Timing Wise and May Result in a Barrier to Credit Generation Altogether

236.3 PMSA also has concerns regarding the timing and the frequency of reviews, as they may restrict access to credit generation. In many instances, utility data is made available with very limited time remaining prior to required submittal timelines to CARB. If third-party additional reviews are to be required, there may very well be insufficient time for a third-party to complete their review and verification to meet the deadlines for LCFS credit generation in a specific quarter. Third-party verification for eCHE, eOGV, and eTRU transactions may cause Annual and Fuel Transaction Reporting delays, thereby threatening credit generation and associated proceeds, further undermining the intent of the LCFS program.

While we understand the CARB intends these changes to increase accountability and transparency in these transactions, they must be balanced against the overall health and effectiveness of the LCFS credit market. The participants in the current program have demonstrated exceptional transparency and high participation rates, even during periods of very low prices for credit generation. These changes which threaten that stability, high levels of participation, and access to the credit market should be studiously avoided.

We appreciate the opportunity to provide comments regarding the LCFS amendments. PMSA strongly urges CARB to reject the proposed third-party verification requirements for eTRU, eCHE, and eOGV transactions. We welcome facilitating an ongoing conversation on how to effectively remedy any perceived issues as it relates to electric equipment activity by our members. Please feel free to reach out to us by email (jmmoore@pmsaship.com) should you have any questions.

Sincerely,

Jacqueline M. Moore

Submitted Electronically

Subject: Los Angeles Department of Water and Power's Comments on California Air Resources Board's Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Chair Randolph and Honorable Board Members,

The Los Angeles Department of Water and Power (LADWP) appreciates the opportunity to provide comments on the California Air Resources Board's (CARB) Proposed amendments to the Low Carbon Fuel Standard (LCFS) Regulation (Proposal) posted on December 19, 2023, and updated on January 1, 2024. LADWP reaffirms its strong support of the LCFS program and its role in achieving the substantial greenhouse gas (GHG) emissions reductions goals of AB 32, SB 32, and AB 1279.

As an electrical distribution utility (EDU), LADWP is the largest municipal electric utility in the nation, serving approximately 1.4 million residential and business customers. As a large publicly owned utility, LADWP is in the most optimal position to promote transportation electrification and reduce financial impacts to our customers by investing in programs that benefit everyone. LADWP offers the following comments on the proposed amendments for your consideration.

I. <u>§ 95484. Annual Carbon Intensity Benchmarks and Automatic Acceleration Mechanism</u>

The LCFS regulation is vital to decarbonizing the transportation fuel sector. LADWP supports CARB's proposed 30% reduction in fuel carbon intensity (CI) by 2030 and 90% reduction in fuel CI by 2045. To comply with long-term zero-emission vehicle adoption targets of regulations such as Advanced Clean Cars II, Advanced Clean Fleets, Advanced Clean Trucks, and others, which have deadlines in 2045, extending the LCFS program will continue providing essential support for the transition. LADWP agrees with CARB staff that long-term deployment of low carbon technologies is necessary to achieve long-term transportation decarbonization goals.

237.1 Additionally, LADWP supports the proposed near-term step-down and Automatic
Acceleration Mechanism. LADWP agrees that there needs to be a mechanism in place
237.2 to enhance the stringency of the standard if and when transportation decarbonization
advances more rapidly than staff initially anticipated.

II. § 95483(c)(1). Updates to Residential EV Charging

a. *Base Credits*

LADWP has been a long-time advocate of electrifying the transportation sector. From
light-duty electric vehicle charger rebates first offered in 2013 to medium- and heavy-
duty vehicle charger rebates in 2018 and previously owned electric vehicle rebates
expanded in 2023, LADWP continues to develop various programs that promote electric
vehicles and increase benefits to disadvantaged communities and low-income
customers. LADWP relies on the LCFS program to continue funding these equity-
focused efforts while reducing the financial impacts to our customers. LADWP supports
237.3 the proposed reduction in the Publicly Owned Utilities' (POUs') minimum base credit
contribution required to fund the Clean Fuel Reward and the corresponding increase in
237.4 the holdback credit which will help fund LADWP's transportation electrification
programs.

b. *Restrictions on Use of Holdback Credits*

LADWP supports the Proposal to keep the holdback equity requirement for POUs at
237.4 50% as stated in Appendix E (page 15) of the Proposed Amendment. However, this is
not reflected in the language of the proposed regulation in section 95483(c)(1)(A)5.a.
LADWP recommends that CARB staff amend the language of the proposed regulation
to explicitly state the holdback equity requirements for POUs for clarification.

LADWP also agrees that the projects listed under section 95483(c)(1)(A)5.a. (Holdback
Credit Equity Projects) unconditionally support the equity community and applaud
237.5 CARB's efforts to include them. Under this section, a list of preapproved projects follow
the statement, "These projects may include:", which casts uncertainty on whether all
listed projects qualify as supporting equity. LADWP asks that CARB amend the text to
clarify CARB's intent that the list of preapproved projects unconditionally supports equity
(i.e. regardless of location of the project).

Section 95483(c)(1)(A)5.b. (Other Holdback Projects) of the Proposed Amendment
states that, "Holdback projects that are not specified in subsection 95483(c)(1)(A)6.a.
237.5 must follow the requirements…". LADWP asks CARB to verify whether subsection
95483(c)(1)(A)6.a. was incorrectly cited and instead was intended to refer to
95483(c)(1)(A)5.a.

Depending on which activities qualify towards the definition of administrative cost, the
proposed reduction in allowable administrative costs for holdback credit equity projects

237.6 to 5 percent of total spending on holdback credit equity projects may be too low, as proposed in section 95483(c)(1)(A)5.c. There is a misalignment on what is considered administrative cost between CARB's programs (i.e. LCFS guidance and Cap-and-Trade guidance), and other regulators (i.e. CPUC's Energy Efficiency Policy Manual). LADWP recommends that CARB staff clearly define and list examples of activities that are considered administrative and consider keeping the allowable administrative cost at 10 percent for holdback credit equity projects.

III. § 95483(c)(2), 95491(d)(3)(A), and 95491(e)(5) Uses of Electricity Credit Proceeds for Non-Residential Electrical Vehicle Charging

The reclassification of non-limited chargers located at multi-family residences as non-residential EV charging, and subsequent changes to sections 95483(c)(2)(C), 95491(d)(3)(A), and 95491(e)(5), raise questions on the requirements for non-Load Serving Entity (non-LSE) owners of EV chargers at multi-family residences. In the Proposed Amendment, section 95483(c)(2)(C) includes a revision that replaces the requirements set forth in paragraphs 2. through 7. in section 95491(d)(3)(A) with requirements in section 95491(e)(5). The original language in paragraph 7 of section 95491(d)(3)(A), which is copied below, clearly cites the specific requirements for non-LSE owners making it clear how the cost of charging is applied:

> "A non-LSE credit generator must use credit proceeds to benefit EV drivers and their customers and educate them about the benefits of EV transportation (including environmental benefits and costs of EV charging, or total cost of ownership, as compared to gasoline). The credit generator must include, in their Annual Compliance Report, an itemized summary of efforts and costs associated with meeting these requirements."

The new proposed language under Section 95491(e)(5), as cited below, on the other hand, is more general and lacks the pertinent information that the previous language specified:

> "Entities generating credits from electricity must use all credit proceeds to further transportation electrification efforts in California. The credit generator must include, in their Annual Compliance Report, an itemized summary of efforts and costs associated with meeting this requirement."

237.7 LADWP is concerned with the new language's shift of allowable use of credit proceeds from benefitting EV drivers and customers to a more general "further transportation electrification efforts." From LADWP's experience, even with the current customer-focused requirements, credit proceeds are not being passed down to customers via affordable rates or incentives at multi-family residences. After charger installation, single-family residents pay little more than the cost of electricity to fuel their EVs. By contrast, multifamily residents can be subjected to additional fees, benefiting operators or landlords, eliminating the driver's cost savings versus fueling with gasoline. The cost of charging may be a barrier for EV adoption for residents of multifamily buildings. LADWP recommends that CARB consider amending the proposed language to include provisions to protect the customers, such as requiring non-LSE credit generators with

237.7 EV chargers located next to a multi-family residence to provide affordable rate options to those multifamily residents.

IV. § 95486.2(b) and 95486.3(b). Generating and Calculating Credits for ZEV Fueling Infrastructure Pathways

237.8 LADWP supports the proposed amendments that expand the current ZEV infrastructure crediting provisions beyond light-duty (LD) infrastructure to medium- and heavy-duty (MHD) infrastructure and extending the light-duty crediting. LADWP believes that infrastructure crediting will help reduce the risk of under-utilized chargers and will drive the buildout of necessary infrastructure.

V. § 95501. Requirements for Validation and Verification Services

Staff's proposal to add third-party verification requirements for EV charging except for section 95491(d)(3)(A) (non-metered residential) means that metered residential transactions, for base credits or incremental credits, will be subject to verification. Verification of residential EV charging may be challenging because of the required site visits.

Section 95501(b)(3) states that, "*Site Visits*. At least one lead LCFS verifier accredited by the Executive Officer on the verification team must, in addition to one visit to validate an application, annually visit each facility; and, if different from the fuel production facility, the central records location for which the records supporting an application or report subject to verification are submitted."

237.9 Annual site visits to *each* facility for verification of Quarterly Fuel Transactions Reports can be time consuming and burdensome. Fuel transactions that are low risk can easily be verified using the Lookup Table CIs, site visits, especially for the verification of residential EV charging data. LADWP recommends that CARB staff amend or add language that allows for site visits at a central records location for these types of verifications or exempt these transactions from the site visit requirement. Additionally, for small credit generators, it may not be financially feasible (even with deferred verification) to hire third-party verifiers. LADWP recommends verification exemption, through the Executive Officer approval process, for when the cost of verification exceeds the value of the LCFS credits generated.

In closing, LADWP appreciates the opportunity to provide comments and feedback on these important topics. If you have any questions about LADWP's comments, please contact Ms. Andrea Villarin at (213) 367-0409 or Mr. Bang Phung at (213) 367-8689.

Sincerely,

Katherine Rubin

Board Comments Home

February 20th, 2024

To the California Air Resources Board:

Thank you for your innovation and dedication to making California the standard by which all other environmental policy is judged. As a developer of electric vehicle charging infrastructure and member of CalETC, Carbon Solutions Group strongly supports California's LCFS program. We consider this program to be the main lever in statewide EV adoption, as well as the model for so many emerging fuel standards across the country.

Today, CARB's progressive policies remain as crucial as ever for driving zero emissions economic development. Notably, EV sales have recently seen a significant, and surprising, slowdown. Various other recent indicators of industry trouble include Hertz announcing that it will jettison 20,000 EVs from its fleet (to which the market responded favorably) as well as media commentators warning of consumer "range anxiety" cooling interest in pure EVs. Over the last several years, low utilization rates and macro-economic factors have also resulted in EV industry burnouts and below market acquisitions by oil and gas majors.

Thus, this next round of LCFS amendments may be decisive when it comes to pushing EV adoption into the mainstream. This is especially the case regarding LD EV adoption amongst historically disenfranchised communities, which maintain the lowest utilization rates and the least financial incentive to abandon gasoline. Presently, as CARB no doubt already knows, LD EVs appear to be most utilized in higher-income homes, and often as secondary vehicles. And while we agree with CARB that EV sales will increase in the years to come, we are not confident that an increase in vehicles will, *de facto*, be evenly distributed across income types, nor that EV sales will necessarily increase linearly with throughput. EV sales and EVSE development remain on two separate, but linked, trajectories.

For the disenfranchised, several fundamental obstacles are presently at play. DCFC economics in low-income/low utilization areas often result in a high price-per-kWh of throughput, which can end up with a "pump price" greater than gasoline. This high price-per-kWh is caused by the low utilization (thus expenses are spread across fewer kWhs) as well as the fact that wear-and-tear costs are more prevalent in public charging stations (as opposed to MHDV stations which are frequented by professionally trained drivers). Perhaps most important, access to home charging is a critical factor when prospective combustion engine drivers consider EV adoption. It appears that most low-income drivers do not currently have access to L2 home charging.

In short, to reach an inflection point in which EVs become the primary mode of transport in California, we believe EVs will need to become the primary mode of transport for middle- and low-income drivers. While EV adoption amongst the upper classes has been largely ideological in nature, EV adoption amongst those struggling paycheck-to-paycheck needs to be a purely economic decision. That decision will be based on whether sound EVSE businesses can offer price competitive charging optionality. Thus, California's stated climate goals will continue to require policy-driven economics that aggressively incentivize the installation and operation of charging infrastructure.

To that end, we are supporters of CalETC's recommendations for the present round of proposed LCFS amendments, in both LDV and MHDV categories. In addition to the group's formal recommendations, we also propose the following items for your consideration. In some cases (e.g., base credit qualification), we offer an appeal outside the scope of CalETC's position. In other cases (e.g., deficit cap and geographic restrictions), we echo CalETC's formal recommendations.

Residential: Base Credit Qualification

As per Section 95483(c)(1)(A), EDUs presently retain base credits for metered and non-metered residential charging infrastructure. We see this statute potentially undermining the larger goal of majority EV adoption.

From an economic perspective, the inability for an EVSE owner to claim a base credit eliminates a key incentive for that owner to implement charging infrastructure. Considering single-family homeownership has become cost-prohibitive for many Californians, multi-unit dwellings and rentals are particularly important. By awarding residential EVSE owners with base credits + incremental credits (whether single-family or multi-unit), we believe middle- and low-income EV adoption will significantly increase.

While we recognize that EDUs do in fact use base credit earnings to distribute zero emission rebates to disadvantaged/low-income communities, we believe that this indirect allocation does not efficiently incentivize the primary risk takers in California's LCFS—the producers of low-carbon fuel solutions. Directly incentivizing these builds is paramount when it comes to establishing a landscape in which low-income EV adoption is possible. In other words, if the charging infrastructure is not readily available, indirect rebates to drivers/homeowners may be irrelevant.

Additionally, by providing the option for aggregators to also participate in base + incremental credits (along with the EVSE owners), CARB could establish an incentive to create an efficient framework that limits the potential for individual account creation overload, while still rewarding individual residential accounts.

238.1 At minimum, awarding base + incremental credits to EVSE owners for L2 communal parking in multi-unit dwellings would make the most substantial impact in any single property category, as a communal charging option in multi-unit/rental residences can open up the opportunity for low-to-middle income drivers to adopt EVs with greater ease. Growth in communal L2 charging in multi-unit dwellings can also help support CARB's broader goal of achieving a greater volume of distributed charging points rather than fewer, congested charging points.

238.1 Yet, from the regulator's perspective, it is important to drive advances in innovative, clean infrastructure and not to merely spur adoption of existing supply chains. To that end, another element that could further justify awarding EVSE/network owners with base + incremental credits could be that the award is premised on the installation of bi-directional chargers for multi-unit and/or single-family residences. Bi-directionality is a value-add that would further both grid resilience and California's climate goals.

Residential: Metered Base Credit Qualification

As is known, in metered residential scenarios, EDUs have no access to specific charge point metering, unless the EDU operates the charge point itself or the charge point is on its own sub-meter. Therefore, EDU-qualified non-metered base credits are necessarily premised on assumptions. Because these factors are based on averages, rather than actual utilization (which can vary widely), these base credits do not rely on the best available data that accurately reflects real world utilization dynamics.

On the other hand, designated aggregators, EVSE owners, and telematics-enabled vehicle owners have access to real utilization data specific to each charge point/vehicle. This data is exact and not based on averages.

238.2 We respectfully appeal to CARB to consider awarding base + incremental credits to qualified EVSE owners/aggregators that are able to report actual, metered utilization data. This base + incremental credit qualification would prioritize best available data whenever it is available. In turn, this would likely lead to more stringent credit generation, as the metered credits would be based on *actual* utilization rather than *estimated* utilization. In this way, the aggregator/EVSE owner can be rewarded for providing CARB with the best available data.

Public-Private: Verification Requirements

238.3 By allowing designated aggregators and EVSE owners to participate in base + incremental credits, the verification process can also be optimized at a lower cost and faster speed.

CARB's proposed verification requirements (i.e., that site hosts must pay for 3rd party in-person verification) will incur significant costs and operational friction that fall outside of current industry models, in turn, severely damaging overall industry momentum. However, we believe that, by providing CARB with real utilization data, designated aggregators and EVSE owners can easily enable a purely desktop verification methodology that will 1) achieve equitable if not greater integrity at a lower economic cost than in-person site visits; and 2) efficiently eliminate potential redundancies in the process.

Regardless of the above, we also respectfully suggest a change regarding the proposed verification deferment option for entities generating less than 6,000 credits/year. Instead, we recommend that entities that generate less than 2,001 credits/year be exempted from all verification, and that those applicants with 2,001 to 6,000 credits/year be eligible for deferment of 3rd party in-person verification.

238.4 Likewise, we respectfully ask CARB to further clarify that only credits subject to verification count towards the credit cap for deferment or exemption. Overall, we believe

238.4 cont deferment and exemption can potentially have a sizable impact in incentivizing residences to come online with charging infrastructure.

Public-Private: DCFC for Multi-Unit Dwellings

Certain L2 installations for multi-unit dwellings face logistical challenges, particularly for retrofits of existing properties. In some cases, common parking spaces are limited, leading to an undersupply of L2 charging points within the dwelling's parking lot (if such a lot even exists). In other cases, structural complexities may pose too great an obstacle for L2 installation on site.

238.5

In addition to allowing EVSE owners to retain both the base + incremental credits, one remedy to this challenge would be to incentivize DCFC infrastructure on-site, adjacent, or proximally located within five miles of a multi-unit dwelling. Proximal fast charging can compensate for cases where there is an insufficient number of L2 chargers, and still address an underserved population that is central to the broader goals of the EV industry and the State of California. FCI credits allotted to multi-unit-based/adjacent DCFC, even if not publicly accessible to non-tenants, could provide the proper incentive in this regard.

Public: FCI Parity with Hydrogen (HRI)

238.6 We believe there is a lack of equity between the proposed LD FCI program and the LD HRI program. Specifically, we strongly appeal to CARB to reconsider the allowance of REC matching to achieve 0 CI electricity in the FCI formula. Doing so, would create equal conditions for FCI and HRI, as currently only H_2 can claim 0 CI as per the proposed regulation.

Carbon Intensity Step-Down

238.7 We believe that an immediate CI step-down of at least 7% (instead of 5%) would help push the market to more significant levels of emissions reduction. Again, we believe that the next few years are a time in which to push forward ever more aggressively in meeting California's climate goals.

Public: LDV FCI—Deficit Cap

Considering the precarious economic landscape laid out above, we recommend that CARB retain the 2026-2030 deficit cap at today's 2.5% (rather than the proposed 0.5%).

238.8

To reach California's goals, as set out by ACC II, more than an 8x increase in DCFC will be required, as today's ~10,000 DCFC must reach 83,000 in the next eleven years. Likewise, ACC II calls for a dramatic increase in EV sales—with today's 20% market share needing to reach 100% in the next eleven years. However, even if this ambitious increase in EV sales is achieved, a correlating increase in DCFC is unlikely to be supported by market-driven consumer demand alone for some of the reasons laid out previously in this letter. And, conversely, if extensive charging infrastructure does not materialize, an exponential growth in EV sales may be hard to manifest on its own. Therefore, policy-driven DCFC economics will remain a necessity to reach ACC II objectives. Without strong policy-based incentives, low utilization areas (e.g., low-income, rural, etc.) will suffer the worst from a lack of DCFC infrastructure.

238.8 cont Within this context then, we do not believe a 0.5% cap will sufficiently incentivize DCFC to ACC II levels. Instead, a 0.5% cap would likely spur a major slowdown in DCFC development.

Public: LDV FCI—Geographic Restrictions

238.9 For similar reasons laid out above (re: maintaining a 2.5% cap), we also contend that geographic restrictions on public FCI would likely impinge on greater EV adoption, particularly among the low-income and middle-income communities that are the most important to incentivize. Geographic restrictions will likely cause investor confusion and conservatism (whether deserved or not) at a time when more capital needs to be deployed for infrastructure in low utilization locales.

In both cases (re: 2.5% and no geographic constraints), we do not project an oversupply of credits due to the self-limiting nature of FCI—in that as kWh consumption increases, the FCI credits decrease. More so, CARB's novel acceleration mechanism should successfully buffer against significant credit devaluation.

Public: FCI Timing for LDV

238.10 As per the amendment of Subsection 95486.2(b)(4)(H): While we fully support this helpful capex multiple, we respectfully appeal to you, to qualify it for immediate application upon passage of the regulation (ca. 2024), as opposed to its stated 2026 start date. As noted above, a variety of pressing economic challenges currently face public charging infrastructure. The ability to utilize this amendment sooner than 2026 would be most efficacious in bridging and rapidly scaling up LD charging infrastructure, particularly in those low-income areas that could most benefit.

We appreciate the time and attention you have given to considering the details of this letter. We commend you on your leadership and look forward to implementing another phase of a world-changing program.

Best Regards,

Michael Daley

Comment

```
Hello,

I'm submitting a letter from environmental justice, environmental,
public health, and labor groups requesting that CARB remove direct
air capture and enhanced oil recovery using captured carbon from
the Low Carbon Fuel Standard.

Please feel free to reach out with any questions.

Wishing you well,

Dan Ress

Submitted via CARB's online Comment Submittal Form

Re: Opposition to the Proposed LCFS Provision to Allow Direct Air Capture Crediting Nationwide and to the Continued Crediting of Enhanced Oil Recovery Using Captured Carbon

Dear Chair Randolph and members of the CARB Board,

The undersigned groups write to express their strong opposition to the California Air Resources
239.1 Board (CARB) staff proposal regarding the Low Carbon Fuel Standard (LCFS), specifically provisions
regarding nationwide direct air capture (DAC) crediting and carbon capture and storage (CCS) crediting
239.2 for projects that use captured carbon for enhanced oil recovery (EOR). These two programs risk
undermining any climate benefits from the LCFS while exacerbating environmental injustice. As such, we
urge CARB to revise the staff proposal to eliminate crediting for DAC and EOR using captured carbon.

DAC does not belong in the LCFS because it is not a transportation fuel.

The LCFS is a market mechanism intended to reduce the carbon intensity of California's transportation fuels. DAC is a new, speculative technology—so far never deployed at scale—that aims to reduce atmospheric carbon dioxide (CO2) by capturing it from the ambient air. The main product of DAC is CO2, a waste product from excessive combustion that must be buried deep underground.[1] While there are proposals to use CO2 to create new transportation fuels, in almost all cases CO2 from DAC will not be

239.1 cont used to create fuels, let alone transportation fuels in California. Since it has no apparent relationship to California's transportation fuels, DAC does not belong in a program intended to address the carbon intensity of California's transportation fuels, and it should be omitted from the LCFS.

Including DAC in the LCFS would delay necessary direct emissions reductions and the phase out of fossil fuels.

The combustion of fossil fuels is the primary driver of the climate crisis, and the scientific consensus is that they must be phased out quickly to prevent global catastrophe and the collapse of human civilization. At the same time, the combustion of fossil fuels causes severe air pollution across the world, the nation, and the state, including in the San Joaquin Valley, the nation's worst air basin. Moreover, that air pollution burden is not just concentrated geographically but also socioeconomically and racially such that low-income communities of color are much more likely to live with far worse air pollution. As such, both public health and environmental justice require the swift phaseout of fossil fuels.

Over-reliance on CDR would present the grave moral hazard of delaying direct emissions reductions and the phaseout of fossil fuels. If we delay this needed action, we risk exacerbating the environmental justice, public health, and climate crises, and ultimately the collapse of our civilization.

239.1 cont Because the LCFS is a market mechanism that relies on tradable credits, any projects that generate credits allow the continuation and development of projects that need to purchase credits, such as fossil oil and gas refining. DAC crediting will thus directly facilitate the combustion of fossil fuels that would otherwise not be burned (or would need to be offset by other low-carbon-intensity fuels in California's market). The net impact is to decrease our ambition to reduce combustion of fossil fuels.

DAC must be reserved for truly hard-to-decarbonize sectors because it is so energy intensive and expensive.

The transportation sector can be decarbonized without relying on offsets from CDR such as DAC. CARB's own Advanced Clean Cars and Advanced Clean Fleets rules and accompanying analyses show that ambitious transition to zero emission vehicles (ZEVs) is possible in this sector. While transoceanic shipping and aviation are more difficult to decarbonize, those subsectors, too, include realistic decarbonization pathways in the relevant time frame.

[1] Captured CO2 can also be used. The only use for CO2 proven at scale is for EOR, discussed further below.

Because carbon is just 0.0421% of the atmosphere, capturing it from the ambient air is exceptionally expensive and energy intensive.[2] Considering the challenges of quickly deploying renewable energy with storage and transmission as we electrify our economy, we should be cautious about embarking on projects that require gross expansion of renewable energy capacity to power them. In the face of this reality, insofar as the state decides to include DAC in its climate plans, we must reserve DAC to offset emissions from truly hard-to-decarbonize sectors.

239.1 cont DAC, insofar as the state relies on it despite its cost, energy burden, and lack of proven track record at scale, must not be used to offset transportation emissions—where other solutions exist—but instead must be reserved for other sectors without viable decarbonization options.

DAC only makes sense if it is carbon negative, yet crediting DAC in the LCFS ensures that it can be carbon neutral at best.

Given the moral hazard and extreme expense and energy burden of DAC, it only makes sense to employ DAC when it is carbon negative. However, when a DAC project generates LCFS credits, those credits will be acquired by fossil oil refiners, offsetting any possible reduction in atmospheric carbon and at best resulting in the DAC project being carbon neutral. DAC projects that are not carbon negative offer no benefit, but rather waste precious climate funding on fossil fuel greenwashing.

The staff proposal allows double- and triple-counting DAC credits, potentially resulting in significant increases in carbon emissions.

In other provisions of the proposed LCFS amendments (e.g., book-and-claim electricity, book-and-claim RNG, book-and-claim hydrogen, renewable or low-CI process energy), the regulation text prohibits generating LCFS credits if the Renewable Energy Certificates (RECs) or environmental attributes are "being claimed in any other voluntary or mandatory program" with certain exceptions. Conspicuously absent from this provision are both DAC and CCS projects.[3] As such, DAC projects credited under the LCFS are likely to generate credits in multiple programs, and thus to offset carbon emissions in multiple markets. Anywhere DAC generates credits, it allows further emissions, so where credits are stacked, it effectively allows double or even triple counting. In other words, under the staff proposal, credited DAC projects could effectively cause emissions to increase by a factor of two or three relative to a scenario in which DAC does not occur—an outcome that would be simply unacceptable.

And that analysis only considers literal crediting programs, leaving out other incentive programs. If a project collects a grant from the U.S. Department of Energy, for example, the federal government will likely claim its negative carbon emissions in its own accounting while the project also generates offsets in the LCFS and other markets, allowing further over-counting. The above also leaves out opportunity costs, such as of the foregone transition from fossil fuels to renewables, with the renewable capacity that could

---

[2] See, e.g., Sekera, J., Lichtenberger, A., Biophys Econ Sust., *Assessing Carbon Capture: Public Policy, Science, and Societal Need* (Oct. 2020), https://doi.org/10.1007/s41247-020-00080-5.
[3] E.g., Section 95488.8(i)(1)(B)(3).

have been used for the transition instead going to DAC. The implications from employing such flawed accounting in our climate programs is very alarming.

To be effective and safe, nationwide DAC projects need better oversight than CARB can provide through the LCFS.

Outside of California, CARB has a limited presence and jurisdiction. While CARB can certainly review documents from out of state, it is unlikely to conduct frequent onsite inspections for DAC projects in, say, Louisiana, but rather will count on oil majors to honestly conduct their operations, despite the well-documented history of oil companies lying for decades about climate science.[4] Without careful oversight, projects likely will not provide any climate benefits at all and may instead cause net increases of greenhouse gases. Further, poor oversight and weak regulations in other states may result in significant local harms.[5]

DAC's extreme energy demands can be met by any energy source, but CARB must ensure that, where it allows or incentivizes deployment, DAC only employs clean renewable energy with storage. However, some DAC projects plan to use fossil fuels for energy, such as one of the Carbon TerraVault projects that intends to use methane fuel cells , which will paradoxically yield greenhouse gas emissions while trying to capture CO2. Meeting DAC power demands with fossil fuels, whether onsite or through the grid, could cause projects to generate more greenhouse gases than they capture. In addition, they will cause local harms along the lifecycle of those fossil fuels, from extraction to refining to transportation to storage to combustion.

239.1 cont

Insofar as DAC projects plan to rely on the electrical grid as a primary or secondary energy source, the projects will only be clean if the grid is clean, which will not be the case until it is fully supplied by renewables with storage. Further, renewable supply consumed by DAC is renewable supply that cannot meet other energy demands, so the proper baseline for assessment is against the grid with the same capacity but without DAC.

Given the impossible task of ensuring broad compliance with such tight parameters nationwide, CARB staff cannot responsibly manage such a program and call it CDR. As such, CARB must remove nationwide DAC crediting from the LCFS.

DAC must be deployed sparingly because of local harms.

---

[4] See, e.g., Louis Sahagún, Los Angeles Times, California sues five major oil companies for 'decades-long campaign of deception' about climate change (Sept. 2023), https://www.latimes.com/california/story/2023-09-16/california-sues-five-major-oil-companies-for-lying-about-climate-change.

[5] California also lacks strong community protections for DAC and CCS. We look forward to the SB 905 rulemaking to produce strong protections for our communities soon, before these projects beat regulators to the punch.

Apart from the climate harms discussed above, and even assuming that DAC relies exclusively on onsite, behind-the-meter renewables rather than fossil fuels, DAC is dangerous and must be carefully regulated and limited in deployment.

239.1 cont Most DAC projects rely on toxic materials like ammonia to filter carbon from ambient air, and thus they risk leaking toxic pollution into the air and water.[6] Moreover, DAC's intended purpose is to gather and concentrate CO2, which is a toxic waste.[7] An accident at a DAC facility would present grave risks for workers and surrounding communities for miles around. DAC can be done anywhere, so it is feasible to construct DAC facilities away from communities and right above storage formations to avoid the need for carbon pipelines, but unfortunately, California, along with most other states, does not have a requirement that DAC only occur well away from where people live.

Storing carbon is also a significant concern. Underground geologic storage is not well studied for climate purposes.[8] Perhaps the best studied projects are Norway's Sleipner and Snøhvit projects, often held up by industry as shining examples of the promise of CCUS technology. However, as the Institute for Energy Economics and Financial Analysis found in a 2023 report, these projects are better understood as cautionary tales, demonstrating that "carbon capture and storage is not without material ongoing risks that may ultimately negate some or all the benefits it seeks to create"; that "[e]very project site has unique geology, so field operators must expect the unexpected, make detailed plans, update the plans and prepare for contingencies"; and that "[e]nsuring storage is securely maintained implies a high level of proactive regulatory oversight, activities for which governments may not be adequately equipped". The report also finds that the facilities "cast doubt on whether the world has the technical prowess, strength of regulatory oversight, and unwavering multi-decade commitment of capital and resources needed to keep carbon dioxide sequestered below the sea – as the Earth needs – permanently."[9]

Leakage pathways for geologically stored carbon include the ~100,000 oil and gas wells just in Kern County, California's many tectonic faults, and other natural and manmade perforations or cracks in storage formations. Also, upon interacting with water, CO2 forms carbonic acid. While carbonic acid is safe to drink, it harms irrigation supplies. In California, that could have serious implications because our storage formations are right below the nation's most productive agricultural lands in the Central Valley.

B. et al., *The application of amine-based materials for carbon capture and utilisation: an overarching view*, in Material Advances, 2021, 2 5843-5880; EEA Technical report no. 14/2011, *Air pollution impacts from carbon capture and storage (CCS)*, (2011), https://www.eea.europa.eu/publications/carbon-capture-and-storage, at p. 10; Report of the Special Rapporteur, Okechukwu Ibeanu, *Adverse effects of the illicit movement and dumping of toxic and dangerous products and wastes on the enjoyment of human rights*, report no. A/HRC/5/5 (2007), https://undocs.org/Home/Mobile?FinalSymbol=A%2FHRC%2F5%2F5&Language=E&DeviceType=Desktop&LangRequested=False at p. 8.

[7] When concentrated, CO2 is indeed toxic, and, because it is a waste product from combustion and most plans involve burying it deep underground to keep it out of the atmosphere, toxic waste is an apt description.

[8] The oil and gas industry has studied EOR using captured carbon extensively, but as a climate tool geological carbon storage remains in its infancy.

[9] Institute for Energy Economics and Financial Analysis, *Norway's Sleipner and Snøhvit CCS: Industry Models or Cautionary Tales?* (June 2023), https://ieefa.org/resources/norways-sleipner-and-snohvit-ccs-industry-models-or-cautionary-tales.

Further, carbonic acid tends to carry heavy metals such as arsenic, which *can* spoil drinking water supplies.[10]

The LCFS is effectively a gas tax, and forcing low-income communities of color to pay at the pump for DAC is unjust.

As CARB notes in its Standardized Regulatory Impact Assessment (SRIA) for the LCFS, the proposed amendments are expected to increase gas prices by as much as $1.83 per gallon, especially in the late 2030s and 2040s. In the same document, CARB acknowledges that these price increases are likely to impact disadvantaged communities more than others "because individuals living in these communities traditionally spend a larger share of their income on transportation fuels" and because "individuals in these communities may lack the means to effectively make use of ZEV technology as quickly as wealthier individuals, and therefore would rely on more expensive fossil fuels for longer."[11] CARB neglected to mention that people of color and people with lower incomes also tend to have longer commutes. These problems are even more acute in rural areas, where public transit tends to be minimal or nonexistent, and where needed services and retail like schools, doctor's offices, and grocery stores tend to be much farther from where people live. Moreover, charging infrastructure tends to be much scarcer in rural areas; some communities in the Central Valley and elsewhere lack access to the electric grid altogether because of disinvestment and environmental racism. Thus, low-income people of color living in disadvantaged rural communities are likely to be among the last to adopt expensive electric vehicles (EVs), will pay the most through increased gas prices, and can least afford to pay higher gas prices. While the LCFS is not technically a gas tax, its impacts are effectively the same, and gas taxes are inherently a regressive form of revenue generation for the reasons stated above.

The SRIA also notes that disadvantaged communities tend to benefit the most from the reduced emissions of heavy duty vehicles, which is both true and another way of saying that communities of color face the greatest harms from pollution in this sector (among others) in the status quo. However, offsetting emissions with DAC does nothing to reduce emissions and in fact brings new harms and risks to frontline communities, as discussed above, with projects likely to be located near rural, disadvantaged communities. So, under the current proposed amendments to the LCFS, rural disadvantaged
239.1 cont communities will pay the most through increased gas prices while being the least able to afford them, get no local benefits, and face local harms and risks from DAC, all to subsidize a speculative climate technology that, at least in the LCFS context, is more likely to harm our climate efforts than advance them. In short, low-income communities of color—especially in rural areas—would be forced to pay for their own degradation. That outcome is unjust.

This injustice flies in the face of AB 32, which requires that CARB, "to the extent feasible and in furtherance of achieving the statewide greenhouse gas emissions limit,… [e]nsure that activities undertaken to comply with the regulations do not disproportionately impact low-income communities."

[11] California Air Resources Board, *Standardized Regulatory Impact Assessment (SRIA): Proposed Amendments to the Low Carbon Fuel Standard Regulation* (Sept. 9, 2023).

The staff proposal would do the opposite: disproportionately harm low-income communities. CARB must chart a different course and remove DAC from the LCFS.

CARB must immediately cease crediting CCS projects that use captured carbon for enhanced oil recovery in harmony with the statewide prohibitions in SB 1314 (Limón 2022) and SB 905 (Caballero 2022).

239.2 cont In 2022, California prohibited the use of captured carbon for enhanced oil recovery in recognition of the local and climate harms of the practice, and it is incoherent for CARB to continue subsidizing the practice in other states. Apart from the hypocrisy of subsidizing outside of our state what is illegal inside it, the same reasons that we outlawed enhanced oil recovery in California demand that we immediately stop issuing LCFS credits for EOR using captured carbon outside the state.

Using captured carbon for EOR results in serious climate harms under the guise of climate action. When captured carbon is used for EOR, four times more carbon is emitted than is captured.[1] This is deeply troubling given that an estimated 80% of global captured carbon is being used to increase oil production.[2] Expanding EOR in the United States could result in an additional 400,000 barrels per day oil production by 2035, which would directly lead to as much as 50.7 million metric tons of net CO2 emissions annually.[3] Funded largely by taxpayers and—through the LCFS—car drivers, that is not a
239.2 cont climate solution but rather a fossil fuel subsidy. We should not use the LCFS as a fossil fuel subsidy, so we should discontinue this crediting practice immediately.

---

[3] Oil Change International, *Expanding Subsidies for CO2-Enhanced Oil Recovery: A Net Loss for Communities, Taxpayers, and the Climate (2017),* http://priceofoil.org/content/uploads/2017/10/45q-analysis-oct2017-final.pdf.

239.2 cont Further, the local impacts of EOR using captured carbon are significant. EOR is a threat to local and regional air and water quality, and using captured carbon only exacerbates those harms. Pressurizing oil and gas wells with CO2 leads to serious risks of leaks of not just carbon dioxide but also methane, hydrogen sulfide, and various air toxics and volatile organic compounds (VOCs), in addition to oil and toxic produced water. Further, CO2 can leak catastrophically from pressurized wells, leading potentially to serious harm and death because concentrated CO2 is a toxic asphyxiant that is heavier than air. This problem is not without history; although carbon capture has so far seen limited deployment, we've already seen a major leak. In 2016, a Wyoming school was forced to shut down for almost a year because old, plugged oil and gas wells leaked dangerous levels of CO_2 that had been injected for EOR.[12]

239.2 cont

Given the clear climate and local harms and utter lack of benefits beyond oil industry profits, as well as the illegality of the practice within the state, CARB must not delay in ending LCFS credits for enhanced oil recovery. While we recognize that the SB 905 rulemaking is gearing up and could also address this problem, that rulemaking is moving slowly at CARB, with little visible activity in the year and half since SB 905 was passed. Further, we see other changes to CCS crediting in the proposed amendments, and CARB would advance no public benefit by continuing crediting and subsidizing EOR while that rulemaking progresses, even as CARB makes other changes to the LCFS CCS protocol. Thus, CARB must end its fossil fuel subsidy for EOR under the LCFS in the current rulemaking.

*****

This rulemaking provides CARB the opportunity to improve the LCFS, bring it into closer alignment with principles of climate justice, and strengthen it as a climate tool. Or, CARB can double down on the extractive past. We urge CARB to revise the staff proposal to eliminate crediting for DAC and EOR using captured carbon because of the negative consequences for climate and for disadvantaged communities both in-state and across the nation.

Re: RNG Coalition's Comments on Low Carbon Fuel Standard Initial Statement of Reasons

Dear Mr. Botill:

The Coalition for Renewable Natural Gas (RNG Coalition) is a California-based nonprofit organization representing and providing public policy advocacy and education for the Renewable Natural Gas (RNG) industry.[1] RNG Coalition respectfully submits these comments to the California Air Resources Board (CARB) in response to the Proposed Amendments (Proposed Rule) to the Low Carbon Fuel Standard (LCFS) and associated Initial Statement of Reasons (ISOR).

We thank CARB staff for acknowledging the importance of continued RNG growth and share CARB's goal of supporting "methane emissions reductions and deploying biomethane for best uses across transportation." The biggest barrier to continued LCFS-driven methane reduction is the Proposed Rule's lack of overall ambition. We recommend that CARB focus on swiftly enhancing the program's goals to achieve the maximum technologically feasible and cost-effective greenhouse gas reductions from transportation fuels.

240.1 CARB should adopt an LCFS program target of at least 25% for the remainder of 2024 (and through
240.2 2025) to immediately reduce the program's credit bank to an appropriate level. CARB should also set
midterm targets in the range of a 30-44% reduction by 2030. The Automatic Accelerator Mechanism
240.3 should be allowed to trigger as early as possible, to guard against the case where the near-term target
step down in not sufficient to address the current oversupply.

Additionally, the specifics of the Proposed Rule do not fully alleviate stakeholder uncertainty about RNG's future role in the program. Our comments below explain the importance of continued expansion of the robust national framework for RNG accounting, further adjustments to the credit true up concept, and avoiding the dangers of phasing out avoided methane crediting without a replacement strategy to ensure methane emissions reductions from various organic waste streams.

Sincerely,

/S/
Sam Wade
Director of Public Policy
Coalition for Renewable Natural Gas

Table of Contents

1 Increased Program Ambition is Critical for Continued Methane Reduction and Growth in All Low Carbon Fuels

Given the LCFS credit surpluses over the last two years, a significant step-down in the Annual Carbon Intensity (CI) Benchmarks is critical at this time. Based on all recent market information to date, 2024 will have many more credits produced than deficits. This will cause the bank to continue to build rapidly, prices to fall, and low carbon fuel investment to stall.

CARB's goal should be to reduce this troubling trend and take advantage of the opportunity to promote greater use of low carbon fuel. The key to accomplishing this goal is setting the appropriate stringency trajectory for the CI Benchmarks and to avoid unnecessary price volatility as we go from large quarterly surpluses to quarterly deficits. Therefore, improved target setting has always been, and remains, the most critical topic in this rulemaking.

1.1 We Support the Target-Setting Analytical Work Conducted by the Consulting Firm ICF

Throughout this rulemaking, a diverse group of Clean Fuel voices has contracted with the consulting firm ICF to independently prepare and submit an analysis of what program targets are feasible. ICF has extensive experience modeling supply and demand in analogous clean fuel programs, both for governments and non-governmental organizations—including the Colorado Energy Office, Great Plains Institute, Oregon Department of Environmental Quality, Puget Sound Clean Air Agency, and for private clients. We encourage CARB to rely upon the results of the ICF analytical work as it represents the most comprehensive and realistic analysis of supply and economics of RNG available to the LCFS system, as well as for other low carbon fuels.

Key findings of the ICF work include the following:

- ICF recommends a "step down" of 10.5% to 11.5% in 2025 to achieve a target credit bank equivalent of 2-3 quarters worth of deficits. This is equivalent to a 2025 target of 24.25-25.25%.
- ICF recommends that the Automatic Acceleration Mechanism be considered for implementation as soon as 2026, rather than waiting until 2028. ICF also recommends that the first criteria for the Automatic Acceleration Mechanism be modified such that the mechanism is enacted when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year.
- ICF recommends that Staff increase transparency in credit price modeling so that stakeholders can better understand what is driving the magnitude of credit pricing and the patterns emerging from the data.
- ICF's analysis shows that the proposed changes to the fossil diesel baseline significantly change the relative stringency of the program's targets, when expressed as a percentage of baseline levels.

1.2 A 2025 Target of ≥25% is Needed to Address Current Oversupply Issues. This Level of Ambition Should also be Implemented in Q3 or Q4 of 2024, if Administratively Possible.

240.1a Based on the ICF work, we believe that it is appropriate to increase the program's benchmarks to set at least a 25% CI reduction below the 2010 Baseline in 2025. This should be sufficient to begin to draw down the credit bank, reestablish a demand for additional expansion in low carbon fuel supply, and therefore drive the necessary long-run amount of additional greenhouse gas abatement to reach the state's overall transportation decarbonization goals.

240.1b Further, starting this step down as soon as possible and avoiding unnecessary bank build is crucial. We recommend that CARB target the step down to occur on 7/1/2024 to a level of 25% below the 2010 baseline and maintain that level through 12/31/2025 (assuming CARB elects to retain the updated 2010 diesel baseline value and that the necessary administrative steps can be accomplished on this timeline).

1.3 A 2030 Target of 30% can be Achieved with a Lower Credit Price Trajectory than Predicted in CARB's Modeling of the Primary ISOR Scenario

240.2 ICF's work shows significantly different LCFS credit price outcomes than CARB's ISOR analysis of the primary scenario. We believe that ICF's outlook is better informed by the true near-term supply outlook across all low carbon fuels, deeper analysis of production costs, and a better understanding of the potential other areas of public policy support (e.g., federal biofuel and clean vehicle policy). Given that this deeper understanding demonstrates that it is possible to achieve greater mid-term reductions, we recommend that CARB continue to target at least a 30% CI reduction by 2030 and adjust their credit price forecasting to reflect ICF's input.

1.4 2030 Targets in the Range of 41-44% are Achievable. Additional Enhancement of the Program to Support all Low Carbon Fuels is In Line with Statewide Goals.

The ICF work also demonstrates that greater ambition is achievable in the 2030 timeframe—if additional adjustments are made to maximize opportunities for greenhouse gas reductions across RNG and all other types of the low carbon fuel. We note that CARB's primary Scoping Plan scenario targeted a 48% economy-wide reduction in greenhouse gases by 2030[2] and at least a 40% reduction is required by law.[3]

Since transportation remains the largest sector of greenhouse gas (GHG) emissions in California, and clearly additional low carbon fuel supply is feasible, we believe CARB should continue to try to expand the ambition of LCFS program targets and match the LCFS more closely to economy-wide goals.

1.5 Changes to Fossil Diesel Baseline Significantly Change the Relative Stringency of Program Targets

Per ICF's analysis, the Proposed Rule's decision to increase the CI of Ultra Low Sulfur Diesel from 100.45 g CO_2e/MJ to 105.76 g CO_2e/MJ has major unarticulated consequences. This change—especially without at least some analogous change for the N_2O performance of Renewable Diesel pathways—has a material impact on the program's ambition, when expressed as a percentage of that baseline.

240.4 ICF analysis suggests that this will yield substantially more credit generation than previously forecast. CARB should better justify this change in diesel fuel baseline—with respect to alignment between tailpipe emissions performance of vehicles using both conventional and renewable diesel—or be sure to correct for this factor more transparently during final target setting.

2 Additional RNG-Related Changes Are Needed to Improve Investor Confidence and Increase the Pace of Methane Emissions Abatement

Despite CARB staff's stated support for RNG throughout the informal workshop process (and in the ISOR) investors remain concerned about how the Proposed Rule shifts the LCFS's RNG crediting framework. The simple fact is that many anaerobic digestion (AD) RNG projects in planning and construction across North America currently rely on LCFS revenues to be built and operated. Without clear rational for RNG programmatic changes—and consistency in concepts between draft regulatory text, material presented in workshop slides, modeling tools, and statements by all levels of CARB staff—investors do not fully know how to respond to regulatory signals sent by CARB's Proposed Rule.

It took an almost decade-long history of LCFS credit being awarded to RNG projects, clear recognition of the methane reduction benefits across a variety of feedstocks, and consistent positive statements from CARB leaders before investors begin to seriously rely on this program to construct RNG projects. If CARB truly wants methane abatement from sources such as agricultural wastes to continue, and for new sources of RNG activity such as organic waste diversion from the municipal waste stream to develop they must reconvince the clean fuel investment community that RNG will remain a viable and important contributor to the LCFS framework.

2.1 CARB Correctly Continues to Acknowledge the Importance of Methane Reduction to Addressing Global Climate Change and the Benefits of RNG in Promoting Methane Reductions, Regardless of Location or End Use

Methane is a highly potent greenhouse gas with impacts greater than 80 times that of carbon dioxide over a 20-year period. The critical need to address methane as a potent short lived climate pollutant was well stated in CARB's 2017 Short Lived Climate Pollutant (SLCP) Reduction Strategy and echoed by many other leading authorities.[4]

The concentration of methane in the atmosphere is increasing at an alarming rate.[5] It is the second most important GHG, behind carbon dioxide, and it can and must be addressed quickly. There is no more effective and immediate step we can be taking as a planet to address climate change now than to aggressively and rapidly reverse emissions of fugitive methane from all sectors, including society's organic waste streams.

The Intergovernmental Panel on Climate Change (IPCC) continues to emphasize the importance of methane capture stating that, "reducing non-CO_2 emissions such as methane more rapidly would limit peak warming levels and reduce the requirement for net negative CO_2 emissions" and that, "strong,

[4] See our December 9, 2022, workshop comments for a more comprehensive list of expert bodies calling for near-term action on methane.

[5] See "Increase in atmospheric methane set another record during 2021", National Oceanic and Atmospheric Administration, Press Release, April 7, 2022. http://noaa.gov/news-release/increase-in-atmospheric-methane-set-another-record-during-2021.

rapid and sustained reductions in methane emissions can limit near-term warming and improve air quality by reducing global surface ozone."[6]

As shown in Figure 1, the IPCC lists at least four key GHG mitigation options that relate directly to RNG production and use, including reducing methane and N_2O in agriculture, reduce methane from waste/wastewater, bioelectricty (including bioenergy with carbon capture and sequestration) and—most importantly for LCFS discussions—biofuels for transport.

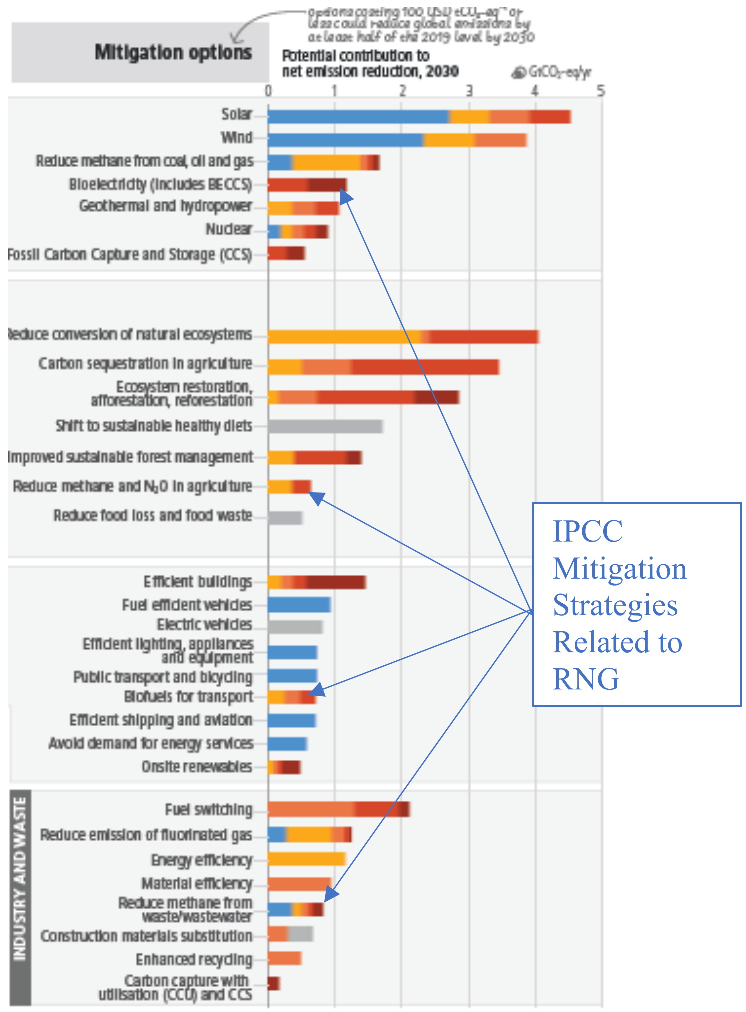

Figure 1. The IPCC Recommends Many Mitigation Options Related to RNG[7]

Further, last year—for the first time—the International Energy Agency (IEA) included a special section on Biogas and Biomethane in their *Renewables 2023 Analysis and Forecast to 2028* report.[8] Renewables

[6] IPCC, 2023: *Summary for Policymakers. In: Climate Change 2023: Synthesis Report. Contribution of Working Groups I, II and III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* https://www.ipcc.ch/report/ar6/syr/downloads/report/IPCC_AR6_SYR_SPM.pdf

[7] Ibid. See Figure SPM.7: Multiple Opportunities for Scaling Up Climate Action.

[8] International Energy Agency, *Renewables 2023: Analysis and Forecasts to 2028* https://iea.blob.core.windows.net/assets/96d66a8b-d502-476b-ba94-54ffda84cf72/Renewables_2023.pdf

2023 is the IEA's primary analysis on the Renewables sector, based on current policies and market developments. It forecasts the deployment of renewable energy technologies in electricity, transport, and heat to 2028 while also exploring key challenges to the industry and identifying barriers to faster growth.

In the special section[9] on biogas and biomethane, IEA states that, "in view of the urgent need to limit global temperature rise to 1.5°C, countries have begun to view biogas as a ready-to-use technology that can help accelerate decarbonisation in the short term, and they are therefore developing specific policies that include biogas as a key component in their energy transition strategies." The IEA also finds that, "using biogas and biomethane helps build a circular economy around residue and waste valorisation, contributes to rural economic development and creates employment. Plus, producing natural fertilisers as a co-product of biogas and biomethane production can augment farmers' income and help reestablish soil health by eliminating certain environmental impacts related to untreated manure use." The report also finds that:

> "In the United States, biomethane development has historically been driven by the transport sector and support schemes such as the Renewable Fuel Standard (RFS) and California's Low Carbon Fuels Standard (LCFS) applicable to fuels sold in California."

These findings are not new, but if CARB wants to build on this global recognition for smart LCFS policy design and expand influence in clean fuel conversations, they must continue to follow fact-based analysis from a science- and data-driven perspective. RNG remains a well-recognized global strategy to reduce emissions from organic waste sectors that can work in conjunction with other strategies—like waste reduction.

The United States Environmental Protection Agency (US EPA) has been tracking and attempting to incentivize anaerobic digesters with productive energy use since the inception of the AgStar program in 1994.[10] California efforts to install dairy digesters dates back (at least) to 2002 and the first round of funding for the California Energy Commission's Dairy Power Production Program.[11] Twenty to thirty years since the initial serious US exploration of this approach, while biogas recovery systems are technically feasible for over 8,000 *existing*[12] large dairy and hog operations across the US, AgSTAR estimates that still only 343 manure-based anaerobic digestion systems are installed and reducing methane emissions.[13] The LCFS needs to remain a key tool to help accelerate the critically needed action to reduce methane from these sources.

---

[9] https://www.iea.org/reports/renewables-2023/special-section-biogas-and-biomethane

[10] https://www.epa.gov/agstar

[11] https://calepa.ca.gov/history/

[12] We emphasize EPA's assessment of the number of existing farms that can support digesters to avoid triggering concerns that avoided methane crediting somehow leads to expansion or consolidation of farms. As discussed in more detail below, incentivizing anaerobic digestion as a clean fuel and manure management method does not incentivize manure production by dairy farmers or increases in herd size.

[13] https://www.epa.gov/agstar/agstar-data-and-trends

2.1.1 Avoided Methane Crediting Makes Agricultural RNG Projects Possible, Incentivizes Maximum Greenhouse Gas Capture During RNG Production

240.5 A fixed-year phase-out of avoided methane crediting—as included in the Proposed Rule—is simply not smart policy. Agricultural and organic waste diversion projects are heavily dependent on LCFS revenue for profitability, driven by the avoided methane components of their CI scores. During the informal workshop period of this rulemaking, many of our members have, on a confidential basis, individually supplied CARB with detailed economics for the development of dairy RNG facilities that clearly demonstrate that avoided methane crediting is critical to meet capital repayment requirements for new projects.

At current LCFS credit prices, a framework without avoided methane crediting does not even cover operating costs for existing agricultural projects in some instances. For projects where that is true—absent some new market that covers the cost of operations—existing digesters will not continue operating after their avoided methane crediting periods expire, potentially reversing progress made by the program.

2.1.2 Recognition of Avoided Methane is the Industry Standard in Europe

Opponents of recognizing RNG for avoided methane benefits often portray the CA LCFS's lifecycle analysis framework for methane from organic waste as if it is outside of the norm, or out of step with clean fuel policy in other leading jurisdictions. However, this is not the case. In fact, similar accounting was first pioneered in the European Union's Renewable Energy Directive (RED).

The Renewable Energy Directive is the legal framework for the development of clean energy across all sectors of the EU economy. The EU has found[14] that there is a clear need to scale-up RNG (biomethane) by 2030, as outlined in the *REPowerEU Plan* published in May of 2022.[15] Under that plan, the EU's biomethane production, either as biogas or its upgraded version as RNG, is targeted to reach 35 billion cubic meters per year by 2030.

Within the RED framework,[16] Annex VI provides Default GHG emission values and calculation rules for gaseous biomass fuels and their fossil fuel comparators.[17] As can be seen in Table 1, reproduced from that RED Annex, RNG from dairy manure for use as a transport fuel has carbon negative performance (e.g., achieves emission reductions greater than 100% relative to the emissions of the fossil fuel displaced).

---

[14] https://energy.ec.europa.eu/topics/renewable-energy/bioenergy/biomethane_en#:~:text=EU's%20biomethane%20production%20needs%20to,amounts%20to%20%E2%82%AC37%20billion.&text=This%20is%20a%20modal%20window.&text=Beginning%20of%20dialog%20window.,cancel%20and%20close%20the%20window.

[15] https://eur-lex.europa.eu/resource.html?uri=cellar:fc930f14-d7ae-11ec-a95f-01aa75ed71a1.0001.02/DOC_1&format=PDF

[16] https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX:02018L2001-20231120

[17] https://joint-research-centre.ec.europa.eu/welcome-jec-website/reference-regulatory-framework/renewable-energy-recast-2030-red-ii_en

Table 1. The EU RED Framework Continues to Recognize the Carbon-Negative Performance of Manure to RNG Transportation Pathways

BIOMETHANE FOR TRANSPORT (*)			
Biomethane production system	Technological options	Greenhouse gas emissions savings – typical value	Greenhouse gas emissions savings – default value
Wet manure	Open digestate, no off-gas combustion	117 %	72 %
	Open digestate, off-gas combustion	133 %	94 %
	Close digestate, no off-gas combustion	190 %	179 %
	Close digestate, off-gas combustion	206 %	202 %

Despite ongoing analogous scrutiny in Europe of anaerobic digestion of animal wastes—from similar voices as those active in California—the EU has found it is appropriate to continue this framework in the amending Directive EU/2023/2413, entered into force on November of 2023.[18] Embracing the true GHG
240.5 performance of RNG projects has been a recipe for successful RNG project buildout in both the CA LCFS and EU cases. CARB should continue to coordinate with European leaders on this important topic.

2.1.3 Avoided Methane Crediting Should Continue in LCFS Unless and Until a Realistic and Proven Replacement Policy is Implemented

Given the importance of the LCFS crediting in project viability, is unwise and irresponsible to propose an
240.5 arbitrary (tied to a fixed year) phase-out of avoided methane crediting without a detailed plan for developing a supporting replacement policy. Because of this fact, although better than prior proposals discussed during the workshop period, the Proposed Rule's treatment of avoided methane would still lead to significant project uncertainty and increases the potential for stranded assets—an issue correctly cited by CARB during the workshops as a key signal to be avoided.[19]

A California-only mandate for dairy manure methane control would likely drive "economic leakage" (unless LCFS support continued as well). Economic leakage in the environmental context occurs when a regulatory environment in one jurisdiction drives the migration of a key business sector to another region without similar regulations. This can lead to simply shifting the pollution location without any global reduction in GHGs. This is particularly likely to occur in markets with the demand for the product is steadily increasing, such as the market for milk products.[20]

[18] https://energy.ec.europa.eu/topics/renewable-energy/renewable-energy-directive-targets-and-rules/renewable-energy-directive_en#the-revised-directive

[19] See CARB's Presentation at the February 22, 2023, LCFS Workshop, slide 31. https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/lcfs_meetings/LCFSpresentation_02222023.pdf

[20] Office of Environmental Farming and Innovation, California Department of Food and Agriculture, March 29th 2022 Workshop Presentation, Slide 3, Dr. Amrith Gunasekara, Manager. https://ww2.arb.ca.gov/sites/default/files/2022-04/dairy-ws-session-2-CDFA.pdf

Although demand for liquid beverage milk is declining, and milk substitutes have emerged, US supply and demand for total milk products (both per capita and in aggregate) continues to grow.[21,22] These facts make it challenging for individual states, even a large dairy state such as California, to require control of manure methane unilaterally. However, it is possible that a federal requirement, or a mandate developed by a coalition of like-minded dairy states could be effective. We advise proponents of such a shift from "carrots" to "sticks" that, for such a transition to be effective it will require the cooperation of both the California dairy and RNG industries.

The current LCFS rule already contemplates an appropriate phase-out of avoided methane crediting once mandatory control requirements are in place. Section § 95488.9(f)(3)(B) of the Current Rule states that:

> "…in the event that any law, regulation, or legally binding mandate requiring either greenhouse gas emission reductions from manure methane emissions from livestock and dairy projects or diversion of organic material from landfill disposal, comes into effect in California during a project's crediting period, then the project is only eligible to continue to receive LCFS credits for those greenhouse gas emission reductions for the remainder of the project's current crediting period. The project may not request any subsequent crediting periods."

It is possible that a federal mandate to control manure methane could be developed, promulgated, and in effect in the 2040 timeframe. RNG Coalition would consider supporting such federal action if it treated anerobic digestion with productive energy use as best available control technology. However, we currently see no signs that such a federal effort is on the horizon.[23] We continue to support CARB requiring phase-out of avoided methane crediting once replacement policies are in place. However, we do not support the Proposed Rule's required phase-out of avoided methane crediting *without* a suitable replacement policy.

If CARB staff continues to treat RNG as a temporary solution that might be arbitrarily phased out—without regard to scientific analysis of ongoing emission benefits or development of a replacement strategy—investors will view RNG as a permanently "at risk" fuel, less favored by regulators and therefore not worthy of investment.

---

[21] USDA, *Dairy Products: Per Capita Consumption, United States (Annual)*, last updated 9/30/22. https://www.ers.usda.gov/webdocs/DataFiles/48685/pcconsp_1_.xlsx?v=4825
[22] USDA, *US Milk Production and Related Data*, last updated 8/15/22. https://www.ers.usda.gov/webdocs/DataFiles/48685/quarterlymilkfactors_1_.xlsx?v=4825
[23] Multiple states are moving to adopt LCFS policies that could provide a regional framework for addressing these emissions. Beyond expansion of LCFS-style policy no other serious state-level collaboration on manure management methane emissions has yet been proposed.

2.1.4 The Underlying Facts that Justify Avoided Methane Crediting to Ag RNG Projects Have Not Changed, CARB Should Rely on Extensive Prior Public Process and Leave the Current Framework in Place

While we always support additional stakeholder dialog around AD and RNG issues, we note that the facts on these issues have not changed and CARB has held extensive stakeholder outreach on these topics over the last decade, as required by Senate Bills (SB) 605 (Lara, 2014)[24] and SB 1383 (Lara, 2016).[25]

Senate Bill 605 required that CARB complete a comprehensive strategy to reduce emissions of short-lived climate pollutants (SLCP) in the state and hold at least one public workshop during the development of the strategy. CARB did so, developing the *Short Lived Climate Pollutant Reduction Strategy*[26] (SLCP Strategy) in March of 2017 with input from, "state and local agencies, academic experts, a working group of agricultural experts and farmers convened by the California Department of Food and Agriculture (CDFA), businesses, and other interested stakeholders in an open and public process".[27] Throughout this process, CARB "sought advice from academic, industry, and environmental justice representatives".[28] The SLCP Strategy contained extensive economic analysis of agricultural RNG projects[29] and found that:

> "The LCFS and the federal Renewable Fuel Standard (RFS) incentivize the use of renewable natural gas as a transportation fuel, creating large revenue potential within the dairy manure and organic diversion measures. These programs in particular can help support cost-effective projects to reduce methane from the dairy and waste sectors. Without the LCFS or RFS programs, additional sources for financial incentives and funding may be needed."[30]

SB 1383 further required that CARB provide a forum for public engagement on these issues by holding at least three public meetings in geographically diverse locations throughout the state where dairy operations and livestock operations are present. CARB went above and beyond this requirement and conducted almost two years of stakeholder engagement on these topics through a Dairy and Livestock Greenhouse Gas Reduction Working Group (Working Group).[31]

The three subgroups of the Working Group held 28 meetings that were open to the public for in-person and remote attendance and participation. The subgroup meetings typically included "information presented by subject matter experts and representatives from academia, industry, and non-governmental organizations, including environmental justice advocates" and environmental justice experts served on the subgroups.[32] The full Working Group—composed of the principals at CARB, the California Department of Food and Agriculture (CDFA), the California Energy Commission (CEC), and the

California Public Utilities Commission (CPUC)—held three public meetings. This led to a set of recommendations that helped inform the Current Rule.[33]

In March of 2022 CARB held another extensive public discussion of these topics, conducting an all-day workshop on *Methane, Dairies and Livestock, and Renewable Natural Gas in California*.[34] This workshop contained an in-depth presentation from CARB on LCFS mechanics.[35] In the same month CARB released an *Analysis of Progress toward Achieving the 2030 Dairy and Livestock Sector Methane Emissions Target*[36] after taking extensive public input[37] on a draft of that analysis. In the *Analysis of Progress* document CARB provided further analysis of LCFS and RFS environmental credit prices on ag AD project economics and continued to support AD as a primary means to reduce dairy manure methane emissions.

2.1.5 External Academic Analysis Shows that CARB's Strategy is Working

Realistically, if California wants to continue to lead globally on critical reductions in this SLCP from dairy and swine operations they cannot consider significantly upending their approach every few years, especially if the existing framework continues to demonstrate success. Recent UC Davis analysis shows continued implementation of California's incentive-based dairy methane reduction efforts will, by 2030, achieve the full SB 1383 40% reduction goal.[38]

This is a powerful and important finding. California's dairy industry, with support from the LCFS and other key programs (e.g., CDFA grants and the federal Renewable Fuel Standard), is on a course to meet the methane reduction challenge required by California law. In terms of both emission reduction and cost effectiveness, these are some of the state's most successful climate protection activities.[39]

Any further changes to the treatment of avoided methane crediting for agricultural AD in the LCFS
would likely directly contradict the state's prior existing emissions reduction strategy for dairy manure
240.5 methane, ignore the extensive stakeholder engagement work conducted by state agencies on these
topics detailed above, discourage a new RNG industry that has been coalesced primarily to reduce
greenhouse gas emissions, and most importantly disincentivize investment in one of the most effective
methods of methane abatement that the state fundamentally needs to use to reach its statutory goals.

---

[33] Including a recommendation to stabilize LCFS price support to ag RNG projects through a pilot financial mechanism that was never acted upon. Had such a provision been added projects would not be facing the current negative impacts of low prices.

2.1.6 There is No Evidence of a Perverse Incentive to Increase Farm Size from LCFS

LCFS credits from biomethane production does *not* incentivize manure production by increasing herd size. Even skeptical academic experts studying this issue[40] have found no empirical evidence to support the "perverse incentive" claims that underly some of the comments that continue to be made by uninformed anti-dairy voices.

Dairy RNG, at current transportation GHG market prices, generates only a small fraction of the gross revenue that is created by milk-sales. What is more, only a small share of that revenue goes to the farmer—the majority will be distributed to cover the costs of the digester developers, the gas marketer, the credit broker, end users (e.g., fleets adopting clean vehicles), the investors, and the banks. Meaning that the farmer does not make enough additional revenue from RNG to justify increasing herd size. However, the additional LCFS revenue from RNG production *is* critical to help defray the cost of an anaerobic digestor and encourage the transition toward a model of sustainable agriculture.

Even at higher prices, the LCFS incentive is unlikely to shift farm behavior. Dairy farmers are in the business of milk production and not RNG production. Agricultural voices that run dairy farms provided oral comment to this effect at the informal workshops and public meetings in direct response to questions from CARB Staff. RNG production at farms is usually handled by third-party project developers who constitute a large share of RNG Coalition's membership. These firms take substantial financial risk on these projects, historically because of explicit direction to do so from CARB and other California leaders.

Agricultural RNG projects are also a clear example that tests the thesis that investments based primarily on LCFS revenue—and GHG emission reduction benefits in general—is a feasible business model. Agricultural RNG development is one of the first major low carbon fuel industry built primarily around the LCFS program and it has only been successful because it was stood up by CARB based on the extensive public process described above. Major changes to this framework—without substantive new information—would undermine prior efforts to convince investors to make long-term capital deployment decisions based on LCFS credit value specifically, and California's climate strategies more
240.5 generally.[41] Therefore, CARB should leave the current avoided methane crediting framework in place.

2.2 A Full Credit True-up Remains Necessary to Properly Recognize the True Environmental Performance of RNG Pathways

We support the Proposed Amendment's inclusion of a "Credit True Up" after Annual Verification. When implemented properly, such a concept can ensure that the LCFS program correctly accounts for the full GHG benefits all fuel pathways produce. However, we believe the Proposed Amendment's true up language may be mis-drafted as it appears to *not* allow true ups during the temporary pathway period.

---

[40] Smith, Aaron, *"Are Manure subsidies Causing Farmers to Milk More Cows?"* April 8, 2023. https://agdatanews.substack.com/p/are-manure-subsidies-causing-farmers?r=i2qe&utm_campaign=post&utm_medium=web

[41] For the initial years of the LCFS, prospective low carbon fuel producers included anticipated credit revenue in financial models and the investors would ignore or heavily discount the LCFS line item, due to perceived change in law risk (colloquially called "stroke of the pen" risk).

This is confusing because, at both October 2020 and August 2022 LCFS Workshops, CARB Staff proposed providing a credit true up to correct for under crediting to pathway holders *only* during the period where a project is using temporary CI scores at the outset of their credit generation. At the time, CARB workshop material stated that such a limited true up would help reduce the pressure on CARB from developers to process LCFS applications quickly.

We continue to support a full true up to verified actual CI performance for all pathways (temporary, provisional, and fully certified).[42] Dairy Manure Digesters (and other biological systems) experience substantial increases and decreases in gas production due to weather, livestock herd changes, and other factors that are not present in other fuel pathways. Because the carbon intensity of the gas from these systems is calculated against a quantity of avoided methane emissions, these variations in biogas production necessarily result in outsized changes in the digesters' carbon intensity (CI) scores every year. Under the current structure of the LCFS (prior to the changes proposed in this rulemaking), all dairy digesters pathways experience the following negative impacts:

1. Substantial underestimation of greenhouse gas benefit (and associated lost revenue) during the temporary CI period.
2. Substantial risk of underestimation of greenhouse gas benefit (and lost revenue) each year during annual verification.
3. Substantial risk of LCFS enforcement, including risks of fines or potential pathway cancellation, due to no fault of the pathway holder.

These consequences are an unavoidable outcome of CARB's overly conservative approach under the Current Rule to dairy digester pathways (and some other pathways with biological feedstocks). As we will describe below, no amount of careful management, conservative pathway assumptions, or other actions can fully protect a digester under the Current Rule—and the Proposed Rule's changes alleviate some, but not all, of these concerns.

All three of the current negative impacts can be substantially mitigated or even eliminated with one simple policy change. Namely, if pathways were allowed to fully "true up" their LCFS credit generation to their actual CI score, once that score was knowable based on actual greenhouse gas performance data, all the problems are resolved.

The current LCFS regulation requires an annual verification to determine the true CI score, relative to the certified CI score. But the result of that annual verification is that pathway holders can only give up
240.6 credits if their actual CI score goes up—they cannot also gain credits if their verified CI score goes down. We believe that, absent some manipulation or misrepresentation, the exchange should go both ways. With proper safeguards around the timing of the true up and potentially some requirement to hold credits in reserve, this policy can serve to encourage very low carbon pathways whereas the current policy discourages very low carbon fuels in favor of less variable fuels. We describe in detail the justification for correctly addressing each of these impacts below.

[42] See our comment letters dated January 7, 2022, August 8, 2022, and September 18, 2022, submitted during the informal workshop period.

2.2.1 Analysis of Impact #1: Additional Changes to the Proposed Rule are Needed to Address Understatement of GHG Reductions During the Temporary CI Period

New dairy digesters in California must apply to CARB staff for pathways to generate LCFS credits. Assuming no major problems with the application, it currently takes a new digester startup 24-27 months to receive from CARB a provisionally certified LCFS pathway due, primarily, to CARB pathway processing timelines.

Most dairy digester provisionally certified Carbon Intensity (CI) scores are between -250 and -425 grams CO_2 equivalent per MJ. During the period where the applicant is waiting to receive its site-specific, provisionally certified score, CARB will usually allow the project to generate credits under a Temporary Fuel Pathway Code (TFPC) at a score of -150. That TFPC code allows a digester project to generate .219 LCFS credits per MMBTU of injected biomethane, which is substantially less than the 0.401 credits that a typical California -350 CI dairy pathway would create.

A digester must usually share the first block of credits generated (regardless of CI) with the dispensing natural gas vehicle fueling station that creates the vehicle fuel. So, the net credits per MMBTU of gas that a digester can create with a TFPC is severely discounted as compared to a provisionally certified pathway. As shown in the Table 2 below, a digester operating under a TFPC makes only 46% as much LCFS revenue as compared to one operating under a provisionally certified pathway. In effect, the two-year delay in processing the application forces the digester to receive 54% less credit (and thus less revenue) than the actual value of greenhouse gas reductions that the project has generated, according to the CA GREET model.

The reductions are real, and calculated according to CARB's requirements, but the delay in processing the application means that the project is not recognized for the reductions it generates. Even once the site-specific score (e.g., -350) is known based on actual data, the LCFS regulation does not allow the project to go back and create credits at the score for the period where it used the -150 TFPC. During the startup period for a typical 3,000-cow California digester, this undercounting incorrectly misses over 16 thousand metric tons CO_2e of emissions benefits driven by the LCFS. This also translates to lost revenues equal to approximately $1,310,400 for the project, assuming an LCFS credit price of $80/credit.

Table 2. Dairy Digester Pathways Lose Significant Value When Using a Temporary Pathway

	CI Score	Credits/MMBTU	Dispensing Cost	Credits to Digester	MMBTU/ quarter	Net Credits/quarter	$/Credit	$/quarter	Quarters awaiting Pathway	
Temporary Pathway	-150	0.219	-0.063	0.156	11,250	1,755	$80	$ 140,400	8	$ 1,123,200
Certified Pathay	-350	0.401	-0.063	0.338	11,250	3,803	$80	$ 304,200	8	$ 2,433,600
									Lost Revenue	**$ 1,310,400**

In some cases, it is possible to store the RNG by not dispensing it as CNG while awaiting LCFS pathway certification. But RNG may only be stored for three quarters under the LCFS, while pathway certification takes 8-9 quarters. So even with perfect foresight, a digester can only store a minor fraction of its gas pending certification. Furthermore, storage is expensive, and it prevents the digester from realizing any revenue, which is needed in the early stages of a project lifespan for operations, maintenance, and debt service.

<u>True Up Solution</u>: CARB's existing policy is to allow the project to generate credits at a -150 TFPC, followed by eventual provisional certification of a project-specific CI score. This initially conservative

policy is sound. However, after 24-27 months, the CI analysis nearly always reveals that the project has generated substantially more greenhouse gas reductions than the -150 score at which the project generated temporary credits. An easy fix would be for CARB to allow the project to "true up", at the time of provisional pathway certification, and generate additional credits for all prior reporting periods where it used the -150 TFPC.

As described above, CARB staff previously workshopped the option of making such a limited true up to address the temporary period. However, the ISOR proposal is unclear on how and when a true up
240.6 would occur during this period. We recommend that this uncertainty be corrected, or that CARB otherwise justify—in response to this comment in the Final Statement of Reasons—why dairy derived RNG and other clean fuels are not being recognized for their true greenhouse gas performance in the program during the temporary period.

2.2.2 Analysis of Impact #2: The Proposed Rule Correctly Addresses Substantial Lost Revenue by Allowing for a True Up Each Year During Annual Verification.

Once a new dairy digester has secured a provisionally certified LCFS pathway, the project can generate credits each quarter using that CI score. At the end of every year, the project must perform an annual verification to see whether its actual CI score over the prior 24 months was higher or lower than the provisionally certified CI score.

The need for annual verification is a proven tool to ensure accuracy of GHG performance in the LCFS (and similar programs), but the policy implementation of verified actual values under the current rule is lopsided (especially in the case of highly variable CI feedstocks such as manure used in anaerobic digesters). These projects cannot control the weather, which greatly impacts the CI modeling of baseline methane emissions via the Methane Conversion Factor. As shown on Table A.5 from the *Proposed Tier 1 Simplified Calculator for Biomethane from Anaerobic Digestion of Dairy and Swine Manure (Proposed Dairy Tier 1 Calculator)*,[43] methane conversion factors can vary by as much as 10x across the temperature range.

Nor can the project control the number and type of livestock present at the host site, which greatly impacts both the baseline calculation and the amount of biogas produced by the project. Table 3 below (labeled A.1 and A.2 in the *Proposed Dairy Tier 1 Calculator*) shows the variability of volatile solids production and biogas production potential, among animal types.

[43] https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/ca-greet/t1_biomethane_ad_dairy_swine_manure_simplified_calculator_v12192023.xlsm

Table 3. Various Animal Types Have Different Volatile Solids and Biogas Production Potential

Table A.1 and A.2: Typical Average Mass ($Mass_L$), Volatile Solids, and Maximum Methane Potential of all Livestock Category			
Livestock Category (L)	**Livestock Typical Average Mass (TAM) in kg**	**VS_L (kg/day per 1,000 kg mass)**	**$B_{o,L}$ (m^3 CH_4/kg VS added)**
Dairy cows (on feed)	680	11.41	0.24
Non-milking dairy cows (on feed)	684	5.56	0.24
Heifers (on feed)	407	8.44	0.17
Bulls (grazing)	874	6.04	0.17
Calves (grazing)	118	7.70	0.17
Heifers (grazing)	351.5	13.96	0.17
Cows (grazing)	582.5	8.89	0.17
Nursery swine	12.5	8.89	0.48
Grow/finish swine	70	5.36	0.48
Breeding swine	198	2.71	0.35

Most other LCFS fuel pathways have much more control over their CI inputs. Liquid fuel production CIs are not as impacted from weather and seasonal feedstock animal population. Even leaving aside all other operational variables that might apply to digesters, these two components are sufficient to cause the CI of a manure digester project to vary by over 100 points from year to year.

If the annual verification reveals that the actual CI score was lower (more negative) than the provisionally certified score, the project should be eligible to claim credits for the difference, but is not eligible to do so under the Current Rule. Just like during the temporary CI period described above, the project will have created more greenhouse gas reductions than it will receive revenue for.

On the other hand, if the annual verification reveals that the actual CI score was higher (less negative) than the provisionally certified CI score, the project already has to pay back credits to CARB under the current rule (and would have to pay back 4 credits for every one credit exceeded under the Proposed Rule). The CI of a dairy digester changes every year. Thus, each year the project will either under or over perform the CI that was verified the previous year. So, digesters essentially pay a “variability penalty”. Table 4 below shows a digester where the actual score—as determined by CA-GREET and verified by a third party—averages out to -350 over 10 years. However, the CI score available to the project over the first ten years (either certified or TFPC) averages to a -306. But since the project is in each year forced to generate credits at its worst performance level, the project is actually paid at a -285 CI under the Current Rule.

Table 4. Under the Current Rule Ag Digesters are Subject to a "Variability Penalty"

Year	TFPC or Certified Score	Actual (Verified) Score	Monetized Score*
1	-150	-350	-150
2	-150	-365	-150
3	-350	-260	-260
4	-260	-310	-260
5	-310	-405	-310
6	-405	-295	-295
7	-295	-375	-295
8	-375	-385	-375
9	-385	-380	-380
10	-380	-375	-375
AVG	**-306**	**-350**	**-285**

The net result of this policy is that highly negative CI pathways receive substantially fewer LCFS credits than the greenhouse gas benefits they actually create. Thus, project developers are incentivized to develop less carbon negative pathways that are more stable, because more negative pathways must pay a "variability penalty" under the Current Rule.

240.6 We Support Components of the ISOR Proposed True Up Solution, We Don't Support 4-to-1 Penalty: We support the provisions in the proposed rule where, if the verified CI is lower than the certified pathway, the project will generate additional credits based on the incrementally lower verified score using backward-looking actual performance.

This true up process should be automated by CARB in the LRT-CBTS system for all fuels. In this situation, because of the true up, the total credits awarded would be equal to the true value of greenhouse gas emissions reductions, which is historically the stated intention of the LCFS program. Consequently, highly variable CI scores would not pay a variability penalty (assuming they adopt an appropriate margin of safety), and project developers would be encouraged to seek lower CI scores rather than methods of ensuring steady/less-variable CI scores.

However, we do not support the Proposed Rule's approach to the case where a verified CI is higher than the certified CI. The Proposed Rule requires that the quantity of deficits generated by CI exceedance be assessed as four times the difference between the verified operational fuel pathway CI and the reported CI (multiplied by the quantity of fuel reported using that fuel pathway during the applicable year).[44] Therefore, if over crediting occurs by one ton the pathway holder must "pay back" four credits. This is overly punitive and unsymmetrical. We recommend that, instead, if the verified CI is higher than

240.7 the certified CI, the project should simply repay CARB for any excess credits claimed, and not be subject to any further enforcement liability (see next section) unless there is malfeasance or other such cause.

[44] See proposed text in § 95486.1(g).

2.2.3 Analysis of Impact #3: The Proposed Rule Addresses Risk of Unwarranted LCFS Enforcement Resulting in Fines or Pathway Cancellation, but 4-to-1 Penalties are Unnecessary and Arbitrary

As we've described above—and highlighted since at least 2020 for CARB in informal workshop feedback—a dairy digester pathway's CI will go up or down every year. So, each year during annual pathway verification when the actual CI performance from the previous 24 months is determined, if a project selects it's true initial CI based on historical data, there is a 50% chance that the next year will be higher than that mark, and a 50% chance that it will be lower. Thus 50% of the years, under the Current Rule a given CI pathway will be vulnerable to potential CARB enforcement action—including penalties and possible loss of pathway—due to no fault or malfeasance by the pathway holder. This situation presents a risk that no digester developer can quantify, and that gives pause to investors who are funding the expansion of dairy digesters and the resulting reduction of methane emissions.

But what tools exists to mitigate this risk? The only tool available in the Current Rule is to input a "margin of safety" in the CI score. So, for example, if the digester owner shown in Table 2 above expects that over the course of 10 years it's verified CI will fluctuate between -405 and -260, then the digester owner should set the margin of safety input (available in the CI calculator tool) each year so that they claim credits at a -250. Assuming the owner has calculated properly, and assuming no surprises occur, this digester can make it through 10 years without exceeding that CI. However, this digester was truly achieving -350 average verified reductions, and only being paid for an average score of -285 (due to TFPC effects). With this added "margin of safety" the average CI score the digester will achieve over 10 years is now -230. See Table 5 below.

Table 5. Dairy Pathway Holders Must be Overly Conservative to Avoid Enforcement Risks Under the Current Rule

Year	TFPC or Certified Score	Actual (Verified) Score	Monetized Score*	Monetized Score to Avoid NOV
1	-150	-350	-150	-150
2	-150	-365	-150	-150
3	-350	-260	-260	-250
4	-260	-310	-260	-250
5	-310	-405	-310	-250
6	-405	-295	-295	-250
7	-295	-375	-295	-250
8	-375	-385	-375	-250
9	-385	-380	-380	-250
10	-380	-375	-375	-250
AVG	**-306**	**-350**	**-285**	**-230**

So, enforcement risk is avoided by accepting an even larger "variability penalty" The project is receiving credits at an average score of -230 when it's GREET verified score is -350. Under these circumstances, it makes less economic sense for business to attempt to create ultra-low carbon fuel pathways, if a third of that benefit can never be monetized.

240.18 We Support the Proposed Rule True Up Solution to Address Unwarranted Enforcement Risk: We support how the Proposed Rule helps address this issue as it retains the margin of safety framework but allows for a true up to verified CI performance.

We note that CARB still retains all its enforcement tools to intervene if a pathway holder is engaging in misrepresentation, delayed or incorrect reporting, or does not meet strict verification obligations. But in cases where the pathway holder has done nothing other than fully comply with CARB's requirements, and operated using best practices, yet later finds the CIs have naturally changed, enforcement action (and underreporting of environmental benefit) is not beneficial.

2.3 Deliverability Language Creates a Barrier to Imports, Should Not be Adopted in the LCFS

The Proposed Rule's deliverability requirements are still problematic for RNG development. The ISOR suggests that CARB staff is patterning these changes on concepts from California's Renewable Portfolio Standard (RPS) requirements. Stating that:[45]

> "For projects that break ground after Dec 31, 2029, staff is proposing to require deliverability starting January 1, 2041 for pathways that include biomethane used in CNG vehicles or starting January 1, 2046 for biomethane used as an input to hydrogen production. In particular, staff proposes to align with the deliverability policy for biomethane in the California Energy Commission's Renewables Portfolio Standard (RPS) program (Public Utilities Code section 399.12.6) and the California Public Utilities Commission 1440 program. Specifically, the concept is to require demonstration that eligible biomethane is carried through common carrier pipelines that physically flow within California or toward end use in California. Such pipelines must flow toward California 50% of the time on an annual basis, as defined by the current RPS eligibility guidebook."

240.8 This language is not an improvement in reporting that would somehow provide greater accuracy, or certainty that imported RNG molecules can be traced to California Natural Gas Vehicle (NGV) fuel tanks. As described in more detail below, it is simply an arbitrary requirement—with no additional environmental benefit or grounding in the physical gas system.

Such a requirement might, in practice, prohibit *all* imported RNG from being used in California for LCFS, due to cost and administrative complexity. The existing RPS approach includes a set of complex tests that essentially serve to ensure that no imports can meet the requirements. The factual record from the RPS clearly demonstrates that this language creates a barrier to imports in practice. As shown in Figure 2,[46] no new importing facilities were built to serve the CA RPS, after the deliverability language was imposed through Assembly Bill 2196 (Chesbro) in 2012, despite in-state project development continuing.

[45] See ISOR page 31.

[46] Figure derived from California Energy Commission RPS data available here: https://rps.energy.ca.gov/Pages/Search/SearchApplications.aspx

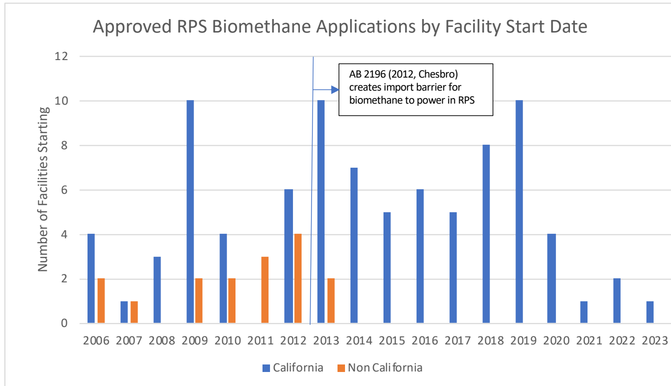

Figure 2. No New Importing Facilities Have Been Built to Serve the California RPS Since AB 2196 Deliverability Language was Established

Protectionist language in portions of the RPS program design—including the de-facto ban on imported RNG—have not succeeded in creating a well-functioning California-only electric grid, able to function entirely using only in-state renewable energy and without imports and exports. Instead, the California Independent System Operator is *currently trying to expand electricity markets regionally* to make it easier to adopt more renewables.[47] We encourage CARB to learn from this example, continue current LCFS practice, and not to close our boarders to imported RNG supply. Harmonizing RNG markets rules with other US states—just as California is now attempting to do to maximize the use of renewable electricity—is a better outcome both for the climate and for California fuel consumers.

Unlike the RPS, the LCFS has been a strong driver of both in-state and out-of-state RNG project development. Because in-state projects have also historically been receiving support through grant programs,[48] the amount of in-state RNG production has been increasing rapidly in California over the past few years and now enjoys a greater proportionate domestic (in-California) market share than many other types of energy. For example, we believe we import more than 90% of our conventional gas in California but only ~77% of our RNG.[49]

Given that California clearly benefits from broad North American and global energy markets for other types of energy—and the recent trend toward significant increases of the in-state supply of RNG—we question why CARB would propose eliminating imported RNG eligibility from any portion of the North American gas system. In the next section we describe how the gas system functions and how the Current Rule's "book and claim" provisions for RNG fit well with the realities of the gas system.

---

[47] The California Independent System Operator is "continually pursuing strategies to manage higher amounts of renewable energy into the electricity system. Studies by the ISO show that expanding the energy market across the western US region would accelerate California's efforts to meet the state's ambitious clean energy goals, while saving costs, lowering emissions, and promoting economic growth." See: http://www.caiso.com/informed/Pages/RegionalSolutions.aspx

[48] For example, see: https://www.cdfa.ca.gov/oefi/ddrdp/ and https://calrecycle.ca.gov/climate/grantsloans/organics/

[49] See our December 9, 2022, comments for more details on how this estimate was derived. We encourage CARB to publish import share of RNG using the LCFS data as they do for liquid biofuels in the LCFS Data Dashboard.

2.3.1 Because it is Physically Interchangeable with Fossil Natural Gas, Renewable Natural Gas can be Distributed in the Same, Longstanding Natural Gas Pipeline System that has Served California for Decades

Natural gas currently flows throughout the United States depending on shifts in production, demand, weather, export pricing, and natural gas balancing. All major North American gas pipelines are interconnected, sharing gas flow and balancing, which can be contrasted with the power sector that is currently a more balkanized system, with some limits on wheeling between regions—despite the efforts mentioned above to increase interconnection of the power grid.

When RPS limitations were developed, gas was just beginning to come from all over the country to California. The map in Figure 3 below shows cross-country flows, dating back to 2011, illustrating the interconnectedness of the natural gas pipeline system in the United States at that time.[50]

Natural gas has long been distributed through these pipeline systems tracking volumes being injected and withdrawn throughout the entire system. These volumes are carefully tracked, as the pipeline system has state and federal regulatory oversight and third-party pipelines have metering throughout the system. Not only does this create a robust and liquid market for physical gas delivery across North America, that market already optimizes moving gas from supply to demand in a least cost (and lowest GHG)[51] fashion.

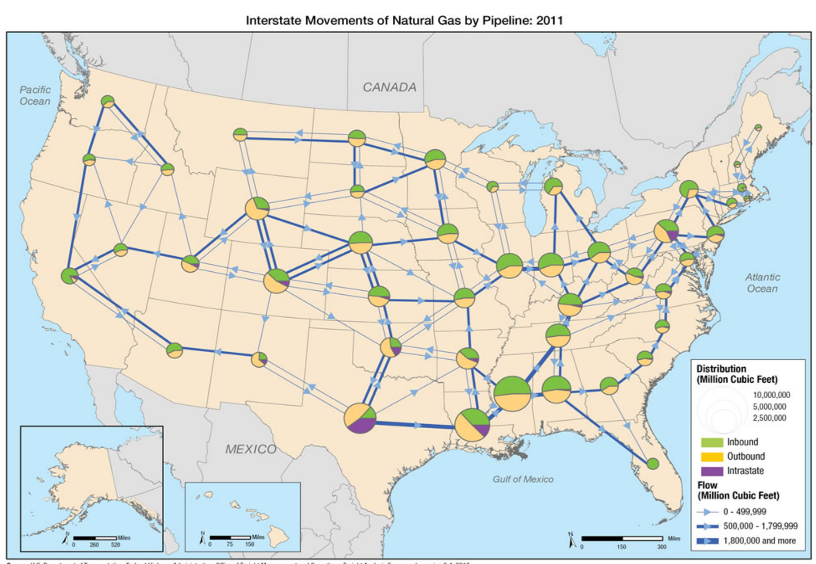

Figure 3. The Natural Gas System Has Interconnected Flows Across North America

---

[50] U.S. Department of Transportation Federal Highway Administration, *Interstate Movements of Natural Gas by Pipeline: 2011 Map*, https://ops.fhwa.dot.gov/freight/freight_analysis/nat_freight_stats/interstatenatgas2011.htm (last modified Mar. 23, 2020).

[51] Moving gas requires additional energy and emissions from compression stations and potential methane leakage. These factors are already correctly accounted for in the LCFS CI modeling, which assumes physical gas flow from source to sink, regardless of the ability to trace actual molecule path. This provides a fair and appropriate disincentive that recognizes GHG disbenefits of moving gas from projects located farther from California, all else equal.

The conventional gas market did away with point-to-point service long ago and created trading hubs and flexible receipt and delivery points to give suppliers a variety of options for getting gas to market. Generally, price signals are sent, and liquid trading occurs where the gas is produced, traded, and consumed without having to track individual gas sources throughout the value chain.

2.3.2 This System Can Move Gas Bidirectionally Across North America, therefore, a 50% Flow Requirement is Arbitrary and Unjustified.

Since the RPS provisions were developed, North American pipelines have evolved even further toward one unified system. For example, natural gas can now flow from the Northeast region to all areas of the United States, from Texas to California, and from the Rockies to California. The entire pipeline system in the United States is interconnected and in many cases is now bidirectionally flowing. Examples are provided below.

According to EIA,[52] the Appalachian Basin's large shale formations—which were developed after the RPS proposal was implemented—have dramatically changed gas flows. The Appalachian Marcellus and Utica formations:

- Accounted for 34% of all U.S. dry natural gas production in 2021. On its own, the Appalachian Basin would have been the third-largest natural gas producer in the world in the first half of 2021, behind only Russia and the rest of the United States.
- Since the development of these formations (which cover parts of Kentucky, Maryland, New York, Ohio, Pennsylvania, Virginia and West Virginia) there has been an increase in natural gas flows and pipeline infrastructure from the Mid-Atlantic and Ohio regions to the West and other regions.
- From 2008 to 2020, total pipeline takeaway capacity from the Northeast increased from 4.5 Bcf/d to 24.5 Bcf/d. Most of the increase in takeaway capacity happened between 2014 and 2020, when pipeline capacity increased by 16.5 Bcf/d.

In January 2022, for the first time in its history, the Rocky Mountain Express (REX) natural gas pipeline—which moves bidirectionally from Ohio to Wyoming—had larger gas flows westward than eastward, indicating growth in supply in the eastern U.S. and use to serve demand in the western U.S.[53] Ruby Pipeline interconnects with the Rockies Express Pipeline to bring Appalachian natural gas to the West Coast.[54]

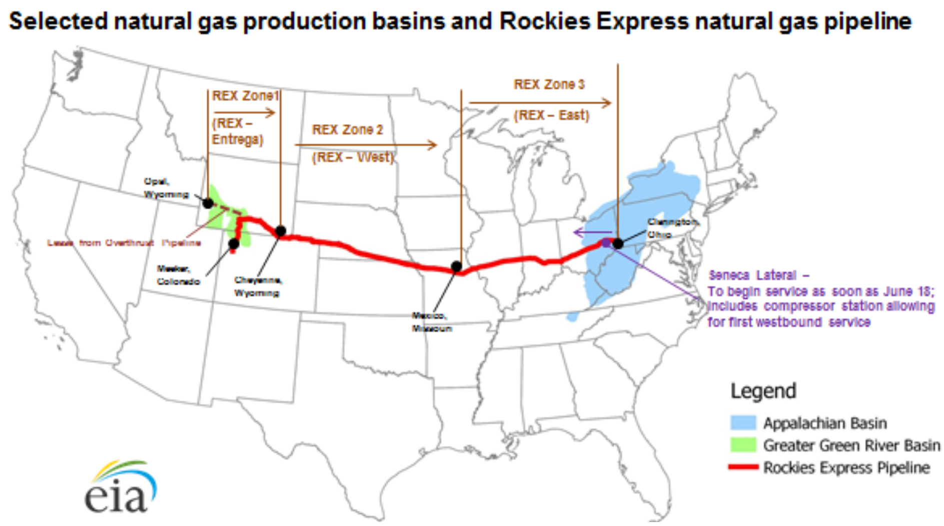

Figure 4. Rocky Mountain Express Pipeline Flows Bidirectionally and Can Bring Gas from East to West[55]

Any successful framework for RNG must build off existing gas system realities, but it does not need to assume that the gas system is static or that RNG supply should be limited to regions that currently supply most of the conventional gas to California. Repurposing existing natural gas infrastructure to rapidly deliver a blend of low-carbon fuels, including RNG, across North America will complement initiatives to cut demand for gas through expanding energy efficiency and electrification.

As demonstrated above, gas system flow can shift over time. Fossil gas demand reduction and RNG supply growth will surely also create large changes in the gas system and the map of the system today is unlikely to match the map of the system in 2040. However, RNG is still a nascent market and cannot be expected to dramatically impact gas flows immediately, unless and until fossil gas use also declines. Therefore, pipes that currently supply less than 50% flow toward California may eventually be adjusted to be capable of supplying more than this percentage. Conversely, prevailing flows may shift over time
240.8 and pipes that currently serve California with more than 50% of their flow may not do so in perpetuity. Given this uncertainty, RNG developers could not invest in a long-lived (e.g., 20-year) asset, based on the LCFS value, if the program has such a 50% flow test. The prevailing flows in gas pipelines are completely outside of the control of any one developer and thus represents an unacceptable risk unless the facility is sited in California.

Finally, the 50% flow concept is not applied to limit delivery of any other fuels in either the Current or Proposed Rule. Analogous non-sensical requirements could certainly be conceived for other fuels. For example, the majority of rail traffic on a given line could be required to move in the direction for California (perhaps even when not specifically carrying ethanol, to create a full analogy).

Alternatively, will California stop accepting fossil gas deliveries through pipelines that do not flow toward California 50% of the time? Imagine how catastrophic such a limit would be when supply crunches occur, such as the one that occurred in Southern California in late 2022.[56]

---

[56] U.S. Energy Information Administration, *Daily Natural Gas Spot Prices in Western United States Exceed $50.00/MMBtu in December*, January 24, 2023. https://www.eia.gov/todayinenergy/detail.php?id=55279

While RNG opponents may desire to create administrative complexities to artificially increase costs or impose barriers to RNG use, CARB should not be swayed by such arguments. The existing CA RPS language is simply a canard to disincentivize out-of-state RNG development, distract from the legitimacy of RNG's environmental benefits, and turn a key advantage of RNG (it's compatibility with the existing gas system) into a perceived weakness. We strongly recommend that CARB avoid implementing
240.8 arbitrary RNG deliverability requirements—and treating fossil gas preferentially to RNG—simply because RNG must currently share the gas system with fossil gas.

2.3.3 Guarantee of Origin Systems (Book-and-Claim) are the Industry Standard in Europe

As described above, because it is not possible to physically segregate delivery of renewable gas once it is intermingled with fossil gas in the pipeline system, other chain of custody methods must be utilized. "Book and claim" is a guarantee of origin concept that was pioneered in the European Union's renewable fuel policies. A key advantage is that such accounting lowers administrative barriers and facilitates matching sources of renewable fuel production to demand centers.

Given the physics of how gases quickly intermix in pipeline systems, no feasible alternative exists to book and claim accounting for RNG. Requiring redundant RNG-only pipeline infrastructure and/or physically segregated trucking/rail of gas would clearly increase GHG emissions and the non-climate environmental impact of RNG delivery. Requiring an RNG developer to hold long-term firm pipeline capacity from production source to end use does not ensure that the renewable molecules flow in that path. Instead, it only adds an extra layer of cost because it does not allow market participants to take advantage of liquid supply trading hubs and pipeline displacement, which can bring transportation costs down significantly.

The renewable gas strategies of leading European countries, such as Denmark[57] which currently have around 40% RNG in their gas system (and expect to reach 100% by 2034), should be more closely studied by CARB as it relates to these issues. Denmark's Green Gas Strategy[58] prioritizes free trade of green gases across borders and states that:

> "When a biogas plant feeds biogas into the gas system, it is mixed with other gas. In the gas system, both biogas and natural gas are mixed to form a uniform gas. In order for the gas supplier to prove the origin of the gas supplied to the final customer, guarantees of origin are used. Energinet issues guarantees of origin, thereby ensuring that it can be documented that a consumed volume of gas is matched by an equivalent production of green gas. This system prevents double counting of renewable energy, allowing companies and other consumers to pay for green gas."

There are now ongoing efforts to move from national RNG registries to a European-wide registry to track RNG volumes using the book-and-claim concept. The European Renewable Gas Registry (ERGaR) was established as an independent documentation scheme for tracking RNG and other renewable gases distributed along the European gas network.[59] Recently there was also a €3 million EU-funded project

57 https://ens.dk/sites/ens.dk/files/Naturgas/groen_gasstrategi_en.pdf

58 Ibid.

59 https://www.ergar.org/abous-us/

known as REGATRACE[60] to develop an efficient trading system based on the issuance and trading of Guarantees of Origin (GO) for RNG.[61] The final report[62] from this process contains the following statements:

> "The European Renewable Gas Registry (ERGaR) was started by and continues to be composed of long-established registries and stakeholders of the biomethane and renewable gas industry. A growing imbalance between biomethane production and consumption in several countries necessitated crossborder transfers. Individual bilateral solutions were established, but in most cases member states refused to grant any benefits to imported biomethane. As such, it has been in its best interest to create a system in which the cross-border transfer of gas certificates could be both technically facilitated and recognised in the target country.
>
> GOs serve only for consumer disclosure, which means that the "green gas" attribute is separated from the gas physical volume. This model is called "book and claim" and is useful for setting the path to the European biomethane market because the GOs help document the volumes being produced, distributed and consumed."

2.3.4 CARB Should Promote a Unified North American RNG Registry System

Given that Europe is expanding RNG trade, built on a clear guarantee of origin system (book and claim), one centralized registry, and the same conceptual principles that CA LCFS currently uses, we think North America can achieve the same objective if leading jurisdictions, such as California, continue to support such a framework.

It is a better outcome for the climate if we start by setting up one well-functioning North American system for RNG, rather than create unnecessary delays with balkanized programs (that likely must be consolidated at some point in the future, in line with the European experience).

The RNG Coalition continues to support development of one North American registry for tracking RNG production and end use to ensure no double counting of RNG volumes. The leading registry system tracking RNG and other forms of renewable thermal energy is the Midwest Renewable Energy Tracking System (M-RETS).[63] The use of M-RETS to supplement LCFS reporting would reduce administrative
240.9 burden on CARB staff and offer California a chance to harmonize the design of such systems with other jurisdictions who are now undertaking similar RNG-supportive policies. Use of M-RETS aligns well with the existing RNG accounting methods in the LCFS.

[60] https://www.regatrace.eu/

[61] Given the recent gas crisis in Europe, the EU now plans to increase biomethane deployment to displace 17 bcm of gas imports in the short-term (approximately equivalent to all natural gas demand for power production in California). https://ec.europa.eu/info/strategy/priorities-2019-2024/european-green-deal/repowereu-affordable-secure-and-sustainable-energy-europe_en

[63] https://www.mrets.org/m-rets-renewable-thermal-tracking-system/

2.3.5 The Current LCFS RNG Framework Aligns with Fuel Use Reporting in the US Renewable Fuels Standard and with State-level Partners. This Alignment Should be Enhanced, not Dismantled.

A key market reality today is that most RNG projects need both LCFS and RIN credits to be viable. Currently only NGV end uses offer full alignment between both programs, which is why that end use has been so popular for RNG thus far. Unlike California's RPS, the US EPA's Renewable Fuel Standard has consistently created a strong framework for RNG growth and is a much better model for CARB's LCFS to continue to align with.

Deliverability rules in the RFS program have long recognized that once RNG and fossil gas is co-mingled there is no way to ensure deliverability of just the subset of renewable molecules. For a recent example of EPA's analysis of this issue, the preamble[64] for the RFS "Set" rulemaking explicitly stated that:

> "When RNG moves through a pipeline system for distribution, the RNG is mixed with a much larger proportion of fossil natural gas using the same system. The two natural gases—one derived from renewable sources, the other from fossil sources—are fungible at that point. Consequently, by the time the natural gas is used to fuel a vehicle, there is no meaningful way to identify which molecules of methane were originally sourced from biogas and which came from fossil sources. As discussed above, and in light of this dynamic, when EPA introduced RNG as a transportation fuel in the RFS program in the Pathways II rule, we set up a system whereby the demonstration that RNG was used as transportation fuel relied on accounting protocols, recordkeeping requirements, and requirements for contracts and affidavits attesting that a specific volume of RNG was used as transportation fuel, and for no other purpose."

EPA correctly recognized that efforts to trace deliverability (e.g., based on securing gas transmission rights or tracing prevailing pipeline physical flows) still cannot guarantee that the RNG molecules flow along preferred paths (or separate paths from fossil molecules). Therefore, any attempts to impose such tests simply increases compliance costs for parties creating and using RNG without achieving any additional environmental benefit.

The current LCFS's book-and-claim rules allow for consistent claims in RNG volume across the RFS and the LCFS. Deviating from this approach for imports will inherently create misalignment in claims, administrative confusion at both reporting entities and CARB, and fewer financially viable projects. The US EPA may also eventually enhance the incentive for the biogas/RNG resource to be sent toward electricity generation for electric vehicle use (eRINs), use in hydrogen production, and as a bio-intermediate to producing liquid fuels. We recommend that CARB consider even further alignment
240.19 between the LCFS and RFS, especially with respect to matching biogas/RNG electricity pathways to EV fleets and hydrogen pathways, if they wish to see these end uses for RNG grow.

Following US EPA and California's currently positive example, book-and-claim accounting has emerged as the preferred method to track RNG in all analogous North American Clean Fuel programs. For example, the Canadian Clean Fuel Standard, the Oregon Clean Fuel Standard, and the Washington Clean

[64] US EPA, Federal Register, Vol. 87, No. 250, Friday, December 30, 2022, Proposed Rules. See page 80637. https://www.govinfo.gov/content/pkg/FR-2022-12-30/pdf/2022-26499.pdf

Fuel Standard all use book and claim for RNG projects as well as for electricity and hydrogen. Gas utility procurement programs for RNG use similar concepts.

Given that the California LCFS pioneered such reporting in North America, it should not abandon it now. The fact that analogous programs are close to being established in other states reduces the likelihood of California being overly reliant on imported RNG in the long term. Each new state that adopts an LCFS-style policy creates a new demand center, which regional supply will likely consider serving first before California (assuming similar credit pricing).

Finally, in summary, many fuels in the LCFS have a relatively high import market share and all fuel categories credited by the LCFS involve lifecycle emissions (and emission reductions) that occur outside of California. For example, a significant share of California's grid mix of electricity (~44%)[65] is produced from conventional natural gas, over 90% of which is imported.[66] Reducing *all* GHG emissions (including the upstream emissions performance) of *all* fuels (including imports) continues to be a critical advantage of the lifecycle approach taken by the LCFS. RNG imports should not be singled out from other fuels for
240.19 different treatment, especially considering the critical importance of reducing methane to mitigate the effects of near-term warming.

3 The Auto Acceleration Mechanism Should Be Able to Trigger Earlier, if Needed to Address Current Oversupply

CARB should adopt an Automatic Accelerator Mechanism (AAM) feature that dynamically responds in the event of future sustained and significant CI reductions by tightening programmatic stringency. The RNG Coalition supports the creation of credit-price-band mechanisms in tradeable environmental credit markets—both generally and as conceptually discussed in the Proposed Rule. Such features can increase investor certainty in credit markets.

CARB's proposed timeline for implementing the AAM is currently that 2028 will be the first year for which the AAM can amend CI reduction targets. We recommend that 2025's performance should be able to trigger the AAM. As we understand the AAM proposal, a 2025 data-year triggering would be able to impact CI targets in 2027, or one year prior to when the ISOR currently proposes. We recommend adjusting the implementation timeline accordingly. Essentially, the AAM should be allowed to trigger as
240.3 early as possible, to guard against the case where the step down in not sufficient to address the current oversupply.

4 Improvements in Pathway Processing and Updates to Tier 1 Calculators and CA-GREET

4.1 We Support the Revised Tier 1 Calculators and Focusing on Improving Pathway Processing Times

We were pleased to see CARB staff's efforts to improve Tier 1 calculators for this rulemaking. We support the majority of RNG pathways being Tier 1 in the future and we remain committed to working

---

[65] See Table 1-2 of CARB's 2023 *Carbon Intensity Values for California Average Grid Electricity Used as a Transportation Fuel in California and Electricity Supplied Under the Smart Charging or Smart Electrolysis Provision* *https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/fuelpathways/comments/tier2/2023_elec_update.pdf?_ga=2.5711222.418438686.1678413739-188703561.1626734718*

[66] https://www.energy.ca.gov/data-reports/energy-almanac/californias-natural-gas-market/supply-and-demand-natural-gas-california

with CARB to help improve processing times and reduce administrative complexity for RNG pathways. We also note that simplification of pathway processing is critical for other jurisdictions to adopt LCFS analogs.

4.2 Recognition of Methane Benefits of RNG Projects Diverting Organic Material from Landfills Should be Revisited and Expanded

Both CARB and US EPA have mandatory emission control requirements for landfills that help reduce methane emissions, yet research literature suggests that many landfills still contribute methane emissions at rates that are much higher than previously estimated.[67] A 2019 study by NASA JPL estimates that landfills' contribution to the state's methane emissions is double current estimates – approximately 41% of all methane point source emissions in California.[68] RNG Coalition and a wide swath of other stakeholders have been raising these issues with CARB for more than three years.[69]

LCFS can help address methane from organic waste handling through better recognition of the benefits of RNG projects that divert organics from landfills and into dedicated digesters. Better quantification of the methane benefits of avoided landfilling and incenting such reductions in the LCFS should be a key focus for CARB, rather than considering arbitrary dates for eventual sunsetting of avoided methane crediting.

We support and appreciate the change for years 1-3 in the *Tier 1 Calculator Biomethane from Anaerobic Digestion of Organic Waste* acknowledging the fact that significant methane emissions occur from the open face of the landfill. However, maintaining the average 75% assumed capture rate for the remaining years is inaccurate and does not align with current science, most notably EPA's October 2023 EPA findings that 61% of methane from landfilled food waste escapes to atmosphere (39% capture rate).[70]

Given that EPA was the source for prior capture rate assumptions (with the 75% capture coming from a 1997 EPA study), EPA's much more robust and up-to-date results should be immediately adopted and the 2023 EPA findings of 39% capture rate incorporated into the Tier 1 calculator.

4.3 The Ability to Increase Methane Capture Rates and Reduce Flaring Through Landfill RNG Projects Should be Recognized

[67] This fact should be noted by those that believe a mandate to control is the sole solution that should be employed for other sources of fugitive methane, such as agricultural manure methane emissions.

[68] Duren, R.M., Thorpe, A.K., Foster, K.T. et al. California's methane super-emitters. Nature 575, 180–184 (2019). https://doi.org/10.1038/s41586-019-1720-3

[69] See our LCFS Workshop comment letter dated November 5, 2020 and Anaergia's LCFS Workshop comments dated September 19, 2022 for examples.

[70] United States Environmental Protection Agency, Office of Research and Development, October 2023, *Food Waste Management: Quantifying Methane Emissions from Landfilled Food Waste* https://www.epa.gov/system/files/documents/2023-10/food-waste-landfill-methane-10-8-23-final_508-compliant.pdf

LCFS recognition of projects that improve methane capture efficiency at landfills beyond regulatory requirements could help improve capture efficiencies of the methane that results from the waste in place at existing landfills.[71,72]

As CARB has workshopped preliminary concepts for potential improvements to the Landfill Methane Regulations CARB staff analysis found that approximately two-thirds of landfill gas collected statewide is currently flared and identified an additional 30 to 50 Californian landfills that could capture sufficient methane each year to cost-effectively utilize gas for energy generation.[73] We are disappointed to see
240.6 that no effort has been made, thus far, to better incentivize productive use of landfill gas under the LCFS framework in this rulemaking.

4.4 Assuming One Annual Lagoon Cleanout for Dairy and Swine Manure Pathways is an Understandable Simplification, however it Will Significantly Harm Many RNG Pathway CIs

We note that the Draft Rule's changes to the *Proposed Tier 1 CI Calculator for Dairy and Swine Manure Biomethane* includes a simplifying default assumption related to lagoon cleanouts (a factor that impacts baseline methane emissions). Under this change, it appears that all projects would be required to assume at least one cleanout would have occurred annually in September, even if this does not match the actual historical practice of the farm in question.

Many dairies have a series of lagoons large enough that annual clean outs of accumulated solids are not necessary. This can take several forms, for example, when one or more lagoons are full the farm stops filling them and begin filling others, leaving the full one(s) to dry out (via evaporation in hot weather) which often takes 1-4 years after the lagoons have ceased receiving fresh manure. During this time one or more other lagoons may be in use. When the unused lagoon(s) are sufficiently dry the remaining solids would be hauled out with loaders and/or excavators. Such practices should not be modeled as a cleanout since the volatile solids have all degraded by the time the dried solids are removed. This baseline practice of no lagoon cleanouts is most likely to occur in regions with warmer and more arid conditions primarily storing manure in thin, liquid forms, including California and other parts of the Southwestern US.

Assuming one lagoon cleanout annually in the base case will reduce methane avoidance and thus
240.10 increase the CI for these projects. This will, in turn, reduce the credits issued to many dairy and swine RNG projects—in some cases significantly.

We understand CARB staff is proposing this change primarily to respond to calls from anti-dairy voices to be more conservative in CI scoring, and to improve administrative simplicity of evaluating baseline

---

[71] Page 234 of the 2022 CARB Scoping Plan States that, "While reducing organic waste disposal is the most effective means of achieving reductions in waste sector methane, strategies to reduce emissions from waste already in place in landfills also will play a role in achieving near-term reductions." https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

[72] For an example protocol evaluating the installation of an automated collection system that can increases landfill gas collection efficiency above that obtained with standard collection methods see: https://americancarbonregistry.org/carbon-accounting/standards-methodologies/landfill-gas-destruction-and-beneficial-use-projects

[73] CARB, *Preliminary Concepts for Potential Improvements to Landfill Methane Regulation Public Workshop Slides*, May 18, 2023, https://ww2.arb.ca.gov/sites/default/files/2023-05/LMR-workshop_05-18-2023.pdf

conditions for these projects. We support the goals of improved administrative simplicity, especially if it can lead to increased pathway processing times. However, modeling lagoon cleanouts where they do not truly occur will lead to an underestimation of avoided methane emissions benefits and, therefore, cause a barrier to investment in livestock-manure-to-RNG projects. On the other hand, ignoring lagoon cleanout could result in overestimating the baseline methane emissions, which we understand that CARB staff feels they must avoid at all costs.

In summary, this simplifying assumption on lagoon cleanout practices will make a material impact on CI scores for many RNG projects to the detriment of their total crediting. While we accept this change for the sake of simplicity, we urge CARB to avoid any further pushes to be overly conservative. We also believe that this example of enhanced conservativeness in the avoided methane calculations of the Tier 1 calculator makes it even more critical that the true up concepts discussed above are also implemented in this rulemaking to correct another source of under crediting. RNG pathways simply will not remain economically viable if subjected to additional arbitrary and unjustified "haircuts" that fail to recognize the true GHG benefits of this fuel.

4.5 Fix the Default Electricity Emissions Regional Refactoring Issue in the Tier 1 Models Identified by U.S. Venture

We support addressing the issue raised in U.S. Venture Inc.'s February 12, 2024, comment letter. U.S. Venture points out that default electricity emission factors within CARB's Tier 1 calculators, which are derived from the CA-GREET model, may be off by a significant amount. As CARB adjusts the National
240.11 GREET calculator, which uses a NERC region map (11 regions) to determine electricity emission profiles, to one that uses the eGRID subregions (27 regions), there appears to be an error in this refactoring that needs to be corrected.

4.6 Renewable Natural Gas Facilities Need Flexibility to Source Renewable Power as an Input to RNG Production

The Proposed Rule should continue to introduce flexibility to experiment and find the optimal mix of inputs and outputs in all forms of low carbon fuel production. A significant share of energy demand at many RNG facilities is electricity used to power gas cleanup equipment. It is not always possible to have low-CI electricity sources that are directly connected to the RNG production facility "behind the meter", as required in Section 95488.8(h)(1)(B) of the current rule.

The challenge of generating one's own renewable power is heightened by the cost and risk multipliers that are triggered when one must simultaneously develop both an RNG production facility and a renewable power project capable of matching the load of the RNG plant. We recommend that flexibility
240.12 be added to allow RNG to source low-CI electricity—either under specific Power Purchase Agreements (PPAs) or Book-and-Claim renewable energy certificates (REC) purchases.

4.7 All Biomethane Pathways Should Include the Option to Model Power Generation Matched with Electric Vehicle Use as a Finished Fuel

We continue to recommend that all Tier 1 calculators allow electricity generation as a finished fuel to
240.12 facilitate matching with electric vehicle (EV) use. Alternatively, CARB could develop a Tier 1 calculator that takes a RNG pathway as an input and converts it to electricity for use in EVs. This would create a strong analog with the approach taken for hydrogen. CARB has expressed a desire to see the

biogas/RNG resource utilized outside of natural gas vehicle applications (including into fuel cells and other power generation equipment), creating appropriate Tier 1 calculators would help to facilitate this.

4.8 Liquid Fuel Production and Electricity Production Needs Flexibility to Be Able to Source RNG as an Input

Under existing LCFS provisions, Low-CI electricity supplied as a transportation fuel, e.g., used to power EVs, can be sourced flexibly using RECs or via a qualifying Green Tariff program. Similarly, we recommend that an accounting system be developed to allow both liquid fuel production facilities and pipeline-connected gas-fired electric generation (matched to EV use) to source RNG as a method to reduce CI scores for these fuels.

As CARB explores the implementation of more stringent carbon reduction targets, the use of book-and-claim accounting for inputs like RNG and electricity will likely prove invaluable for its success. This is particularly true if opportunities for renewable gases as an input for transportation fuels like sustainable aviation fuel (SAF) and renewable diesel (RD) are expanded.

With CARB's proposal to obligate fossil jet fuel to generate deficits within the LCFS, the demand for low carbon fuels across different feedstocks and end uses will inevitably increase, with SAF as an end use being a priority for certain airlines. Currently, there are no provisions in the regulation allowing book-and-claim accounting for offsite biomethane used as feedstock for SAF and RD production. We believe that allowing the book-and-claim of RNG to SAF/RD will not only accelerate reaching these targets, but it
240.13 will also help to reach the roughly 800 million gallons of SAF required to meet Governor Newsom's 20% clean fuels adoption target, 1.5 billion gallons in 2030 to meet the AB 1322 (Rivas) goal, and 3.2 billion gallons by 2045 to meet the 2022 Scoping Plan target.

5 Other Minor Suggested Edits and Clean Up

§ 95501(h) – Less Intensive Verification - The Proposed rule allows for less intensive verification for electricity Quarterly Fuel Transaction Reports (QFTR) only, which we support. However, site visits for *all* QRTF are generally unnecessary. Verification site visits for a QFTR are primarily comprised of a visit to an entity's headquarters or other location of central data management and comprises reviewing electronic records. The site visit can easily be done virtually—as was approved, observed by CARB LCFS Staff, and successfully completed during COVID. Alternatively, CARB could rely upon the discretion on the third-party verification body to determine if a visit is required, if they deem a less intensive verification will not suffice. By allowing less intensive verifications for QFTRs, there will be a reduction in required travel and the associated GHG
240.14 emissions from them. Therefore, LCFS should allow for less intensive verifications for all QFTR reports.

240.15
- § 95488.9(b) – Table 8. The temporary fuel pathway codes for hydrogen derived from RNG seem unnecessarily high. For example, compressed or liquified hydrogen derived from dairy or swine manure has a temporary CI of 40, yet registered pathways under the Current Rule producing hydrogen from such RNG are often highly carbon negative. We request that CARB clarify this discrepancy in the Final Statement of Reasons, and we note the connection between this issue and the need for the full true up described above.

240.16
- § 95491.2(b)(2)(C) – Force Majeure Events. If a site has a force majeure event and shuts down for months, the CI score will be heavily impacted, and at that point it will be too late to add an

240.16 cont additional margin of safety to the score. We ask CARB to clarify how such situations will be addressed in the Final Statement of Reasons. The types of events CARB are implying might occur in this section may already be captured in shutdown logs provided to the verification body along with the data captured during the events (typically null or zero values). Thus, it seems unnecessary and unduly burdensome to require special reporting for such events within 90 days, given the remote nature and geographic location of many alternative fuel facilities and especially given that production during these events is minimal to zero, which is readily captured in the reported dataset(s).

- § 95501(13)(A) - Review of Missing Data Substitution. CARB, like many regulatory bodies, has previously recognized the use of "reasonable temporary methods" to address data gaps, noting operational realities result in varying gaps that can be reliably filled in reasonable ways that consider the context of each situation. RNG Coalition urges CARB to continue to allow those participating in the LCFS to be able to use "a reasonable temporary method," rather than prescribing the limited data substitution tactics specified under 95491.2(b)(2)(B)'s Table 13 unless such additional flexibility is already allowed under the use of an "Executive Office approved alternate method".

240.17

6 Conclusion

RNG Coalition appreciates the opportunity for continued engagement on these topics. CARB has an opportunity to provide clarity and investment certainty through additional changes to the Proposed Rule, leveraging renewable gas production to help reduce methane emissions, improve organic waste management, and decarbonize California's transportation sector—or any other sector that CARB deems appropriate. We thank CARB for your continued work toward this end and look forward to the conclusion of a robust and effective LCFS rulemaking.

Re: WSPA Comments on Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Ms. Sahota,

The Western States Petroleum Association (WSPA) appreciates the opportunity to comment on the California Air Resources Board's (CARB) proposed amendments and related 45-day rulemaking documents for the Low Carbon Fuel Standard (LCFS) program. WSPA is a non-profit trade association that represents companies that import and export, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California and four other western states, and has been an active participant in air quality planning issues for over 30 years.

WSPA has engaged with CARB throughout the LCFS rulemaking process, and previously submitted comments in response to CARB's 2022 and 2023 LCFS workshops. Those comments are incorporated into this letter by reference and are also attached.[1,2,3,4,5,6]

GENERAL COMMENTS

Fiscal Impact of Proposed Amendments

CARB's proposed amendments are projected to significantly increase the cost of California gasoline, despite ongoing and serious supply constraints related to transportation fuels in California. CARB's Standardized Regulatory Impact Analysis (SRIA) estimates that the proposed amendments to the LCFS program will potentially increase the price of gasoline by an average of $0.37 per gallon between 2024 and 2030, and further increase the price of gasoline by $1.15 per gallon between 2031 and 2046.[7] While CARB's Initial Statement of Reasons (ISOR) describes its cost estimates as "conservative,"[8] CARB's analysis underestimates revenue impacts to the State's gas tax revenues. CARB estimates that tax revenues will decrease by $29.2 million[9] due to "increase[s] in volume of
241.1 renewable gasoline, ethanol, and renewable diesel fuel sold in the State,"[10] but this estimate does not capture the significant revenue impacts associated with a 90% reduction in gasoline demand,

which is the forecasted impact of the proposed amendments. The gas tax provides substantial funding for California's infrastructure projects, which will be needed to meet California's electrification goals and address associated increases in electricity demand. CARB has also adopted several rules designed to reduce gasoline demand (e.g., Advanced Clean Cars II, Advanced Clean Trucks, Advanced Clean Fleets), but has neither assessed the full impacts of this change nor has it addressed how to replace this funding, which leaves the State in a vulnerable position.

These significant cost increases conflict with ongoing efforts by the California legislature to ease cost burdens associated with California fuels. Senate Bill (SB) X1-2 (2023) directs State agencies to evaluate measures to ensure that petroleum and alternative transportation fuels are adequate, affordable, reliable, and equitable. The California Energy Commission (CEC) estimates that the LCFS Regulation already adds 11 cents per gallon to the cost of California gasoline.[11] The impacts of these price increases are significant for California consumers – California continues to face serious supply constraints for transportation fuels, leading energy affordability to be a pressing priority for many Californians. The legislature recognized the importance of these impacts in enacting SB X1-2. CARB must therefore ensure that its revised LCFS program does not further compromise the supply reliability of critical transportation fuels, a consequence of which could increase energy costs and further burden California drivers, conflicting with clear legislative priorities in SB X1-2.

CARB's proposed LCFS Amendments may exacerbate these cost issues by constraining the credit generation for fuels, such as crop-based biofuels and hydrogen, while simultaneously and significantly increasing and potentially accelerating program stringency. Credit prices are also approaching a maximum – CARB estimates that credit prices will reach the program ceiling in 2025 and 2026. As CARB emphasized in 2020, prices beyond this point would create "potential adverse impacts to California consumers."[12] CARB's proposed program amendments would add new limits to credit generating opportunities just as LCFS credit prices approach the price ceiling, exacerbating cost impacts. These combined measures undermine the program's cost-effectiveness, in violation of Health and Safety Code (HSC) § 38560, which requires CARB to ensure that its program amendments are cost-effective. Similarly, HSC § 43018 requires CARB to adopt only necessary, cost-effective, and technologically feasible regulations. California Government Code § 11346.2(b)(4) also requires CARB to consider "reasonable alternatives to the regulation that would lessen any adverse impact on small business," and reasonable alternatives that are "less burdensome." As part of these alternatives, CARB must consider "overall societal benefits, including reductions in other air pollutants, *diversification of energy sources*, and other benefits to the economy, environment, and public health."[13] To comply with these provisions, WSPA urges CARB to revise its proposed program amendments to create a more cost-effective, less burdensome regulatory program that protects a diverse energy portfolio.

As part of preserving a diverse energy portfolio, CARB must ensure that the proposed amendments
241.2 do not burden ethanol development. As drafted, proposed § 95488.9(g)(1)(A) states: *"All feedstocks at the point-of-origin must be certified by January 1, 2028. Fuel quantities reported under fuel pathways utilizing feedstocks not certified by January 1, 2028, must be assigned the ULSD carbon intensity [(CI)] found in Table 7-1 of the LCFS regulation."* This requirement is overly broad and may require ethanol feedstocks to meet certification and tracking requirements, which would significantly increase the cost and burden of ethanol and disincentivize ethanol development. This would conflict with HSC § 38560's mandate that CARB adopt measures "to achieve the maximum technologically

[13] HSC § 38562.

feasible and cost-effective greenhouse gas emission reductions from sources." Ethanol is critical for achieving lower-CI for gasoline with limited to no substitutes for ethanol to achieve today's CI reductions. CARB should therefore clarify that these requirements *do not* apply to ethanol, and
241.2 account for costs related to ethanol production and importation in assessing the program amendments.

Additionally, CARB should ensure that the program amendments preserve a *technology-neutral* approach in order to maximize cost-effectiveness. CARB's proposal to phase out avoided methane crediting and project-based crediting treats different low-CI technologies inconsistently, disincentivizing certain investments and foregoing important emissions benefits. For example, in Book-and-Claim accounting, low-CI process energy would need a direct connection, while low-CI
241.3 electricity and hydrogen used in transportation would not require this additional step. Removing existing crediting mechanisms risks stranding assets while discouraging investments in other zero-emission and low-emission technologies, which will lead to increased program costs and will decrease emissions benefits associated with methane reductions. This approach also runs counter to existing programs incentivizing the development of projects to address Short-Lived Climate Pollutants. We encourage CARB to instead study the potential impacts of imposing deliverability requirements before adding untested regulatory restrictions.

The LCFS program centers around a market-based approach to emissions reductions from all transportation fuels. Preserving flexibility in how credits are spent enhances the trading program and protects investments made by private companies to help make the program both successful and replicable. By contrast, imposing spending requirements, like those on electric vehicles, impedes private sector investment in alternative fuel technologies and infrastructure, such as hydrogen refueling and alternative uses for biomethane, which are essential for achieving California's greenhouse gas (GHG) reduction goals.[14,15]

Unsubstantiated Need for Crop-based Feedstock "Guardrails"

241.4 WSPA supports CARB's decision not to include arbitrary caps on crop-based feedstocks or fuels. As WSPA noted in prior comment letters, these caps would limit proven GHG reductions strategies that are delivering significant GHG reductions today. Any concept of a cap on a specific fuel type conflicts with Health and Safety Code § 38560's mandate that CARB adopt measures "to achieve the maximum technologically feasible and cost-effective greenhouse gas emission reductions from sources."[16] For the same reasons, any such cap would also likely run afoul of Health and Safety Code § 38562's requirement to consider "diversification of energy sources, and other benefits to the economy, environment, and public." Staff has also confirmed that CARB "received limited data, analysis and supporting documents" and that there was no majority of stakeholders presenting a compelling argument in favor of such a significant programmatic change.

While CARB has declined to include a "cap" on crop-based feedstocks, CARB is now proposing to impose "sustainability guard rails" that may limit the supply of crop-based feedstocks used in the production of biofuels. As part of these guardrails, the feedstock supply chain would be required to comply with a resource-intensive, duplicative third-party process to ensure that crop-based and
241.5 forestry-based feedstocks are not sourced on land that was forested after January 1, 2008. This process would increase costs associated with biofuel production. CARB explains that these guardrails are intended to "reduce the risk that rapid expansion of biofuel production and biofuel feedstock demand could result in deforestation or adverse land use change."[17] However, CARB has

[16] *See also* HSC § 43018.
[17] ISOR at 32.

not provided data demonstrating that there is a sustainability issue that needs to be addressed. The details of this concept were introduced late in the rulemaking process based on general concerns raised by commenters, and CARB has not received sufficient public input from key stakeholders – including California's transportation fuel producers who rely on crop-based feedstocks to support the delivery of alternative transportation fuels for Californians.

Existing LCFS program measures and related federal programs provide sufficient guardrails to address potential land use changes associated with crop-based feedstocks. The LCFS program "uses land use change emissions estimates…[to] make fuel pathways from crop-based feedstocks more carbon intensive," thereby discouraging the use of crop-based fuels and incentivizing "waste-and-residue-based" feedstocks.[18] In addition, the federal Renewable Fuel Standard (RFS) program[19] imposes mapping and tracking requirements for foreign sourced crops, as well as specific forest-based feedstock requirements. This program mandates that crop-based feedstocks be sourced from existing agricultural land cleared or cultivated prior to December 19, 2007. For feedstocks grown outside of the United States or Canada, entities must map and track the point of origin to ensure that this restriction is met.[20] For feedstock grown in the United States or Canada, EPA verifies compliance when it issues a Renewable Volume Obligation.[21] Regulated entities are also prevented from obtaining federal Renewable Identification Number (RIN) compliance credits for converting land not already in use as of 2007.[22] Further, all feedstock used to produce compliance renewable fuels must meet the definition of "renewable biomass." Given these existing requirements, CARB's proposed tracking and certification requirements would be duplicative.

241.5 The additional measures proposed by CARB will create an unnecessary burden for transportation fuel producers and may impact the availability of alternative transportation fuels. Requiring farmers to obtain third-party certification may increase feedstock prices, impacting biofuel production costs and increasing overall fuel prices in California. Requiring farmers to provide documentation that dates to January 1, 2008, would likely also impose an undue burden. This information will be 20 years old by the time these program revisions go into effect. By comparison, Canada's Clean Fuel Regulation only requires documentation to July 1, 2020.

Moreover, as written, if a feedstock supplier for ethanol production cannot obtain the required certification and that ethanol is transported into California, the default CI score of that ethanol is that of ultra-low sulfur diesel (ULSD). This would penalize the ethanol supplier by increasing the CI 6.61 points from the gasoline value, which would otherwise be the appropriate CI score for fuel ethanol acting as a gasoline substitute. Suppliers would therefore be disincentivized from transporting ethanol into California, and ethanol supply may decrease. Inclusion of ethanol into this provision may significantly limit ethanol supply and, thus, gasoline supply (as diesel does not have this requirement), because there are limited oxygenates on the market that meet CARB's requirements. Therefore, lowering ethanol supply by imposing burdensome new requirements may also constrain the supply of gasoline substitutes and may significantly limit gasoline supply.

If CARB retains these "guardrail" provisions, WSPA recommends the following revisions:

- **Definitions and Scope.** The proposed regulation fails to include important definitions – as identified later in the technical section of this letter – that will be necessary for implementation. 241.6 CARB should clearly define the feedstocks covered by the feedstock sustainability criteria to ensure that certification requirements are narrowly tailored to address soybean oil and canola-based biodiesel and renewable diesel. The proposed amendments do not define crop- and

[20] See 80.1454(c).
[21] See 80.1454(g).
[22] Energy Independence and Security Act, Public Law 110-140 enacted December 19, 2007.

forest-based feedstocks. Without a definition, CARB's proposed tracking and certification requirements may apply to ethanol, which would likely impose significant burdens on alternative fuels that are critically important for achieving California's stringent gasoline formulation requirements.

241.7
- **Certification Process.** CARB should clarify procedures for entities to submit certifications under the proposed requirements. Section 95488.9(g) focuses on requirements for entities seeking to become approved certification systems, but gives little direction to entities complying with the sustainability standards. WSPA requests clarification on the following issues:
  - How and when will certifications be submitted?
  - Which party is responsible for submitting the certification – the feedstock supplier, the fuel pathway holder, or the fuel reporting entity?
  - Can this obligation transfer? The proposed regulation states that fuel quantities reported under fuel pathways utilizing feedstocks not certified by the deadline will be assigned the ULSD CI. However, this does not account for co-processed feedstocks, some of which may have certification and others that do not.

241.8
- **Certification System Approval.** CARB should define clearer criteria for certification scheme approval. Proposed § 95488.9(g)(1)(B)(2) states that the certification system "must consider environmental, social, and economic criteria." However, these criteria are overly vague and leaves too much discretion to the Executive Officer. Instead, CARB should ensure that the approval process includes a mechanism for incorporating input from the public and the regulated industry. This public review process would be more consistent with existing LCFS procedures for pathway applications.

WSPA believes that creating a new crop-based biofuel certification regime by 2028 will be daunting, unjustified, and will only further add to the administrative burden for CARB staff and regulated entities. The proposed LCFS Amendments should provide sufficient time to implement any substantive provisions that directly impact the production and certification of lower CI technologies – including sustainability certifications for crop-based biofuels – as obligated parties must be able to plan accordingly for technology investments and deployment. As such, CARB should defer adding these requirements until a future rulemaking when they can be more thoroughly vetted with stakeholders and address incorporating "climate smart" agricultural practices. If CARB decides to include these certification regimes, WSPA urges CARB to align requirements with programs in other
241.8 jurisdictions, such as Canada's Clean Fuel Regulation, to ensure consistency and to preserve market stability.

Concerns Regarding Proposed Specified Source Feedstock Attestation Requirements
241.9 CARB's proposed attestation requirement is unnecessary. The specified source feedstock attestation requirements would unduly burden fuel producers with no significant benefit as existing regulatory provisions already require review and verification related to the chain of custody. Fuel pathway holders must submit to third party verification evidence of chain of custody for specified source feedstocks as well as provide a RFS separated food waste plan. Imposing additional attestation requirements on top of these existing provisions would significantly add to process workloads.

If these provisions are retained, WSPA requests that CARB clarify procedural obligations associated
241.9 with attestations. *First*, CARB must clearly specify which default emission factors supply chain entities are required to attest against. It is not possible to attest that a step within the supply chain does not meet a pathway CI unless the default emission factors CARB requires pathway holders to utilize are clearly understood by each entity within the supply chain. For example, using the terms "additional processing" is a broad category that fuel producers may interpret differently than CARB. WSPA does not view water removal and basic filtration at the point of collection as additional

processing. But separating out solids, removing soluble impurities, drying the feedstock and filtration using bleaching clay, diatomaceous earth and/or other filter agents may be considered additional processing.

241.9 *Second*, without some limiting factor, every entity within a supply chain could be pulled into attestation requirements. For example, for a used cooking oil supply chain, current provisions could be read to require that each individual restaurant maintain attestations, all the way back to the first collection point. WSPA recommends that CARB specify that attestation requirements begin at the physical feedstock aggregator where feedstocks are collected before any processing occurs upstream of the fuel producer to limit burdens associated with this requirement. This approach would be consistent with the limited attestation language provided in § 95488.8(g)(1)(D)(3), which contains information that only later entities in the supply chain would be able to attest to (specifically, that "the specified source feedstock has not undergone additional processing, such as drying or clean-up except as explicitly included in the pathway life cycle analysis and pathway CI").

241.9 *Third*, CARB should clarify that attestations will not be required to be passed down the supply chain from entity to entity, and that fuel pathway holders will not be liable for failure of supply chain entities to meet the attestation letter requirement. Such a requirement is unnecessary given the existing feedstock supplier auditing requirements, which ensure that both third-party verifiers and CARB have sufficient information to verify compliance. To address these procedural issues, WSPA recommends that CARB provide guidance documents, including examples, for regulated entities, supported by clear regulatory language. CARB already has third-party requirements on specified source feedstocks; however, as indicated above, the verification (or attestation) requirement belongs with the feedstock producer, not with the renewable fuel producer that purchases the feedstock.

Reporting Requirements for Newly Obligated Intrastate Fossil Jet Fuel

The proposed LCFS Amendments would eliminate the existing exemption for intrastate fossil jet fuel and make fuel importers and producers the First Fuel Reporting Entity beginning in 2028. 241.10 WSPA strongly urges CARB to retain the exemption, or make aircraft operators (which include passenger airlines, aircraft cargo companies, and small aircraft owners) the First Fuel Reporting Entity instead, consistent with CARB's earlier proposal in considering program updates.

Fuel importers and producers lack sufficient information to meet these additional reporting requirements. Under the newly proposed reporting requirements, these entities would be required to report information on how fossil jet fuel is *used*, based on whether aircraft operators use fossil jet fuel <u>only</u> for intrastate flights (defined as flights that take off and land in California). Under other existing regulatory provisions, fuel importers and producers generate deficits at the time of importation or production – but CARB would now be imposing the point of deficit generation at end-use, past even the point of sale. It seems unlikely that a fuel importer or producer could manage this obligation. Airport storage facilities are typically jointly owned by the airlines, and the fuel in these storage facilities is not segregated out by airline. After delivery of the fuel into an airport storage facility, fuel importers and producers have no visibility into how individual airlines use the jet fuel. Requiring fuel importers and producers to report on usage would be extremely challenging, if not impossible.

Aircraft operators are far better positioned to report on fuel usage, and can better ensure that the reported information is accurate. Operators possess relevant information to support reporting, including:

- How each individual operators use the fuel supplied to the airport storage facility;
- Which plane the fuel is uploaded into; and

- The flight path of each plane (including those scheduled to take off and land within the State of California).

Some of this information may be considered confidential business information, which WSPA believes should not be shared with fuel producers and importers. The proposed amendments do not specify what information airlines must provide to fuel producers and importers or how information-sharing would work. Without access to this information, fuel suppliers cannot verify end use and cannot meet the proposed reporting obligations.

This information/reporting mismatch creates substantial challenges that extend well beyond logistical concerns:

241.10
- ***Overreporting.*** To account for lack of information on flight paths, fuel importers and producers may need to assume that any fuel delivered to an airport storage facility will be used in-State unless an aircraft operator explicitly states otherwise. Reporting would therefore unwittingly include interstate and international jet fuel, which the program is not intended to regulate. Further, it is unclear if the existing compliance reporting reconciliation timeline fits within any existing data collection process an aircraft operator utilizes to ensure deficits are not accrued for non-obligated uses.

241.10
- ***Increased Prices***. Without information on the intended use of the fuel at the time a transaction takes place, *all* fossil jet fuel may carry an obligation which may increase the price of jet fuels within the State.

241.10 The ripple effect of adding the intrastate jet fuel obligation may include aircraft operators re-optimizing flights to flight paths to include additional fueling outside of California, reducing intrastate jet fuel consumption; this would contribute to emissions leakage. Under Assembly Bill (AB) 32 (2006), CARB has an obligation to minimize leakage resulting from its regulatory activities.

As described above, fuel importers and producers have no ability to differentiate between intrastate, interstate, and international fuel usage in meeting proposed reporting obligations.[23] CARB also has not proposed a definition for intrastate jet fuel consumption, including an appropriate method for calculating the quantity of jet fuel consumed. Airlines have varying approaches to fueling operations, including visiting multiple stops between fueling (e.g., out-of-State, visiting multiple California airports without refueling). As written, CARB's proposal will sweep in a broad range of fueling operations outside intrastate jet fuel consumption and impose significant reporting burdens on entities that have minimal connections to California. CARB's proposal may therefore impermissibly burden *inter*state commerce in violation of the Dormant Commerce Clause doctrine. States cannot
241.11 place burdens on interstate commerce that are "clearly excessive in relation to the putative local benefits."[24] By regulating aviation fuels, CARB's proposal impacts the instrumentalities of interstate transportation and impedes the flow of interstate commerce.

In sum, WSPA believes that the addition of intrastate fossil jet fuel deficits creates unique challenges and may not address the goal of encouraging alternative jet fuel use. If CARB proceeds with this addition, WSPA strongly encourages CARB to reconsider this proposed amendment and return to the proper reporting parties that *do* possess the knowledge required to accurately comply: the aircraft operators. CARB must also incorporate better definitions and clear compliance methodology, including the following:

---

[23] Interestingly, there is no consideration that some fossil jet fuel imported or produced in California may also be used in military applications. There is no evaluation of whether this is a legally permissible scope for LCFS or whether fuel producers and importers could reasonably expect to be provided with information about the end use of such fuel, given the classified nature of such information.
[24] *Pike v. Bruce Church, Inc.*, 397 U.S. 137, 142 (1970).

- The First Fuel Reporting Entity for intrastate fossil jet fuel use would be the aircraft operators (or Fixed Base Operator for general aviation use).

241.10
- A simplified reporting approach that does not rely on aircraft operators to track and report actual consumption. CARB should work with aircraft operators to determine a mileage-based multiplier or similar methodology.
- Clear verification parameters specific to intrastate jet fuel reporting.

LCFS Program Stringency

CARB is proposing several updates to increase the LCFS program stringency. *First*, the amendments would set more stringent CI reduction targets, increasing the 2025 CI target by 5%, increasing the 2030 CI reduction target from 20% to 30%, and adding a 2045 CI target of 90%. *Second*, the proposed amendments would add a triggering mechanism – the Automatic Acceleration Mechanism (AAM) – which would advance the CI standard in a given year to a future year if specified market conditions are met, in order to bridge periods of credit surplus and maintain a steadier program signal.

The proposed amendments increase program stringency while removing certain compliance tools and key flexibilities for fuel producers that mitigate program costs. Based on this confluence of factors, without certain protections in place, the AAM may compromise necessary market signals that incentivize the production of lower-CI fuels while preserving consumer choice and providing a
241.12 level playing field for all technologies. To better understand potential market impacts, WSPA requests that CARB release information on how often the AAM could be triggered, using the modeling scenarios CARB developed with the CATS Model. In addition, we recommend that CARB incorporates a robust yearly review as a standard program feature to evaluate the impacts of these
241.12 structural changes, including the annual status of the credit bank, and the effects on California energy prices. Energy pricing data is readily available, since LCFS-associated costs embedded into all wholesale gasoline sales are required to be reported on a monthly basis pursuant to SB 1322 and SB X1-2.[25] CARB should also incorporate a robust consultation process with relevant stakeholders (such as fuel providers and distributors) to better understand potential issues and
241.12 consider possible unintended consequences during this annual review and before triggering the AAM.

In order to address any credits-to-deficit imbalance resulting from overly aggressive CI benchmarks
241.13 or the AAM, CARB should also incorporate a reset mechanism. This mechanism would strengthen the credit trading market by providing greater regulatory certainty and strike an appropriate balance between achieving meaningful reductions offering sufficient business, technology, and financial support to industry, which would ensure these accelerated targets are durable and achievable. Such a mechanism should be available in several circumstances tied to market activity signals and statutory factors, including: a recession or an accelerated growth period in California, a significant unforeseen event (e.g., a global pandemic), and growing affordability and supply reliability issues. Incorporating a reset mechanism would better effectuate SB X1-2's directive for State agencies to evaluate measures to ensure that petroleum and alternative transportation fuels are adequate, affordable, reliable, and equitable, and would better fulfill CARB's duty under HSC § 38560 to ensure that its regulations are cost-effective. Consistent with SB X1-2, CARB must consider impacts to gasoline costs resulting from its regulations, including the LCFS program and other programs such as the Cap-and-Trade program. As the SRIA indicates that LCFS pass-through costs on gasoline will be well over $1.00 per gallon beginning in 2037,[26] CARB must mitigate additional costs in adopting LCFS program updates.

---

[26] CARB LCFS 2023 Amendments SRIA, September 8, 2023, Table 22 at https://dof.ca.gov/wp-content/uploads/sites/352/2023/09/LCFS-SRIA-to-DOF-ADA-Compliant.pdf

Program Streamlining Recommendations

WSPA appreciates CARB's ongoing efforts to streamline program implementation by updating existing Tier 1 calculators and creating a new Tier 1 calculator for hydrogen. WSPA encourages CARB to build on these efforts and address additional inefficiencies associated with the current
241.14 pathway application review and approval process (for registration and renewals). The current system includes duplicative steps that increase workloads for both CARB staff and pathway applicants. To address these redundancies, CARB should work directly with regulated entities, who have significant experience navigating the application process and can readily identify improvement opportunities.

There are currently informal policies and processes in place that would benefit from formal direction via regulation. For example, for both Tier 1 and Tier 2 fuel pathway applications, CARB should
241.14 streamline the fuel pathway application process when an applicant submits a fuel pathway that adds a new feedstock for an existing renewable fuel facility. In such case, CARB should allow the submission under the same fuel pathway application number as the original fuel pathway application, possibly with the original application number with a revision number (e.g., B0123-02). The review process by both CARB and the third-party should also be expedited and focus on the new feedstock. No site visit by the third-party verifier should be required. The Annual Fuel Pathway Report (AFPR) process would also be simplified by submitting a single AFPR for a renewable fuel facility that processes multiple feedstocks, rather than submitting a duplicated AFPR as is currently required.

WSPA urges CARB to adopt the following administrative improvements to streamline the program:

- ***Pathway Holder Deficit Obligation.*** CARB should lessen deficit obligations for pathway holders
241.15 that exceed their CI in a 24-month period. Under the proposed amendments, pathway holders would incur a deficit four times the amount of the annual excess CI generated, *and* have excess credits invalidated, which effectively creates a penalty of five times the amount of the annual excess CI generated. This penalty is disproportionate to the severity of the violation and will likely have an outsized impact on pathway holders, particularly since any true up benefit in a CI is provided to the *importer*, not the pathway holder. Both the benefit *and the obligation* should be with the same party. CARB should lessen the severity of this obligation and either (1) impose the deficit on the importer, or (2) provide true up benefits to the pathway holder as well. Imposing deficit obligations on pathway holders who do not produce fuel in the State, import fuel into the State, or sell fuel into the State, may also unduly burden interstate commerce in violation of the Commerce Clause, by requiring out-of-State pathway holders to suddenly participate in the credit/deficit market, which creates significant new obligations compared to being a pathway holder participant. WSPA also requests clarity on when fuel pathway holders would need to register in the LCFS Reporting Tool and Credit Bank & Transfer System (LRT/CBTS) and when they would become subject to the reporting requirements in § 95491.
- ***Expiring Fuel Pathways.*** Consistent with WSPA's prior comment letters, WSPA urges CARB
241.16 to keep pathway codes active for two quarters after their expiration date. Under the current LCFS Regulation, regulated entities can sell volumes up to two quarters after purchasing them. CARB should keep these pathway codes active for two quarters after their expiration date, to allow for follow-on downstream activity to be reported. Any new production would not be allowed to be reported during those two quarters. This would eliminate a substantial amount of ongoing rework when downstream parties report a legitimate resale of a pathway purchased, only to find later that CARB has deactivated it.
- ***Accelerate Approvals Where Feasible.*** CARB should accelerate temporary pathway approvals or provisional pathway approvals by creating a 30-day deadline to review a temporary
241.17 fuel pathway request application and provide initial feedback. CARB is proposing to change the "deemed complete date" for Tier 2 applications; however, this date does little to streamline the

pathway application process or resolve the issues with fuel pathway processing, given that application reviews and validations are taking several months to complete. This means that credit generation is delayed while these reviews are ongoing. Ultimately, availability of the certified pathway often occurs multiple quarters, if not years, after the deemed complete date. Rather than merely deeming an application complete, the application should be automatically deemed complete *and approved* if CARB staff has not reviewed the application within 30 calendar days. CARB should also consider automatically extending temporary pathways for pathway applicants who have a Tier 1 or Tier 2 pathway application pending. Finally, WSPA notes that it is critically important that CARB ensure there are adequate resources to support the development and implementation of an efficient fuel pathway review process.

241.18
- ***Credit True Ups***. CARB should revise the proposed regulatory language to specify that CARB "shall" perform a credit true up for a fuel pathway. As drafted, the current language states only that CARB "may" perform a credit true up for a fuel pathway, which creates uncertainty. WSPA also urges CARB to include credit true ups back to a facility's startup date and the approval of both temporary and provisional pathways from startup of renewable fuel production.[27]

241.19
- ***Verifications***. WSPA encourages CARB to extend the proposed provisions allowing for "less intensive" verifications for entities that receive a positive verification result to other fuel suppliers and projects in order to reduce administrative burdens. In addition, WSPA urges CARB to limit site visit requirements for third-party verification. CARB should allow third-party verification site visits to be done remotely. Video conferencing and screen sharing are well-established technologies and should be sufficient for other types of verification, especially the verification of LCFS quarterly reports. CARB should also limit site visit requirements to an initial LCFS fuel pathway validation, and once every three years thereafter for LCFS fuel pathway verification. Lastly, CARB should work to incorporate a thorough evaluation process for new or converted facilities, followed by a more streamlined process for such sites for future reviews as part of one application process.

241.20
- ***Incremental Deficits***. CARB should streamline crude CI determinations by eliminating the annual update requirement. Under the current program, CARB updates the Oil Production Greenhouse Gas Emission Estimator (OPGEE) Model and determines the average crude CI on an annual basis, which requires reporting entities to expend significant time and resources generating MCON reports and having the MCON reports verified by third parties. Compared to this significant effort, annual adjustments to the CARBOB and ULSD CI score have been very minor. Instead, reducing benchmarks has a comparatively outsized impact on deficit generation. WSPA recommends that CARB address any significant impacts on the crude CI to CARBOB and ULSD during the LCFS rulemaking process instead of requiring annual updates.

241.21
- ***MCON (Crude) Reporting***. CARB should eliminate the requirement for refineries to report California crudes by field name in the MCON report. This reporting requirement is unnecessary, because CARB is using data from the California Department of Conservation instead. CARB should also eliminate verification requirements for California crudes.

241.22
- ***Information Technology (IT) Updates***. WSPA recommends including an IT portal system that allows many separate entities to input their own CI data to generate a "create your own pathway score" tool. For example, if an entity wants to process feedstock through crushers and refiners (that are already in the system), the entity would be able to just allocate volumes across a refinery/crusher using the database.

[27] See Section 95488.10(a)(1).

241.23
- ***Enhanced Communication.*** CARB should provide regular status updates on temporary pathway applications that can be shared with counterparties. CARB should post a list of approved temporary pathways by company and by date of applicability.

241.24
- ***Reporting Deadlines.*** CARB should change the third quarter reporting deadline from December 31st to January 15th, to allow flexibility over the winter holidays.

241.25
- ***Crediting for Corrected Reporting Errors.*** CARB should allow credits to be generated for reporting errors that have been corrected. Corrections for commercial transactions and accounting adjustments are a routine part of business and regulated parties should not be penalized for improving the accuracy of reporting under the LCFS program.

241.26
- ***Abnormalities.*** WSPA recommends that CARB provide guidelines to account for transient operations and abnormal conditions given the 24-month data requirement.

241.27
- ***Implementation of GREET 4.0.*** To maintain consistency in the program and minimize disruption, current pathways should remain open during the transition from GREET 3.0 to GREET 4.0. Please see further comments below regarding specific GREET 4.0-related issues and concerns.

Limiting Hydrogen Unnecessarily Constrains Investment and Deployment Opportunities
Incentivizing growth and investment in the hydrogen sector is critical for California's efforts to reduce GHG emissions while also providing affordable, reliable, and cleaner energy for all Californians. According to CARB's 2022 Scoping Plan Update[28] the State will need to add approximately 1,700 times the amount of the current hydrogen supply by 2045. Scaling up hydrogen production for California's energy systems requires development of a broad range of technologies, including steam methane reforming (SMR), autothermal reforming (ATR), and electrolysis using renewable electricity, as well as biogas, biomethane, and thermochemical conversion of biomass and waste feedstocks.[29]

241.28
Yet CARB's proposed program updates would inhibit hydrogen development by imposing new constraints on hydrogen eligibility within the LCFS program. Specifically, CARB should not propose to limit end-uses of program-incentivized hydrogen based on a "color" system, limit Book-and-Claim accounting for hydrogen, and impose a new 50% capacity cap. CARB should reconsider these proposals.

241.28
- ***Hydrogen End-Uses.*** Limiting end-uses of program-incentivized hydrogen will inhibit the development of additional hydrogen production. Instead, the LCFS program should continue to preserve consumer choice and provide a level playing field for all technologies, embracing fuel- and technology-neutral principles that focus on the meaningful and timely reduction of GHG emissions. WSPA urges CARB to adopt a technology-neutral approach that uses a CI score as the main driver to reduce emissions, rather than a "color" system that constrains uses. The color system creates regulatory uncertainty by facilitating subjective, changing definitions and interpretations of permissible uses, which stifles long-term investment and innovation.

  CARB assumes that limiting end-uses of hydrogen will funnel new capital investments to certain preferred hydrogen technologies such as electrolysis using renewables, a technology that is, by most estimates,[30] at least triple the cost of hydrogen currently produced by SMR.

[28] 2022 Scoping Plan Update https://ww2.arb.ca.gov/our-work/programs/ab-32-climate-change-scoping-plan/2022-scoping-plan-documents

[29] *See* CEC, "Roadmap for the Deployment and Buildout of Renewable Hydrogen Production Plants in California," June 2020. https://www.energy.ca.gov/publications/2020/roadmap-deployment-and-buildout-renewable-hydrogen-production-plants-california

[30] Justin Bracci, Adam Brandt, Sally M. Benson, Gireesh Shrimali and Sarah D. Saltzer, "Pathways to Carbon Neutrality in California: The

However, rapid growth across a broad range of hydrogen technologies must be incentivized to successfully scale up hydrogen production. Large-scale innovation and new investment in various industrial sectors relies on a diverse portfolio of resources. Arbitrarily restricting end-uses will stifle investments and innovation, and conflict with federal funding incentives.

By constraining end uses, CARB is failing to achieve the "maximum technologically feasible and cost-effective greenhouse gas emission reductions" in accordance with Health and Safety Code § 38560. A technology-neutral approach would better align with CARB's rulemaking obligations under Government Code § 11346.2(b)(4)(A), which requires CARB to consider performance standards as an alternative to mandating the use of specific technologies or equipment, or prescribing specific actions or procedures.

- ***Book-and-Claim Accounting***. The proposed regulatory updates would unnecessarily limit Book-and-Claim Accounting for hydrogen, which would likely constrain growth in hydrogen production and deployment. This conflicts with emission reduction measures in the 2022 Scoping Plan Update, which requires significant expansion of hydrogen production. As noted in WSPA's prior comment letters, the goal of the LCFS program is to incentivize the production of low carbon intensity fuels and energy sources for transportation, rather than fuel/energy dispensing infrastructure. All hydrogen production pathways should be considered based on
241.28 their CI reduction potential. CI benchmarks should be used as the singular determining factor to drive CI reductions and credit values.

- ***Capacity Cap.*** CARB is proposing a new 50% capacity cap to incentivize more market participation without inflating the overall credit supply. However, this approach may instead nullify investor incentives and constrain future hydrogen development. A capacity cap is
241.29 unnecessary – the LCFS program already includes a 2.5% limit on credits, and this segment has not yet come close to reaching the limit.

- ***Tax Credits***. CARB is proposing to model LCFS program updates on pending federal updates to tax credits under Internal Revenue Code Sections 45V and 48(a)(15). Imposing well-to-wheel CI limits of ≤55 grams per megajoule (gCO2e/MJ) for gaseous hydrogen and ≤95 gCO2e/MJ for liquid hydrogen for pipeline transfers to "align" with the US Treasury/IRS proposed rule on Section 45V "Clean Hydrogen Production Tax Credit" of the Inflation Reduction Act, is unnecessary and confusing. The Treasury/Internal Revenue Service (IRS) proposal was published on December 26, 2023, and will likely be finalized well after CARB finalizes these LCFS amendments. These regulations may significantly change before they
241.30 become final. However, if CARB seeks to align these programs, then it should, at minimum, retain the IRS's technology-neutral approach.

SPECIFIC COMMENTS

Section 95481. Definitions and Acronyms

The proposed regulation is missing critical definitions that will make implementation challenging for CARB and regulated entities. This includes a definition for crop- and forest-based feedstocks as
241.31 well as palm derivatives. For example, CARB is proposing to prohibit transportation fuels produced from palm oil or palm derivatives, based on deforestation concerns identified by the European Commission.[31] However, without a clear definition of "palm derivatives," this action may exclude

---

Hydrogen Opportunity," Stanford Center for Carbon Storage and Stanford Carbon Removal Initiative.https://sccs.stanford.edu/california-projects/pathways-carbon-neutrality-california.

[31] European Commission, Report from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions on the status of production expansion of relevant food and feed crops worldwide. Brussels. March 13, 2019. https://eur-lex.europa.eu/legalcontent/EN/TXT/?uri=CELEX:52019DC0142 European Commission, Annexes to the Report from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee

fuels that can contribute to the objectives of the LCFS program, such as fuels derived from palm oil mill effluent (POME) oil, waste oil extracted from spent bleaching earth from palm oil refining (SBEO) or empty palm fruit bunches oil. These fuels are different from palm oil and are not considered high-risk feedstock. The European Union's REDII Annex IX Part A[32] considers waste generated by palm oil mills, such as POME oil, SBEO[33] and empty palm fruit bunches oil, as "advanced" raw materials. The European Union has also distinguished between the *types* of palm derivatives, including POME oil, SBEO, empty palm fruit bunches oil, and palm fatty acid distillates (PFAD). PFAD are excluded from the residue definition in European jurisdictions (e.g., Germany, Sweden, Norway), while POME oil and empty palm fruit bunches oil are included in the REDII as waste streams within either energy intensity or GHG reductions. These alternative fuels can significantly reduce GHG emissions – the International Council on Clean Transportation (ICCT) has indicated that renewable diesel derived from POME oil has a net GHG emission reduction of 71%.[34] CARB should narrowly define any restrictions for "palm derivatives" to facilitate feedstocks such as POME oil, SBEO and empty palm fruit bunches that can contribute to the stringent carbon intensity reductions contemplated in the proposed rule. CARB should also ensure that the scope of the certification requirements are clearly defined – the proposed amendments do not define "point-of-origin," which creates significant uncertainty on the point of certification requirement.

Other considerations in proposed definitions and acronyms include:

241.32
- *"Alternative Jet Fuel" means a drop-in fuel made from ~~petroleum or~~ non-petroleum sources, which can be blended ~~and used with~~ <u>into</u> conventional ~~petroleum~~ jet fuels without the need to modify aircraft engines and existing fuel distribution infrastructure."*
  - This amendment, to eliminate petroleum sources, would eliminate coprocessing and other means to produce Sustainable Aviation Fuel. CARB should remove the proposed strikeouts and restore the original wording.

241.33
- *"Break ground" means earthmoving and site preparation necessary for construction of the digestor system and supporting infrastructure that starts following approval of all necessary entitlements/permits for the project."*
  - This definition should be expanded to other projects. It should not singularly apply to digestor systems.

241.44
- *"Byproduct" means a secondary product with marginal economic value outside its use in a biofuel pathway.*
  - WSPA seeks clarification from CARB that a "byproduct" cannot be designated as a co-product.

241.45
- *"Clean Fuel Reward" is a statewide program established by EDUs to provide a reduction in price ~~on new light duty EV~~ purchases or leases for new medium- or heavy-duty electric vehicles that are not subject to the High Priority and Federal Fleets requirements as specified in, title 13, California code of Regulations, section 2015(a)(1) in California. The Clean Fuel Reward is funded exclusively through LCFS proceeds generated by EDUs from electricity fuel.*
  - WSPA requests that CARB confirms that the intent of this definitional change is to no longer generate Clean Fuel Rewards for light duty vehicles.

241.46
- *"Conservative" means reducing the estimated GHG reduction benefits of an operation or utilizing methods and factors that over-estimate energy usage or carbon intensity (90th*

of the Regions on the status of production expansion of relevant food and feed crops worldwide. Annexes 1 to 2. Brussels. March 13, 2019. Searle, S., Defining Low and High Indirect Land-Use Change Biofuels in European Union Policy. The International Council on Clean Transportation. November 2018.

[32] Directive (EU) 2018/2001 of the European Parliament and of the Council of 11 December 2018 on the promotion of the use of energy from renewable sources. Source: https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=uriserv:OJ.L_.2018.328.01.0082.01.ENG&toc=OJ:L:2018:328:TOC

[33] See Annex 9A under part (g), Commission Implementing Regulation (EU) 2022/996, June 14, 2022, on rules to verify sustainability and greenhouse gas emissions saving criteria and low indirect land-use change-risk criteria.

[34] "Potential greenhouse gas savings from a 2030 greenhouse gas reduction target with indirect emissions accounting for the European Union.

241.46 *percentile or highest value) or under-estimate produced fuel volumes (10th percentile or lowest value).*

- WSPA requests that CARB clarify this definition because under-estimating produced fuel volumes of CARBOB or ULSD is *not* a "conservative" estimate.

241.47
- *"Organic Waste" is material that meets both the LCFS definitions of "biomass" and "waste."*
  - WPSA requests that CARB provides some examples of what qualifies for organic waste and what does not.

241.48
- *"Renewable Naphtha" means naphtha that is produced from hydrotreated lipids and biocrudes, or from gasified biomass that is converted to liquids using the Fischer-Tropsch process. This includes the renewable portion of a naphtha fuel derived from co-processing biomass with a petroleum feedstock.*
  - CARB should extend the definition of renewable naphtha to any type of renewable feedstocks.

<u>Section 95482. Fuels Subject to Regulation</u>

241.49
- In (a)(11) CARB should remove fossil jet fuel. Otherwise, CARB should specify "intrastate" fossil jet fuel.
- In (c)(2) CARB should clarify by stating: Fossil jet fuel. Otherwise, CARB should specify "Fossil jet fuel produced or imported before 2028 or used for interstate or international flights <u>in any year</u>."

241.50
- In (f), CARB should confirm that this section does not apply to fuels such as used cooking oil from palm oil, and therefore used cooking oil from palm oil is eligible for LCFS credits. Please refer to comments above on palm derivatives definitions.

<u>Section 95483. Fuel Reporting Entities – Jet Fuel</u>

241.10
- In (a), the reference to "fossil jet" should be removed from this section. In (a)(C), the reference to "fossil jet" should be removed from this section as well.

<u>Section 95484. Annual Compliance Benchmark</u>

241.51
- <u>In (b), Auto-acceleration Mechanism,</u> (2) CARB needs to clarify the definition of $Credits_{20xx}$ and $Deficits_{20xx}$: does $Credits_{20xx}$ represent the cumulative total number of credits generated since 2011 ("the program") or does it represent the number of credits generated in a single year? Does $Deficits_{20xx}$ represent the cumulative total number of deficits generated since 2011 ("the program") or does it represent the number of deficits generated in a single year? WSPA requests that CARB explain the basis for the equation under 95484(2)(A). WSPA recommends that CARB conducts a formal annual program review which would consider not only historical data, such as the credit bank and the deficits and credits generated, but also a forecast of the fuel demand and production in the various category of fuels. This information would be used to assess how the benchmark would be set (higher, flat, lower) for the next compliance period(s). This would be more practical that borrowing credits from the future as described in section 95485 (c)(3)(C) (Advanced Credits).

241.52
- WSPA requests that CARB justify why the USLD baseline values increase by more than 5 gCO2e/MJ starting in year 2025 at 105.76 gCO2e/MJ from 100.45 gCO2e/MJ in the current regulation.

<u>Section 95485. Demonstrating Compliance</u>

241.53
- In subsection (c)(3)(c) Advanced Credits, WSPA appreciates that CARB is proposing to increase the limit of Advanced Credits from 10 to 30 million. However, as described in our other comments regarding benchmarks, it would be more effective if CARB "froze" the benchmarks instead of advancing credits from the future as described in this section.

Section 95486.1. Generating and Calculating Credits and Deficits Using Fuel Pathways

241.54
- In Section 95486.1, under deficit obligation for verified CI exceedance, the nature of a facility's operations will result in variation of CI with time, which could result in unintended situations where the certified CI is exceeded. To account for these operational variations, similar to the provision for the incremental deficit calculation associated with crude, CARB should consider only accounting for true ups (deficits or credits) when the difference exceeds a certain threshold.

241.55
- In (a)(1), CARB should remove the reference to fossil jet fuel.

241.56
- In (g) and (g)(1), Calculation of Deficit Obligation for Verified CI Exceedance, CARB should not apply a penalty of four to five times (when including the penalty for the pathway holder as a first reporter) the deficits if the fuel pathway CI is higher. This is excessive. CARB should apply one times the deficit and reset the CI score to the verified value and allow for rebalancing and readjustments by affected parties.

Section 95488.5. Lookup Table 7-1

241.57
- CARB should justify the significantly higher CI score for ULSD compared to the current rulemaking (105.76 vs. 100.45 gCO2e/MJ).

Section 95488.6. Tier 1 Fuel Pathway Application Requirements and Certification Process

241.14
- In section (b)(2)(A), the deemed completed date should remain when CARB approved the submission, *before* the fuel pathway application is routed to the third-party verifier. Otherwise, the fuel pathway applicant will likely need to report for an extra quarter with the temporary CI score.

Section 95488.7. Tier 2 Fuel Pathway Application Requirements and Certification Process

241.58
- In section (d)(3): The deemed completed date should remain when CARB approved the submission, *before* the fuel pathway application is routed to the third-party verifier. Otherwise, the fuel pathway applicant will likely need to report for an extra quarter with the temporary CI score.

Section 95488.8. Fuel Pathway Application Requirements Applying to All Classifications

241.9
- In section (g)(1)(D), WSPA requests more detail on how the feedstock producers should be responsible for the attestation letter, if CARB maintains this new requirement, and what at what frequency the attestation letter needs to be renewed.

241.28
- In section (i), CARB should allow book-and-claim accounting for low-CI electricity, biomethane, and low-CI hydrogen for the production of renewable fuels as well, such as the production of renewable diesel.

Section 95488.9(b). Special Circumstances for Fuel Pathway Applications

241.59 For Temporary CI Scores (Table 8), CARB should explain and justify why it proposes to increase the CI scores of the temporary pathways by 5 gCO2e/MJ for biodiesel and renewable diesel.

Section 95489. Provisions for Petroleum-Based Fuels

241.60
- In section (a), incremental deficit calculation for crude oil, WSPA notes that the equations for the baseline crude averages appear to be incorrect. Appendix E of the ISOR states that the equations for the three-year California Crude Average CI and California Baseline Crude Average CI contained in this section are being revised "*to be consistent with the updated Oil Production Greenhouse Gas Emission Estimator (OPGEE) model version, the updated Carbon Intensity Lookup Table for Crude Oil Production and Transport, and the implementation timeline of the amended regulation*." However, it appears that the existing CI factors continued to be used in the $CI_{BaselineCrudeaAve}$ calculations. These CI factors should be updated to reflect the revised factors derived using OPGEE 3.0b (which are assumed to be the updated factors

listed in the updated Table 9).

- In section (a), fossil jet fuel and deficit calculation, CARB also proposes to add the following language to the E^{xd} parameter: "*For fossil jet fuel (XD = "fossil jet fuel"), E^{XD} is either produced in California or imported into California during a specific calendar year starting in 2028 and sold, supplied, or offered for sale in California*." As drafted, this language would capture both intrastate and *inter*state jet fuel, which is expressly beyond the scope of CARB's proposal. The
241.61 added language should be revised to clearly state that the parameter should only include intrastate fossil jet fuel.
- 241.62 In section (e)(1)(G), CARB should maintain the eligibility criteria for a project that generates at least 10,000 credits not to discourage GHG reduction projects.
- 241.63 In section (e)(5)(B), CARB should not arbitrarily disallow refinery investment credits after 2040. The LCFS standards will be very stringent then and will need many crediting sources.
- 241.64 In section (f)(5)(B), CARB should not arbitrarily disallow renewable hydrogen refinery credits after 2040. The LCFS standards will be very stringent then and will need many crediting sources.

Section 95491. Fuel Transactions and Compliance Reporting

- 241.24 In section (b)(2) and table 12, CARB should change the third quarter reporting deadline as January 15, as the current deadline of December 31 is conflicting with holiday vacations.

GREET 4.0 Update Issues and Concerns

- **Modifications Incorporated in CA-GREET 4.0.**
  - A backhaul energy intensity was added to ocean tanker transport for Brazilian sugarcane. Though Appendix B indicates that this is based on data provided by fuel suppliers, this does not apply to all fuel suppliers. WSPA requests that pathways should determine whether a backhaul is included and verify it as part of the verification process. Additionally, barges and tugboats that move them within California waters since the passage of the 2022 Commercial
241.65 Harbor Craft (CHC) Regulation are utilizing renewable diesel. The CO2 potion of the emissions from the CHC should not be counted as part of the emission factor for the use of barges in GREET. Like backhaul, pathway holders should be able to petition CARB to reduce emissions from the use of barges within California water as part of the verification process.
  - **Density and Carbon Content Inputs.** From CA-GREET3.0 to CA-GREET4.0, the density and percent carbon content in fuels changed with updates from GREET2016 to GREET2022. The fuel low heating value (LHV) has also been updated separately in CA-GREET4.0 to match the LRT-CBTS reporting system. These data points are then used to determine the tailpipe CO2 emissions of various fuels. For California diesel, the changes result in a ~2 g/MJ increase of the baselines default values. We are uncertain of whether the combination of LHV and density/percent carbon content reported in CA-GREET4.0 are
241.65 accurate as they are obtained from different sources. The LHV is dependent on the density and percent carbon content of the fuel and therefore, CARB should be using a consistent basis when updating the values.
  - **Tailpipe Emission Factors.** It appears that CARB updated GREET2022 transportation and tailpipe emission factors with data from the EMFAC2021 (v1.0.2) model, which reflects significant changes in ULSD tailpipe nitrous oxide (N2O) emissions, from 0.724 g/MJ in CA-CA-GREET3.0 to 3.49 g/MJ in CA-GREET4.0. However, it seems tailpipe N2O emissions for lower emission fuel pathways, such as biodiesel and renewable diesel, are based on a different data source and consistent with the CA-GREET3.0 data. We request that CARB
241.65 explain this choice as CARB should treat all fuels under a consistent framework for model input and output accuracy.

  - **Natural Gas.** CARB should update the methane fugitive factors by using GREET 2022, not the obsolete factors from GREET 2014.
  - **Tallow energy use.** CARB should update the tallow energy use with the data from GREET 2022, not the obsolete value from GREET 2016.

- **Expirations.** WSPA is concerned with any potential of pathways that were developed under CA-GREET 3.0 expiring as CARB transitions to CA-GREET 4.0. To maintain consistency in the
241.66 program and minimize disruptions, current pathways should remain open during the transition from GREET 3.0 to GREET 4.0.

241.67 - **Data Assumptions.** WSPA requests that CARB provide data sources used to update electricity transmission and distribution losses in the model.

WSPA appreciates the opportunity to provide comments. If you have any questions regarding this submittal, please contact me via email at tderivi@wspa.org.

Sincerely,

Dr. Cheryl Laskowski
Branch Chief – Low Carbon Fuel Standard
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: WSPA Comments on CARB Workshop to Discuss Potential Changes to the LCFS

Dear Dr. Laskowski,

Western States Petroleum Association (WSPA) appreciates the opportunity to comment on the staff presentation at California Air Resources Board (CARB) Workshop to discuss potential changes to the Low Carbon Fuel Standard (LCFS) held on July 7, 2022. WSPA is a trade association that represents companies that provide diverse sources of transportation energy throughout the west, including California. This includes the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies.

Provided below is WSPA's initial feedback on CARB's proposed changes in the LCFS Program as presented to stakeholders by CARB staff on July 7, 2022:

LCFS is a Critical Part of California's Climate Portfolio - The last bullet point on Slide 9 of the CARB staff presentation states: *"Providing long-term price signals needed to support transition to ZEVs and decarbonizing remaining liquid fuel demand."* The LCFS program should remain fuel/energy carrier neutral and not privilege ZEV technology to the detriment of liquid or gaseous fuels. The carbon intensity (CI) is the referee in the LCFS program, so if a liquid or gaseous fuel with low CI values can compete with ZEV technology, CARB should ensure these technologies remain available in the program and are treated fairly, as enablers of carbon reductions.

Accelerating 2030 Target to 25% or 30% - The CARB staff presentation (Slide 12) introduced a proposal to potentially accelerate the LCFS (CI) reduction targets to 25% or 30% by 2030. WSPA is concerned that this proposal has been presented to stakeholders without the illustrative compliance scenarios necessary to demonstrate potential pathways to achieving these targets. WSPA encourages CARB to hold a series of workshops focused on this topic and direct engagement with stakeholders as soon as possible. The illustrative compliance scenarios should, at minimum, include an assessment of the demand for low CI fuels among the western states and Canada as multiple low carbon fuel programs drive competition.

Post-2030 CI Targets - While setting aspirational long-term targets can be a signal to encourage investment in low-carbon alternatives, these targets would be arbitrary and established without sufficient underlying analysis and thus are unlikely to be effective. It is also important to note that the Scoping Plan already serves to provide direction for programs like the LCFS. As one of the key elements for a successful Scoping Plan, the LCFS should be focused on nearer-term goals that are supported by peer-reviewed analysis and proven technologies.

WSPA recommends that CARB set LCFS targets no further out than 2030 and consider setting targets for years that are currently more than 10 years out with the next rulemaking.

Market Signals versus Market Disruptions - CARB has built the LCFS program with an intent to provide a market signal for investment. WSPA member companies are working to support California's policy goals and reduce emissions in the transportation sector. WSPA is concerned about the broader impact of CARB's proposal to remove forklifts as a credit generator. This proposal tells regulated entities CARB is reviewing and determining which technologies are in or out of the program based on the metric of "maturity" without discussing the criteria it used to make this assessment. In 2015 when CARB brought into the LCFS the forklift crediting provision it did so with no expiration, subsequent credit provisions bolted onto the program have included expirations and limits that signal CARB's intent to monitor the adoption rates and perceived maturity of a technology. By introducing the concept that a credit provision can simply be stripped from the program creates a disruption. A logical follow up question is "what comes next?" WSPA opposes the concept of using an arbitrary term like "maturation" in the LCFS program, without any discussion on the criteria used to determine if a technology is mature.

MHD HRI/FCI Crediting - For both hydrogen refueling infrastructure (HRI) and fast charging infrastructure (FCI) crediting, WSPA encourages CARB to pursue a practical approach to calculating refueling facility capacities. It was suggested by CARB staff during the workshop that infrastructure credits would be assessed separately for light duty (LD) vehicles and medium/heavy duty (MHD) vehicles. CARB staff's current methodology for applying this distinction is to require separate infrastructure at each fueling location, meaning separate storage, piping, and dispensers for each vehicle type. This is an impractical, inefficient use of resources that will discourage facility expansion. If infrastructure credits are to be a part of the LCFS, they should be applied equitably and efficiently. WSPA urges CARB to work with stakeholders to find a practical solution for assessing the capacity of facilities serving both LD and MHD vehicles.

Arbitrary Pathway Caps - WSPA opposes arbitrary caps on fuel pathways. An example is crop-based biofuel. While we share CARB's concern for food security and any unintended consequences from low carbon fuel programs, a compelling case has not been presented for this proposal. Setting such limits requires a thorough, independent analysis that demonstrates a measurable impact to land use due to crop-based feedstocks used for fuel production. WSPA encourages CARB to continue prioritizing sustainability as part of the LCFS, but objects to any further limitations. CARB already establishes indirect land use change (ILUC) values for crop-based biofuels which is in addition to the production and transportation emissions that together makes up the CI value of the renewable fuel produced from crop-based feedstocks. Therefore, CARB should not create an additional penalty or set an arbitrary limit on the volume of crop-based feedstocks in the program. CARB should work to incentivize the production and use of feedstocks produced sustainably, not limit one of the most important and effective tools CARB has to reduce emissions from the transportation sector.

Pathway Approvals - WSPA believes that the current pathway application review process has inefficiencies that are cumbersome in workload burden to both CARB staff and pathway applicants. A significant restructuring of the process is recommended with input from regulated parties. At minimum, enhancements may include credit true-ups back to a facility's startup date and the approval of provisional pathways from startup of the renewable fuel production. WSPA requests that CARB adds in the LCFS regulatory language a deadline for CARB staff to review a pathway application. If CARB has not reviewed the pathway application within 60 days, the pathway application shall be deemed complete and opened for third-party verification.

Renewable Hydrogen Definition - WSPA believes that all renewable light hydrocarbons, not only biomethane and renewable natural gas (RNG), should have the same consideration as RNG in the LCFS regulation, including for the production of hydrogen. Renewable feedstocks should not be limited to pipeline quality biomethane and RNG in the production of renewable hydrogen. As such, facilities that produce both renewable fuels and hydrogen will utilize internally produced fuels like renewable ethane, renewable propane, renewable butanes, renewable pentanes, and renewable C6+ as feedstocks to produce hydrogen and should qualify for the production of renewable hydrogen. WSPA requests that the definition of renewable hydrogen be expanded to include the use of renewable light hydrocarbons for the production of renewable hydrogen. In addition, renewable hydrogen produced from renewable light hydrocarbons should qualify under the Hydrogen Refueling Infrastructure provision of the regulation for lower emission factors than hydrogen produced from fossil natural gas. The provisions above should apply regardless of whether the renewable feedstocks used to produce renewable light hydrocarbons are waste oils, fats, used cooking oil, distiller's corn oil or "fresh" vegetable oils, such as soybean or canola oils.

Verification - With verifications nearing completion for the second year under the LCFS, CARB should engage regulated parties and verifiers to seek feedback on the process and identify opportunities for improvement.

Aviation Fuel - WSPA would appreciate seeing more details regarding the proposal to obligate intrastate fossil jet fuel (i.e., where the point of obligation would be and how it would be executed). In general, WSPA believes that CARB cannot obligate jet fuel used for intrastate flights.

Much of the aviation industry is inherently interstate and international, making this sector particularly appropriate for the federal government to regulate. As such, 42 U.S.C. § 7573 preempts states from adopting or enforcing *"any standard respecting emissions of any air pollutant from any aircraft or engine thereof unless such standard is identical"* to USEPA's standards. On January 11, 2021, USEPA adopted new greenhouse gas (GHG) emission standards that apply to apply to civil subsonic jet airplanes and larger civil subsonic propeller-driven airplanes.[1] Notably, the standards are equivalent to the airplane carbon dioxide standards adopted by the International Civil Aviation Organization in 2017.[2] In the preamble to the final rule, USEPA notes, *"These standards will ensure control of GHG emissions, maintain international uniformity of airplane standards, and allow U.S. manufacturers of covered airplanes to remain competitive in the global marketplace."*[3] Thus, CARB should account for emission reductions in the aviation industry due to compliance with the new federal GHG emissions standards for airplanes, but should not presume that it can impose more restrictive emission standards than exist at the federal level.

In addition, intrastate fossil jet fuel represents a small fraction of jet fuel supplied in California and jet fuel suppliers do not know how much of the fuel is consumed intrastate versus interstate or out of the country. This makes compliance with the proposed obligation extremely complicated.

Re: WSPA Comments on August 18th CARB Workshop to Discuss Potential Changes to LCFS

Dear Dr. Laskowski,

Western States Petroleum Association (WSPA) appreciates the opportunity to comment on the staff presentation at California Air Resources Board (CARB) Workshop to discuss potential changes to the Low Carbon Fuel Standard (LCFS), held on August 18, 2022. WSPA is a trade association that represents companies that provide diverse sources of transportation energy throughout the West, including California. This includes the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies. Provided below is WSPA's initial feedback with references to the staff presentation slides[1] on CARB's proposed changes in the LCFS Program as presented to stakeholders by CARB staff on August 18, 2022:

Pathway Streamlining – Deemed Complete Date (Slides 9-13) – WSPA appreciates CARB's efforts to streamline LCFS program implementation. Although the alignment of deemed complete status reduces some confusion, changing the "*deemed complete date"* for Tier 2 pathway applications does little to streamline the pathway application process or resolve the issues with fuel pathway processing. Currently, for Tier 2 applications, the deemed complete date has little effect on credit generation, given that application reviews and validations are taking several months to complete. Ultimately, availability of the certified pathway often occurs multiple quarters after the deemed complete date. To achieve substantive changes in application processing, WSPA recommends that CARB incorporate into the regulation a deadline of 30 calendar days for CARB to review fuel pathway applications. If the applications are not reviewed within 30 days, the pathway application process should move on to the next step, such as the third-party validation step or the fuel pathway certification step. WSPA also recommends that CARB set staffing levels such that smooth and effective fuel pathway review processes can be achieved.

Temporary Pathway Credit True-Up (Slides 14-18) – WSPA supports the CARB staff proposal to true-up temporary fuel pathways with provisional and operational CI values. As CARB staff develops the draft regulatory language to implement this true-up element, we offer several factors to consider:

- The true-up should cover all volumes reported back to the first quarter during which the temporary pathway was used. Slide 16 suggests that it would be the first "full" quarter. This is an unnecessary limitation.

[1] https://ww2.arb.ca.gov/sites/default/files/2022-08/August%202022%20Workshop%20Slide%20Deck%20Presentations.v16.pdf – Accessed 9-12-2022

- True-ups should be automatic. Once CARB has certified a provisional or permanent pathway, credits should be added to the applicant's LRT-CBTS account without any administrative approval step.

- It is possible that a pathway holder may not be the fuel reporting entity for their pathway. In that case, they should have the option to designate another party to receive the true-up credits as part of their pathway application.

- True-ups should be applicable to pathways under review at the time that the regulatory changes take effect, including pathways still under provisional status.

WSPA also supports the proposal made during the public comment period to extend true-ups to the annual fuel pathway reporting process as well. Following verification, fuel pathway holders should be rewarded for incremental improvement in their operational carbon intensity. Doing so on an annual basis would reduce the need for pathway holders to reapply for their pathways to capture the value of operational improvements.

Hydrogen Tier 1 Calculator (Slides 19-23) - WSPA supports the establishment of a Tier 1 calculator for hydrogen. For a rapidly growing segment of the California LCFS program, this proposal may serve to streamline hydrogen applications so that focus can be placed properly on other complex Tier 2 pathways. For hydrogen pathways produced by steam hydrocarbon reforming, WSPA requests that CARB incorporate into the Tier 1 calculator all renewable hydrocarbons, (other than biomethane or renewable natural gas) as acceptable components to produce renewable hydrogen. An illustrative example is a renewable fuel facility that produces renewable propane as a co-product resulting from the conversion of renewable feeds to produce renewable diesel and/or alternative jet fuel. The renewable propane can be sent to the hydrogen plant as feedstock or used as thermal energy in the process heater for the hydrogen plant. Thus, the hydrogen derived from that portion of the renewable propane should be recognized as renewable hydrogen and should qualify for the hydrogen refueling infrastructure crediting program.

EMFAC Model Estimation (Slide 45) – WSPA does not support the use of EMFAC as a source of data for generating base credits for residential EV charging. EMFAC's primary purpose is to estimate the emissions inventories of on road mobile sources in California in the aggregate. CARB staff Slide 45 states: "*EMFAC is not designed to estimate residential PEV charging - estimates are not intended to reflect charging behavior" and "modifications would need to be made to transform model outputs into an estimate of residential PEV charging"*. As such, EMFAC may not be the best tool for accurately calculating credits for residential EV charging.

WSPA appreciates the opportunity to provide comments on this important regulatory process. If you have any questions regarding this submittal, please contact me at (360) 296-0692 or via email at jverburg@wspa.org.

Re: WSPA Comments on November 9 CARB Workshop regarding Potential Changes to LCFS

Dear Dr. Laskowski,

The Western States Petroleum Association (WSPA) appreciates the opportunity to comment on the staff presentation at the California Air Resources Board (CARB) workshop to discuss potential changes to the Low Carbon Fuel Standard (LCFS), held on November 9, 2022. WSPA is a trade association that represents companies that provide diverse sources of transportation energy throughout the west, including California. This includes the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies.

Provided below is WSPA's feedback regarding the CARB staff presentation[1] on proposed changes in the LCFS Program as provided to stakeholders on November 9. WSPA has previously submitted comments to CARB staff pursuant to the CARB's July 7 and August 18 LCFS workshops. Those comments are incorporated into this letter by reference.[2,3]

CATS Model Overview (Slides 12-21)

The California Transportation Supply (CATS) Model is intended to develop optimized scenarios based on the user input. CARB needs to assess that the basis for its inputs to CATS are technically sound, in particular for emerging technologies. WSPA recommends that CARB develop sensitivity analysis for different input variables, including (but not an exhaustive list):

- Various gasoline demand scenarios, including flat gasoline demand or gasoline demand not dropping as fast as expected in the original scenario.
- Different electricity prices, as the cost of electricity seems to be too low if set at 80 $/MWh as stated in Slide 16. The United States Energy Information Administration (EIA) recently reported that in September 2022, the "average price of electricity to ultimate customers" for the transportation sector in California was 15.63 cents/KWh (equates to 156.30 $/MWh).[4] In addition, modeled scenarios for future years should take into account upward pressures on electricity rates such as those presented by the California Energy Commission in their

[3] Western States Petroleum Association. "WSPA Comments on the August 18th CARB Workshop to Discuss Potential Changes to the LCFS", September 19, 2022.
[4] https://www.eia.gov/electricity/monthly/epm_table_grapher.php?t=epmt_5_6_a.

September 21, 2021, Demand Analysis Working Group which shows forecasted statewide commercial and residential rates greater than 20 cents/KWh in 2030 and beyond.[5]

- A range of crude oil price ranges, rather than a single 90 $/barrel proposed on Slide 16 and Table 4 of the CATS documentation.

CATS should also model the additional cost of electricity for building up the electric vehicle (EV) charging infrastructure and the construction of additional power generation.

Table 8 of the "Draft California Transportation Supply Model – Technical Documentation" (hyperlink to document provided on Slide 21) shows a significant difference between the fixed cost of CARBOB production and the fixed cost of ultra-low sulfur diesel (ULSD) production. WSPA requests that CARB provide more information on how these fixed costs are established as ULSD and CARBOB are co-produced at oil refineries. CARB should also confirm whether the biodiesel equivalence value under the United States Environmental Protection Agency's Renewable Fuel Standard (RFS) program should be 1.5 rather than 1.4 as stated on Page 20 of the "Draft California Transportation Supply Model – Technical Documentation."

CATS Summary Input Spreadsheet – Fuel Production Tab – Exogenous Subsidy (Slide 21)

In reviewing the "core model inputs" (hyperlink to spreadsheet provided on Slide 21), WSPA requests that CARB staff confirm if the 0.369 $/MJ value of compressed natural gas (CNG) is correct, or if it should instead be 0.0369 $/MJ. The 0.369 $/MJ corresponds to nearly $390 million per BTU – which seems very high. It is also requested that CARB provide the basis for the renewable gasoline 0.019 $/MJ exogenous subsidy.

Scenario Design: Carbon Intensity (Slides 25-26)

WSPA is concerned about the current pace of the LCFS rulemaking. CARB proposes to significantly accelerate near-term LCFS targets and potentially extend targets as far out as 2045. However, CARB staff is just beginning to assess potential compliance scenarios. The presentation during the November 9 workshop described high-level compliance curves, with little transparency into the methodology and no discussion of feasibility. To meet a January 2024 implementation date, these scenarios need to be presented in a more comprehensive manner, with transparency and significant stakeholder input. Without that, it is difficult to comment on the three compliance curves presented. Consequently, we can only comment on the modeling inputs described by CARB staff.

For example, Slide 6 shows that the program only slightly "overperformed" – by 0.61% carbon intensity (CI) reduction in 2021 (9.36% CI reduction vs. 8.75% CI target) – which is only about half of the current annual increase in the CI benchmark. If the pace of adopting Zero Emission Vehicles does not occur as planned into 2030, the number of deficits will far exceed any credits being generated. Yet this scenario is not being evaluated as part of the scenarios. As a result, CARB should be careful in setting more stringent CI standards and ensure that the new CI standards do not quickly exhaust the credit bank.

In addition, CARB should include in the proposed regulatory language a provision that stipulates a formal annual program review with an option to reset the benchmarks in the event that credit generation falls short or/and deficit generation is higher than expected.

---

[5] CEC Demand Analysis Working Group (https://www.energy.ca.gov/sites/default/files/2021-09/1%20Electricity%20Rate%20Forecast%20Updates_ADA.pdf) – Accessed 12-15-2022

Crop-Based Biofuel (Slides 28-29)

As WSPA stated in our August 8 comment letter, no arbitrary limit should be set on crop-based feedstock. Any concerns around land use impacts are handled in feedstock carbon intensity calculations. Indirect Land Use Change (ILUC) values already increase the CI score of renewable fuel produced from crop-based feedstocks, resulting in lower emission reductions attributable to the fuels. An artificial limit on supply is not the appropriate method of accounting for these impacts.

Food supply concerns are similarly addressed by ILUC inputs to carbon intensity scores. It is noteworthy that the 2018 LCFS readoption evaluated several different fuel supply scenarios[6] with varying amounts of biodiesel and renewable diesel available to support the LCFS's goal of reducing the CI of fuels in California 20% by 2030. The scenario chosen to illustrate a feasible program estimated the growth of biodiesel and renewable diesel would be on the order of 146% (and evaluated growth up to a 215% increase) from 2018 levels through to 2030. Much of the anticipated growth in these fuels has already been considered by CARB, including potential land use impacts and other factors[7]. Today, feedstock availability is aligning with expectations from the 2018 LCFS readoption. As shown in the 2018 illustrative compliance calculator,[8] CARB forecasted the CIs for biodiesel and renewable diesel to be 34 gCO2e/MJ for biodiesel and 30 gCO2e/MJ for renewable diesel into 2030. As of Q2 2022, CARB has reported[9] average CI values of 27.51 gCO2e/MJ for biodiesel and 35.96 gCO2e/MJ for renewable diesel. Given investments taking place, additional restrictions should not be created as anticipated growth of these fuels and impact to land use has already been considered.

Additionally, no data has been presented by CARB or other stakeholders suggesting that any threat to food supply has been created by growing biofuel demand. It is noteworthy that while CARB is proposing limits on crop-based feedstock, the proposed regulation encourages the increased development of renewable electricity sources (specifically solar) which will undoubtedly result in the conversion of agricultural lands. WSPA believes that this duplicity in policy is concerning and sends a mixed message to stakeholders.

Rather than establish artificial limits on crediting for specific fuels, WSPA encourages CARB to continue analyzing land use change factors and focus on CI score accuracy. WSPA also requests that CARB define the term "virgin crop-based oil." Specifically, the definition should not include cover crops. Cover crops are used to slow erosion, improve soil fertility and quality, and help control pests and diseases.

Biomethane Crediting (Slides 30-32)

CARB staff presented potential scenarios for limiting crediting for biomethane, including arbitrary geographical limits and a phase-down of avoided methane crediting without providing a clear approach as to how CARB would implement these changes. For example, it is not clear whether or not the gas to a hydrogen production facility (a legacy pathway not tied to a landfill renewable natural gas (RNG) facility book-and-claim) would be removed from crediting as of 2030. Clarity around considerations such as this is important for stakeholders to understand and to provide meaningful feedback. Because biomethane crediting has been a major contributor to the success of the LCFS program, to arbitrarily limit those credits threatens the continued success of the program. It is also contrary to the technology neutral, market-based nature of the LCFS program.

---

[6] CARB 2018 rulemaking. Illustrative Compliance Calculator.
[7] CARB 2018 Environmental Analysis.
[8] *Supra*, tab "Calculations" Row's 57 and 58.
[9] CARB LCFS Quarterly Data Spreadsheet.

CARB cited a desire to focus biomethane use in hydrogen production and non-transportation use. The proper way to do so is to establish incentives that encourage use in those applications, rather than simply removing incentives elsewhere. As producers discussed during the November 9 workshop, such an approach is more likely to slow or even reverse investments in methane capture. Rather than limit crediting for biomethane under the LCFS, CARB should be looking for ways to establish credit, such as removing the limit on book-and-claim treatment for biomethane used for process energy in refineries and crude production facilities.

Further, WSPA believes that CARB should not attempt to harmonize RNG with electricity (see Slide 32) as the natural gas pipeline is vastly different from the electricity grid. For example, there is more flexibility to move gas longer distances than the electric grid is capable of. If Alternative A or B is adopted, then CARB should grandfather in all current pathways that have RNG facilities located outside of the "Western NG network" as project investment was based upon dispensing in California.

Other Modeling Assumptions Under Consideration (Slide 35)

CARB included a phase out of petroleum project-related crediting in two of the scenarios presented without describing the rationale behind such a change. Given that all scenarios involve continued use of petroleum products in the coming decades, it is contrary to the goals of the LCFS program to discourage carbon reduction projects at crude production and refining facilities.

Rather than arbitrarily constrain these credits without science-based drivers, CARB should be removing current barriers to qualification. Innovative Crude credits are currently restricted to a discrete set of technologies and should be expanded to enable emerging technologies and efficiency investments that reduce carbon emissions. Similarly, the use of biomethane in both crude production and refining facilities should be allowed book-and-claim treatment.

WSPA continues to object to the addition of deficits for intrastate fossil jet use. This is a needlessly complicated addition to the program for a very small portion of jet fuel demand in the State. It would have little impact on alternative jet fuel demand and create considerable work for aviation stakeholders, CARB staff, and verifiers (i.e., fuel producers and importers do not know who controls how much of the jet fuel that is consumed in intrastate flights – nor do they have access to this information). However, if CARB decides to implement such a LCFS obligation on intrastate jet fuel, the obligation should not be borne by fuel producers or importers.

WSPA appreciates the opportunity to provide comments on this important regulatory process. If you have any questions regarding this submittal, please contact me at via email at tderivi@wspa.org.

Re: WSPA Comments on CARB Preliminary Discussion Draft of Potential Low Carbon Fuel Standard Regulation Amendments and February 22, 2023 LCFS Workshop

Dear Dr. Laskowski,

The Western States Petroleum Association (WSPA) appreciates the opportunity to comment on the Preliminary Discussion Draft of Potential Low Carbon Fuel Standard (LCFS) Regulation Amendments and the associated staff presentation at the California Air Resources Board (CARB) workshop, held on February 22, 2023. WSPA is a trade association that represents companies that provide diverse sources of transportation energy throughout the west, including California. This includes the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies.

In considering potential amendments to the LCFS Regulation, it is essential to recognize that LCFS adds approximately 11 cents per gallon to the cost of California gasoline according to the California Energy Commission.[1] While California continues to face serious supply constraints as it relates to transportation fuels and the California legislature considers how to provide relief at the pump for California drivers, CARB should ensure that its proposed LCFS regulation amendments do not increase costs uniquely impacting California fuels. Proposed amendments including arbitrary caps on alternative fuel pathways, hydrogen production and a self-ratcheting mechanism, among other amendments, will likely increase costs of California fuels. WSPA is generally concerned with proposed amendments to the LCFS regulation that could further compromise the supply reliability of critical transportation fuels, a consequence of which could be increasing energy costs at a time when energy affordability is a pressing priority for many Californians.

The LCFS program is primarily a liquid fuels program, for which WSPA members have made significant investments to help make the program both successful and replicable. WSPA supports LCFS and believes that the program should continue to provide an appropriate market signal that incentivizes the production of low-carbon intensity (CI) fuels. The LCFS should continue to preserve consumer choice and provide a level playing field for all technologies. The market-based program should embrace fuel- and technology-neutral principles that focus on the meaningful and timely reduction of GHG emissions. Because step changes on CI stringency would be required upon adoption of final regulatory language starting as early as 2024, LCFS should provide a clear and durable market signal for investments in the production of lower CI technologies with sufficient time from adoption to implementation for obligated parties to plan for investments and deployment plans for technologies.

[1] Based on OPIS data; CEC staff presentations at https://www.energy.ca.gov/event/workshop/2022-11/commissioner-hearing-california-gasoline-price-spikes-refinery-operations

Provided below is WSPA's feedback regarding the Preliminary Discussion Draft of Potential LCFS Regulation Amendments and CARB staff presentation[2] from the February 22nd workshop. WSPA previously submitted comments pursuant to CARB's July 7th, August 18th, and November 9th LCFS workshops. Those comments are incorporated into this letter by reference.[3,4,5]

General Comments

Arbitrary Caps on Alternative Fuels Pathways

CARB continues to discuss the concept of placing an arbitrary cap on crop-based fuels but has not yet presented data to demonstrate what problem the cap would address. CARB staff even mentions on Slide 37 that they have *"received limited data, analysis and supporting documents."* Since there is no majority of stakeholders presenting a compelling argument in favor of such a significant programmatic change, this concept should be set aside unless a verifiable issue arises. In fact, an arbitrary cap on crop-based fuels would go against Health and Safety Code Section 38560, the statutory basis for CARB's proposed set of actions, which requires CARB "to achieve the maximum technologically feasible and cost-effective greenhouse gas emission reductions from sources."[6] When all options must be on the table, CARB's concept would be *limiting* proven GHG reductions strategies that are technologically feasible and cost effective, and have garnered significant GHG reductions in the past.

We would also like to once again point out that CARB has already included a control mechanism for potential land use change concerns. This is precisely what the ILUC factors in CI modeling are meant to do, so additional limits are not needed nor appropriate. WSPA believes that adding an arbitrary cap would unnecessarily respond to an issue that was addressed long ago in the LCFS program.

Hydrogen Production

All hydrogen production pathways should be considered based on their CI reduction potential. Similar to what has been discussed above, a more robust hydrogen infrastructure has shown to be a technologically feasible, cost-effective way to reduce GHG emissions, which is what Health and Safety Code Section 38560 requires CARB to accomplish. WSPA does not support either the exclusion of hydrogen derived from fossil fuels from book-and-claim eligibility or the exclusion of hydrogen production by steam methane reforming in Medium- and Heavy-Duty Hydrogen Refueling Infrastructure (MHD-HRI) crediting. There is already a severe shortage of hydrogen refueling options across California (especially in relation to electric charging options) – just as CARB prepares to adopt the proposed Advanced Clean Fleets regulation that will demand the immediate and exponential growth of hydrogen refueling options for MHD vehicles.

We urge CARB to avoid proposed amendments that would arbitrarily constrain hydrogen production at a time when California consumers need more affordable fuel options – not less.

[6] Cal. Health & Safety Code § 38560.

CATS Model

CARB staff stated at the February 22nd LCFS workshop that the California Transportation Supply (CATS) Model would be released within a week for stakeholders to evaluate and use. According to CARB's document, the CATS Model *"can be used to explore how different assumptions relating to the cost, supply, demand, and carbon intensities of various fuel may impact the transportation market, and how Low Carbon Fuel Standard credit prices may respond to changes in market conditions and program stringency."*[7] WSPA subsequently inquired with CARB staff on the status and timing to comment when that week-long timeframe had passed. As the CATS modeling has yet to be released, we along with other stakeholders are unable to offer robust comments at this time.

Providing the CATS modeling with adequate review time would have helped stakeholders raise issues for CARB staff or to seek clarification from CARB staff regarding important input assumptions being used to inform CARB's modeling of future LCFS requirements. Even without the CATS modeling release, WSPA does have questions about various modeling assumptions, including cost of compliance, how feedstock pricing was established, inclusion of fixed cost regression for some fuel components, interim pricing for intrastate Sustainable Aviation Fuels, inflationary assumptions, costs associated with fossil fuel sales, and other important variables.

Specific Comments – CARB Staff Presentation

Slide 11 – Alternative Fuel Diversification

CARB staff rightfully noted in their introductory comments that *"LCFS drives investment and fuel diversification"* and that further investment is needed to meet accelerated targets. It is concerning, however, that CARB staff then proposed a number of changes that would scale back existing investments and discourage future growth. This includes dramatic increases in biogas carbon intensity, artificial caps on crop-based fuels, halving credits for ZEV forklifts, and phasing out crediting for GHG reduction at upstream and refining facilities. Further constraining fuel options just as CARB seeks to increase the program's stringency is the wrong approach for Californians. Such proposals would also go against Health and Safety Code Section 38560 which requires CARB to seek out technologically feasible, cost-effective GHG reduction mechanisms.

Slide 15 - Self-Ratcheting Mechanism

The second bullet on Slide 15 identifies as an element of the rulemaking scope: "*Mechanisms to auto-adjust CI targets to accelerate investment if program is over-performing."* WSPA recommends against a self-ratcheting mechanism that would auto-adjust the CI targets. We believe that rulemaking is the appropriate process to update the CI targets, because it is what is expected under basic principles of California administrative law,[8] and because a self-ratcheting mechanism would defeat the spirit of the LCFS regulation, which is to allow banking of LCFS credits for future use as the program becomes more stringent over time. It would also not appear to account for exceptional circumstances, such as the COVID pandemic nor recessionary-driven slowdown, that have demonstrably significant impacts on the fuels market as well. A self-ratcheting mechanism may lead to an excessive use of LCFS credits in the short term to the detriment of long-term compliance

[7] https://ww2.arb.ca.gov/our-work/programs/low-carbon-fuel-standard/lcfs-meetings-and-workshops.
[8] *See* Cal. Gov't Code § 11346.2 (discussing the notice-and-comment process); *POET, LLC v. State Air Res. Bd.*, 218 Cal. App. 4th 681, 744 (2013), *as modified on denial of reh'g* (Aug. 8, 2013) ("agencies must . . . (1) give the public notice of the proposed regulatory action; (2) issue a complete text of the proposed regulation with a statement of reasons for it; (3) give interested parties an opportunity to comment on the proposed regulation; (4) respond in writing to public comments; and (5) maintain a file as the record for the rulemaking proceeding").

options. Further, such mechanism fails to provide market certainty.

Slide 16 - Rulemaking Process

CARB staff lays out a very general rulemaking process on Slide 16 without discussing timing. Given the progress to date on this rulemaking, WSPA urges CARB staff to identify an achievable implementation date for any regulatory changes made and to publish a detailed rulemaking calendar.

Slide 25 (and Slide 52) - Compliance Target Step Down and Acceleration Mechanism

This is the first workshop during which CARB officially discussed the concept of an "acceleration mechanism." We find this concept concerning as it shortcuts the deliberative, public process of a formal rulemaking (i.e., an "acceleration mechanism" could remove credits from the bank too quickly and risk rendering the program infeasible in the later years when the CI standards become ever more stringent) which the public is entitled to under basic administrative law principles in California.[9] The credit bank should be looked to as a long-term compliance option. We also believe that any market indicators identified could result in serious unintended consequences such as credit shortages or market volatility. With the concept under consideration, such consequences could only be addressed through emergency actions by CARB, followed by an immediate rulemaking.

Regarding the potential triggers CARB listed, a credit price trigger is the least appropriate. While the LCFS is intended to spur investment, CARB should not seek to fix prices. The price cap in the Credit Clearance Market is there as a relief valve to avoid harmful spikes. Setting an effective price floor would represent market manipulation. Furthermore, markets are volatile. Establishing a price trigger could lead to frequent, disruptive alterations to compliance targets. Adding such volatility to California's fuel market would be highly inadvisable.

However, of the triggers CARB identified, the total credit bank size would be the most appropriate. If the credit bank size were used as a trigger, it would obviously behoove CARB to include automatic "deceleration" of targets should the credit bank become very low or negative. It is unclear what "credit to deficit ratio" means as a trigger for changing targets.

Finally, the LCFS credits modeled by CARB is above the maximum allowed credit price, which indicates a shortage of credits. Therefore, no step-change should be considered in the program. Rather CARB should establish CI standards that can be met while maintaining the LCFS credit price below the maximum allowed price.

Slide 29 - ZEV Refueling Infrastructure

While the replication of the light-duty ZEV refueling infrastructure language for medium- and heavy-duty vehicles is appreciated, it is critical that CARB staff identify a reasonable mechanism for modeling "hybrid" stations to avoid creating a requirement for the duplication of storage-to-dispensing infrastructure.

Slide 32 - Methane Crediting

CARB staff cited a desire to focus biomethane use in hydrogen production and non-transportation use. The proper way to do so is to establish incentives that encourage use in those applications, rather than simply removing incentives elsewhere. As stakeholders discussed this issue during

[9] Please see discussion in Footnote 7.

previous LCFS workshops, such an approach is more likely to slow or even reverse investments in methane capture. Rather than limit crediting for biomethane under the LCFS, CARB should be looking for ways to *establish* credit, such as removing the limit on book-and-claim treatment for biomethane used for process energy in refineries and crude production facilities.

WSPA also believes that Avoided Methane Crediting is needed to support current and future investment and project development. These credits for methane – that was previously emitted or flared – are key components of dairy renewable natural gas (RNG) investments and should be preserved to ensure the maximum production of clean fuels and emission reductions.

Further, WSPA recommends that CARB not attempt to harmonize RNG with electricity as the natural gas pipeline is vastly different from the electricity grid. For example, there is more flexibility to move gas longer distances than the electric grid is currently capable of.

Slide 35 - Intrastate Jet Fuel

WSPA continues to object to the addition of deficits for intrastate fossil jet use. This is a needlessly complicated addition to the program for a very small portion of jet fuel demand in the state. It would have little impact on alternative jet fuel demand and create considerable work for aviation stakeholders, CARB staff, and verifiers. Crediting for alternative jet fuel is based on delivery to airport storage, while the proposed deficits would be based on consumption during intrastate flights. Given that, blending more alternative jet fuel would not reduce the deficits generated by airlines for intrastate flights. This means that these added deficits would simply make the airlines credit purchasers in the program and would not incentivize increased blending of alternative jet fuel.

If CARB decides to implement a LCFS obligation on intrastate jet fuel, WSPA agrees that the obligation should not be borne by fuel producers or importers (but rather the airlines that will use the jet fuel) as fuel producers and importers do not control the volume of jet fuel that is used for intrastate travel. This would enable more direct tracking of intrastate jet consumption.

Slides 36-41 - Crop-Based Fuels

As a follow-up to the General Comment above and consistent with past WSPA comment letters, no arbitrary limit should be set on crop-based feedstock. A free-market CI based policy should drive technology choices and there should not be additional prohibition mechanisms in favor/or against certain technologies. ILUC values already increase the CI score of renewable fuel produced from crop-based feedstocks, resulting in a lower economic value for these fuels compared to fuels produced from waste-based feedstocks. CARB should let the market optimize the fuel slate based on market economics and feedstock availability and not set arbitrary constraints.

WSPA further suggests that Best Farming Practices be included in, and accounted for, within the program CI calculation methodology to properly credit “climate smart” agricultural practices. Doing so would recognize the projected GHG mitigation and carbon sequestration benefits associated with ongoing or new and innovative farming practices associated with the intentional production of climate-smart commodities (e.g., reduced use of fertilizer, targeted fertilizer nutrients, soil carbon sequestration, etc.).

Slide 43 - Project-Based Crediting – Phase Out

WSPA objects to an artificial phase out of project-based crediting and limiting the duration of the crediting period of these projects, as project-based crediting incentivizes incremental GHG emission reductions. Such an approach is arbitrary and discourages investment in real GHG reduction investment at refineries and oil producing facilities. Rather than arbitrarily constrain these credits without science-based drivers, CARB should be removing current barriers to qualification. Innovative Crude credits are currently restricted to a discrete set of technologies and should be expanded to enable emerging technologies and efficiency investments that reduce carbon emissions – especially given the strong and long-term demand for these fuels identified in the 2022 Scoping Plan Update.

Similarly, the use of biomethane in both crude production and refining facilities should be allowed book-and-claim treatment. Restricting book-and-claim for RNG to CNG transport outlets but not for hydrogen feedstock dispositions again seems to be attempting to pick "winners and losers" based upon long-term speculative market forecasts. We continue to support a free market-based policy and level playing field for various RNG pathways. To that end, we support maintaining the robust tracking, traceability, and documentation requirements and continuing to allow book-and-claim from all existing geographies for all RNG pathways, as this represents the best path forward to achieve more stringent LCFS targets.

Slide 48 - LCFS Modeling Framework

WSPA requests detailed clarification of the CATS Model assumptions. Areas of concern identified from information available to date include but are not limited to the following:

- The model does not appear to be tracking any possible increase in the cost of fossil fuel sales in the model (or are not explaining how it is included), which may incorrectly increase the cost of compliance.
- Inflation does not seem to be factored into the model; more clarification is needed on assumptions and methodology.
- The Sustainable Aviation Fuel (SAF) model appears to reflect only the interim SAF pricing in years 2023-24 versus 2025-27. It is not clear if an entity can carry this forward beyond the years approved. The model is showing soybean oil SAF with a $1.25/gallon subsidy at 50% CI reduction, or 42 CI. This indicates the assumptions used citing the federal Inflation Reduction Act are based on 40B New SAF credits rather than 45Z New Clean Fuel Production credits, which would make better sense.
- More clarity is needed as to how feedstock pricing was established.
- More clarity is needed as to whether the model is assuming an infinite amount of virgin oil feedstock available, driven only by increasing price.
- More clarity is needed on how the model estimates higher fossil and agriculture benchmark costs, relative to historic values.
- The fixed cost regression for FAME and Renewable Diesel is confusing (as well as the one for CARBOB and ULSD) – additional clarification is needed.
- While the model has a fixed price of $1.45/RIN for D4s and FAME RIN equivalence of 1.4 (vs 1.5) and D6s are modeled at $1.13/RIN, a reference for D3s cannot be found.

Slides 49-51 - LCFS Modeling Outputs

Slides 49 and 50 show a significant destruction of gasoline demand over time, yet the diesel pool continues to have a sizable proportion of petroleum diesel. WSPA suggests that CARB evaluate an alternative scenario where the entire pool of petroleum diesel is replaced with renewable diesel and biodiesel blends over the next few years. As alternative fuels saturate the market to near-completion, there should be a step change in credit generation that slows credit generation; it is more difficult to substitute petroleum CARBOB with renewable fuels, due to several constraints, including ethanol blending limits. In particular, if the growth of electric vehicles does not materialize as fast of CARB's current prediction, the deficit generation from CARBOB may be challenging to balance with credits. This uncertainty should also be modeled.

Slide 51 shows the LCFS credit price going over the maximum credit price which suggests a shortage of credits to balance the deficits. Therefore, WSPA requests that CARB also model a CI standard curve where the LCFS credits remain below the LCFS maximum credit price throughout the duration of the modeled period. Another modeling scenario CARB should consider is incorporating the bank of credits held by firms today, by including the credit bank in any forward forecast; including the credits will allow stakeholders to assess how CARB's potential updates will impact the current market.

Slides 62-64 - Updates to Tier 1 Calculators

WSPA supports the development of a new hydrogen calculator. CARB should also include options for renewable hydrocarbon feedstocks, such as renewable propane and other renewable hydrocarbon and hydrocarbon mixtures (such as ethane, propane, butane, etc.) in the steam reforming hydrogen calculator.

In addition, WSPA requests that CARB update the definition of renewable hydrogen to allow infrastructure crediting for hydrogen fuel produced from renewable hydrocarbons other than biomethane/renewable natural gas, by including renewable ethane, renewable propane, renewable butane and other renewable hydrocarbons and a mixture thereof.

Slide 69 - OPGEE

WSPA requests that CARB eliminate the incremental deficit provision from imported petroleum CARBOB and petroleum ULSD (CARB diesel). CARBOB and ULSD produced at refineries outside California do not process the same crude slate as the crude slate processed in California, and therefore, the incremental deficit calculations are not relevant for imported products.

WSPA also requests that CARB release the latest dataset from 2019 used to establish crude baselines in OPGEE. This is an important step to maintain the model's transparency.

Side 70 - Verification Updates

MCON (Crude) Reporting - Refineries should not need to report California crudes by field name in the MCON report as CARB is not using this information. CARB is using the data from the Department of Conservation. Therefore, no verification of California crudes should be required.

Site Visits - No site visit should be required other than for fuel pathway verification. Video conferencing and screen sharing are sufficient for other types of verification.

Quarter 3 LCFS Reporting Deadline - WSPA requests that CARB change the Q3 reporting date from December 31st to January 15th to allow time for the winter holidays.

<u>Specific Comments – Proposed Regulatory Text</u>

§95486.3(a)(1)(B): This section would require proposed MHD-HRI stations to be located in California within one mile of a Federal Highway Administration Alternative Fuel Corridor. WSPA requests that CARB provide the rationale for placing limits on designated corridors and locations rather than leaving the market to define those locations based upon real world demands.

§95486.3(a)(1)(C): This section would allow application on MHD-HRI pathway application through December 31, 2029. WSPA requests that application submissions for light-duty HRI be extended to the same date as well in section §95486.2(a)(1)(B) and §95486.2(a)(7).

§95486.3(a)(2)(E): This proposed section references the HySCapE model. WSPA requests that CARB clarify if there will be a different version of the HySCapE model – one for heavy-duty and one for light-duty hydrogen fuel cell vehicles – or if the same HySCapE model will be used in any case.

§95486.3(a)(3)(A): This section includes an equation for estimating potential MHD-HRI credits. WSPA suggests that CARB consider additional language for exemptions and waivers considerations and provide clarity on credit equation for extreme cases where an approved station is not operational for an extended period after approval (extreme case).

§95486.3(a)(4)(B): This section requires that the station must be open to at least two different trucking companies. WSPA suggests eliminating this restriction on station owners.

§95486.3(a)(4)(D): This section requires that at least three Original Equipment Manufacturers have confirmed that the station meets protocol expectations, and their customers can fuel at the station. WSPA requests that CARB provide the reasoning behind this rigorous requirement.

§95486.3(a)(5): In the equation for the calculation of MHD-HRI credits, it appears that the CI_{HR} factor is not the same CI_{HR} factor delivered to the actual station *("… is the carbon intensity used for HRI crediting. Company-wide weighted average CI for dispensed hydrogen during the quarter or 0 g/MJ, whichever is greater")*. WSPA requests further information on this CI input.

§95486.3(a)(6): In this section, certain requirements appear to include information that is competitively sensitive, business confidential information. WSPA requests that CARB identify how this information will be protected against disclosure. In addition, CARB needs to clarify what entities will have access to this information and why that access is necessary.

WSPA appreciates the opportunity to provide comments on this important regulatory process. If you have any questions regarding this submittal, please contact me at via email at tderivi@wspa.org.

Re: WSPA Comments on CARB's Proposed Low Carbon Fuel Standard Auto-Acceleration Mechanism and May 23, 2023 Workshop

Dear Dr. Laskowski,

The Western States Petroleum Association (WSPA) appreciates the opportunity to comment on potential changes to the Low Carbon Fuel Standard (LCFS), to add a mechanism that would accelerate the carbon intensity benchmarks if certain conditions are met, and the associated staff presentation at the California Air Resources Board (CARB) workshop held on May 23, 2023. WSPA is a trade association that represents companies that provide diverse transportation energy resources throughout the west, including California. These include the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies.

General Comments

In considering potential LCFS regulation amendments, it is essential to recognize that the LCFS adds approximately 11 cents per gallon to the cost of California gasoline according to the California Energy Commission (CEC).[1] As California continues to face serious transportation fuels supply constraints, the California legislature and the Governor recently approved legislation[2] attempting to address this fuel supply concern. This new statute requires CARB and CEC to prepare a Transportation Fuels Transition Plan "in consultation with the state's fuel producers and refiners" that "shall include, at a minimum, a discussion of how to ensure that the supply of petroleum and alternative transportation fuels is affordable, reliable, equitable, and adequate." WSPA looks forward to working closely with CARB and CEC to inform the Transition Plan's development – where fuel affordability and equity must be central considerations to help inform policies under the baseline assumption that internal combustion engine vehicles (including hybrid vehicles) will be used and needed by Californians for decades to come.

While the LCFS program has a maximum credit sale or transfer price of $200 (2016$) it is important that CARB ensure the potential LCFS amendments recognize the impacts of a change to costs uniquely impacting California fuels. WSPA is extremely concerned with proposed amendments that could further compromise the supply reliability of critical transportation fuels and destabilize the program – a consequence of which could be increasing energy costs at a time when energy affordability is a pressing priority for many Californians. Proposed amendments like a one-way auto-

[1] Based on OPIS data; CEC staff presentations at https://www.energy.ca.gov/event/workshop/2022-11/commissioner-hearing-california-gasoline-price-spikes-refinery-operations.

acceleration mechanism, among other potential changes, will likely increase California fuels costs. Newly inserting an automatic mechanism would be wholly inappropriate and set a bad precedent for a program that was developed through and has been amended multiple times since by formal rulemaking processes.

WSPA members have made significant investments to help make the LCFS program both successful and replicable. WSPA supports the LCFS and believes the program should continue to provide an appropriate market signal that incentivizes the production of low-carbon intensity (CI) fuels. This market-based program should focus on providing clear, meaningful, durable, and timely market signals for the reduction of greenhouse gas emissions through investments in the production of lower CI technologies, with sufficient time from adoption to implementation for obligated parties to plan for investments and deploy technologies.

Specific Comments – CARB Staff Presentation

Provided below is WSPA's feedback regarding the auto-acceleration mechanism under consideration for potential LCFS amendments and the CARB staff presentation[3] from the May 23rd Workshop. WSPA previously submitted comments pursuant to CARB's July 7, 2022, August 18, 2022, November 9, 2022, and February 22, 2023 LCFS Workshops. Those comments are incorporated into this letter by reference.[4,5,6,7]

Slide 7 – Scope of Rulemaking. The second bullet point on Slide 7 identifies mechanisms to auto-adjust CI targets to accelerate investment if the LCFS program is overperforming. WSPA recommends against including a (one-way) auto-adjustment of the CI targets. We believe that rulemaking is the appropriate process to update the CI targets, because it is what is expected under the basic principles of California administrative law,[8] and because such a mechanism would defeat the spirit of the LCFS regulation, which is to allow banking of LCFS credits for future use as the program becomes increasingly more stringent over time.

Instead of an auto-adjustment of the CI targets, WSPA suggests that CARB consider utilizing annual fuels forecasting to determine the need to adjust CI targets. For example, the Oregon Department of Administrative Services (DAS) annually completes a fuels forecast (pursuant to Oregon Administrative Rule 340-253-2100) to inform the Oregon Department of Environmental Quality (DEQ) as to the performance of the DEQ's Clean Fuels Program. A similar independent approach by CARB is encouraged for transparency and consistency.

An auto-adjustment of the CI targets would also appear to <u>not</u> account for exceptional circumstances – such as the COVID pandemic nor a recessionary-driven slowdown – that have demonstrably significant impacts on the fuels market. Instead, such an auto-acceleration mechanism may lead to

[8] *See* Cal. Gov't Code § 11346.2 (discussing the notice-and-comment process); *POET, LLC v. State Air Res. Bd.*, 218 Cal. App. 4th 681, 744 (2013), *as modified on denial of reh'g* (Aug. 8, 2013) ("agencies must . . . (1) give the public notice of the proposed regulatory action; (2) issue a complete text of the proposed regulation with a statement of reasons for it; (3) give interested parties an opportunity to comment on the proposed regulation; (4) respond in writing to public comments; and (5) maintain a file as the record for the rulemaking proceeding").

an excessive use of LCFS credits in the short-term to the detriment of long-term compliance options. Further, such a mechanism fails to provide the market certainty necessary to ensure petroleum and alternative transportation fuel supplies are affordable, reliable, equitable, and adequate as California's leaders seek to achieve.

Slides 11-12 – Compliance Target Step Down and Acceleration Mechanism Concepts. This was the first workshop where CARB officially discussed details of an "acceleration mechanism." Previously, there was only one workshop where a broad concept was presented. WSPA finds the concept (and the late introduction of details) that introduces a complex structural change to the LCFS program at the very end of the informal rulemaking process concerning. Because such a mechanism could remove credits from the bank too quickly, it risks rendering the LCFS program infeasible in the later years when the CI standards become ever more stringent for regulated entities to comply with. Yet CARB provides no mechanism to *reverse* any unintended consequence of this action as the only options presented to date (including by third party stakeholders without compliance obligations) operate only to *increase* CI benchmarks.

WSPA believes this would be a significant enough structural change that further stakeholder discussion, analysis, and modeling is required. We strongly encourage CARB not to include the concept in the upcoming 45-day package to be released within the next several weeks and to instead separate it from the forthcoming rulemaking to allow for further discussion and evaluation.

Slides 15-25 – Different Ways to Implement the Auto-Acceleration Mechanism. WSPA believes incorporating an auto-acceleration mechanism into the LCFS program now would be premature. Compromising the health of the program without sufficient analysis, in an effort to artificially inflate LCFS credit prices, would be inappropriate and highly problematic by unnecessarily increasing programmatic and market complexities at a time when the transportation sector is already working through dramatic transformation. It also presumes that fuel supply and demand scenarios will perform as envisioned to meet the ambitious 2022 Scoping Plan Update goals – that supply will phasedown in line with demand – despite known uncertainties in the energy market itself rather than seeking to ensure supply and demand for liquid fuels remains harmonious.

The credit bank is and should continue to be looked to as real emission reductions that regulated entities may use as a long-term compliance option. We also believe that any market indicators identified could result in serious unintended consequences such as credit shortages or market volatility. With the concept under consideration, such consequences could only be addressed through emergency actions by CARB, followed by an immediate rulemaking.

Should CARB proceed with incorporating this concept into the program through the upcoming formal rulemaking process, WSPA believes that additional work and stakeholder engagement is necessary. This should also include incorporating a means to reverse or "release" an auto-accelerator mechanism to avoid cementing overly ambitious forward CI benchmarks in place if the market would struggle to comply and compromise the integrity of the program. As the CARB Governing Board has exercised with multiple regulations before, we would encourage the Governing Board direct CARB's Executive Officer to work with stakeholders and perform additional analysis and then return later for formal approval.

We encourage CARB to provide regular periodic review of the program's performance to assess what additional changes would be required and discussed through a formal rulemaking process where all stakeholders can participate.

WSPA appreciates the opportunity to provide comments on this important regulatory process. If you have any questions regarding this submittal, please contact me at via email at tderivi@wspa.org.

Re: WSPA Comments on the Low Carbon Fuel Standard Modeling Updates Workshop

Dear Dr. Laskowski,

The Western States Petroleum Association (WSPA) appreciates the opportunity to provide these written comments on the California Air Resources Board's (CARB) August 16, 2023 public workshop regarding updates to the California Transportation Supply (CATS) Model used for the Low Carbon Fuel Standard (LCFS) program. WSPA is a trade association that represents companies that provide diverse sources of transportation energy throughout the west, including California. This includes the transport and marketing of petroleum, petroleum products, natural gas, renewable fuels, and other energy supplies.

Diesel Fuel Demand and Heavy-Duty Vehicle Zero Emission Vehicle (ZEV) Assumptions

While CARB has sought to update the CATS Model to account for the recent adoption of the Advanced Clean Fleets (ACF) regulation, WSPA appreciates the known transportation electrification-related uncertainties as identified in the 2022 Scoping Plan Update's "Uncertainty Analysis"[1] and the ACF regulation itself. These were recently discussed during CARB's new ACF "Truck Regulations Advisory Committee" on August 22, 2023 – where infrastructure challenges and vehicle readiness were amongst the priority issues identified by affected stakeholders that could affect compliance. We further note that the ACF regulation was only recently finalized and re-filed with the Office of Administrative Law for a final determination, so CARB has not yet submitted it to the U.S. Environmental Protection Agency for the required Clean Air Act waiver request that would make the regulation enforceable (if granted). Furthermore, we note that the North American Electric Reliability Corporation – the entity responsible for the reliable operation of our bulk power system – recently identified energy policy as the top risk – with grid transformation, resilience to extreme events, security risks, and critical infrastructure interdependencies falling behind – to the reliable operation of the Bulk Power System in their 2023 ERO Reliability Risk Priorities Report.[2] We again urge CARB to more closely evaluate what impact the large-scale shift of heavy-duty trucks would have on the energy demand of California's electric grid.

We would recommend that CARB not set LCFS benchmarks based on the presumed and wholly successful implementation of ACF given the significant known challenges identified to date and without also having an alternative pathway to ensure the reliable provision of necessary services to all Californians. Although CARB shows a 37% reduction of diesel fuel demand from 2022 to 2045 in the CATS Model updates, if medium- and heavy-duty ZEVs do not saturate the market as quickly as CARB assumes in staff's presentation (slides 17 and 18), likely resulting in prolonged and heightened demand for liquid fuels, transportation fuel companies will need a continuing means to comply with the LCFS regulation. We encourage CARB to conduct periodic reviews of

[1] Appendix J, https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-sp-appendix-j-uncertainty-analysis.pdf
[2] https://www.nerc.com/comm/RISC/Related%20Files%20DL/RISC_ERO_Priorities_Report_2023_Board_Approved_Aug_17_2023.pdf

the program, accounting for the real world implementation status of ACF, Advanced Clean Trucks, the Omnibus regulation, and include a flexible compliance mechanism to make adjustments accordingly.

CATS Technical Documentation – CI Factor Assumptions

Table 11[3] shows a significant reduction of the carbon intensity (CI) of the electric grid from 2044 to 2045 – from 48.3 (in 2044) to 16.5 (in 2045). WSPA seeks clarification from staff regarding the CI curve for the electricity grid, and confirmation that such a substantial CI reduction could take place in a single year.

WSPA appreciates the opportunity to provide comments on the CATS modeling updates. If you have any questions regarding this submittal, please contact me via email at tderivi@wspa.org.

Sincerely,

Tanya DeRivi

RE: Staff Draft Proposal on the Low Carbon Fuel Standard: Silicon Valley Leadership Group Comments

Dear Chair Randolph,

Thank you for the opportunity to comment on the staff draft proposal for the Low Carbon Fuel Standard (LCFS) rulemaking process.

Silicon Valley Leadership Group (SVLG), founded in 1978 by David Packard of Hewlett-Packard, represents hundreds of Silicon Valley's most respected employers on issues that affect the economic health and quality of life in Silicon Valley. Our membership includes many key players in this arena—from companies transitioning to electric vehicle (EV) fleets, to those producing zero-emission vehicles (ZEVs) and developing innovative new zero-emission technologies. At a high level, our organization believes CARB should employ flexible, market-based and technology-neutral policies that achieve maximum greenhouse gas (GHG) emissions reductions at the lowest cost.

We appreciate the Board and staff's diligence in drafting a thoughtful staff proposal for the Low Carbon Fuel Standard. However, we would urge a timely resolution to the rulemaking process to revitalize the LCFS credit market as soon as possible. Imbalances to the market caused by an overabundance of credits have tanked credit value, jeopardizing financing for clean energy projects and significantly diminishing the ability of the state to deploy zero-emission vehicles and charging infrastructure. This is no small problem for the state as regulators, advocates, and industry alike work to meet California's ambitious climate and air quality goals.

Our following comments reflect the changes SVLG would like to see made to the LCFS program.

Adopting an Acceleration Mechanism

SVLG thanks the Board and Staff for including an auto-acceleration mechanism to automatically increase carbon-intensity benchmarks when credit values fall too far and credits outnumber

242.1 deficits. However, SVLG requests that the auto-acceleration mechanism and its triggers be implemented as soon as possible without delay. An implementation date of 2026 would sooner protect the health of the market and provide much-needed assurance to industry stakeholders on credit value.

Infrastructure Capacity Credits:

SVLG appreciates the extension of infrastructure capacity crediting for light-duty vehicles (LDV). However, the reduction in available capacity credits for LDV fast charging infrastructure (FCI) from 2.5% to half a percent of deficits will significantly constrain the market opportunities for
242.2 deploying LDV FCI. SVLG would encourage the Board to maintain the capacity crediting cap for LDV FCI at 2.5%, which reflects increasing demand for light-duty zero-emission vehicles (ZEVs) and the need for refueling capacity across the state.

242.3 Additionally, SVLG supports the inclusion of capacity credits for medium- and heavy-duty zero emission vehicle fueling within LCFS. This new incentive program will be groundbreaking for encouraging the deployment of infrastructure needed to serve clean trucking fleets throughout the state as companies comply with the Advanced Clean Fleets rulemaking.

Third Party Verification Requirements:

242.4 SVLG is concerned that requiring site visits for third party verification of Fueling Supply Equipment for electricity pathways will pose an excessive and unnecessary burden on owners of both commercial and residential EV credit generators. EV charging infrastructure is both highly distributed by nature and subject to many state and federal standards ensuring accuracy. Quality data can already be provided remotely by EV service providers and through vehicle telematics. As California continues to develop a well-distributed and geographically diverse charging network, the challenge of conducting site visits will only grow. SVLG requests that the Board consider exempting electricity pathways from Fueling Supply Equipment site visits

Book-and-Claim Accounting for EV Charging: Parity between Energy Types

SVLG appreciates the flexibility created by allowing the quantity of EV charging provided by low carbon intensity (CI) electricity to be reported through book-and-claim accounting. To achieve parity between energy types and further encourage EV charging in a wider variety of geographic
242.5 areas, SVLG requests that the Board extend the ability to use book-and-claim accounting to

242.5 allow biomethane and renewable natural gas to be used by offsite systems generating electricity for EV charging services as well.

Obligating Jet Fuel

SVLG appreciates the Board's goal of reducing GHG emissions associated with air travel, and is supportive of increasing the production and use of sustainable aviation fuel (SAF). SAF is by far the most efficient alternative to jet fuel currently available, presenting an 80% reduction in lifecycle emissions in comparison. However, current in-state SAF production is insufficient to meet market need.

242.6 SVLG is concerned that obligating jet fuel under an LCFS pathway at this time would present enormous and excessive cost implications for all airlines and airports that operate in-state, without effectively supporting production of the tools and fuels needed to reduce emissions. In turn, these cost impacts would be felt by all consumers and businesses that rely on airline services for travel and commerce. SVLG encourages CARB to continue working with industry to instead develop an incentive-based framework to ramp up both production and use of SAF. This approach would be the most time-efficient and cost-effective way to support California's emission reduction goals without creating excessive costs impacts on consumers in and beyond California.

Summarizing Thoughts

California leads the nation in light-duty ZEV adoption, surpassing our goals of selling 1.5 million electric vehicles and installing 10,000 fast chargers ahead of schedule. Thanks to the Advanced Clean Fleets regulation, zero-emission medium- and heavy-duty trucks are not far behind. While SVLG has been proud to support the state and our diverse membership in achieving these goals, much more progress needs to be made to further reduce the GHG emissions and air pollution associated with transportation.

A robust LCFS program is essential for building the infrastructure necessary to support ZEV deployment, and is critical for meeting the targets outlined in the Board's 2022 Scoping Plan. SVLG welcomes the opportunity to partner with CARB to support a thriving Low Carbon Fuel Standard. We look forward to working with you further.

Sincerely,

Tim McRae

RE: Growth Energy Comments on Proposed LCFS Amendments

Chair Randolph:

Growth Energy appreciates the opportunity to provide comments to CARB regarding potential amendments to the Low Carbon Fuel Standard (LCFS) ("Proposed Amendments" or "Proposal"). Growth Energy is the world's largest association of biofuel producers, representing 97 U.S. plants that each year produce 9.5 billion gallons of renewable fuel; 115 businesses associated with the production process; and tens of thousands of biofuel supporters around the country. Together, we are working to bring better and more affordable choices at the fuel pump to consumers, improve air quality, and protect the environment for future generations. We remain committed to helping our country diversify its energy portfolio to grow more green energy jobs, decarbonize the nation's energy mix, sustain family farms, and drive down the costs of transportation fuels for consumers.

Growth Energy has previously submitted extensive comments demonstrating the vital role low carbon biofuels and higher biofuel blends can play in meeting California's ambitious climate goals. As we have previously noted, biofuels have been among the largest contributors to the success of the LCFS program to date and are poised to continue to do so with appropriate updates to the program.[1]

Unfortunately, the Proposal could impose new, costly, and unnecessary compliance burdens on bioethanol producers in the form of as-yet unknown and undefined "sustainability requirements"[2] that risk reducing the availability of credit-generating biofuels within the LCFS Program. Of most significant concern, contrary to the California Administrative Procedure Act (APA) and the California Environmental
243.1 Quality Act (CEQA), CARB is not providing the public and regulated community notice

[1] *Decarbonizing Combustion Vehicles,* Transportation Energy Institute (July 2023) https://www.transportationenergy.org/wp-content/uploads/2023/07/Decarbonizing-Combustion-Vehicles_FINAL.pdf
[2] Proposed 17 C.C.R § 95488.9(g).

243.1 and the opportunity to comment on the substance of these requirements. Rather, CARB intends to outsource development of these vague sustainability "certification systems" covering a host of undefined "environmental, social, and economic criteria" to third parties. The Proposal specifies that CARB alone will determine which certification systems suffice, removed from the California regulatory process intended to protect the public and regulated community and without consideration of potential adverse environmental impacts consistent with CEQA. Without any clear indication in the Proposal or voluminous rulemaking materials as to what such "certification systems" may entail, it is difficult to determine whether they may in practice, unintentionally or otherwise, exclude as much as 60% of the current credit-generating fuels from the
243.1 LCFS program. Such a reduction would create increased demand for fossil fuels, resulting in higher emissions of GHGs as well as toxic air pollutants.

If such "certification systems" did function in that manner, whether due to economic, social, or environmental criteria, the regulations could not comport with AB32's requirement for cost-effective, technology-neutral greenhouse gas (GHG) emissions reductions. For example, removal of even a portion of currently credit-generating biofuels could substantially increase compliance costs on obligated parties and passed-down costs to consumers at the pump, disproportionately harming low-income communities that are most impacted by fuel costs. None of these potential impacts have been adequately identified or evaluated in CARB's rulemaking materials accompanying the Proposal.

The proposed sustainability requirements are also legally flawed because they
243.2 are not reasonably necessary to effectuate AB32, or to address any regulatory purpose provided in CARB's rulemaking materials. Put simply, CARB has failed to identify any credible evidence of direct land use conversion that could be mitigated by some form of feedstock tracking based on social, economic, and environmental criteria of an unknown form and substance. As many decades of data has demonstrated, increases in bioethanol demand have consistently been met with increased yield per acre, not with increased corn acreage. Further, other regulatory mechanisms — including oversight from the U.S. Environmental Protection Agency (EPA) under the Renewable Fuel Standard (RFS) Program — adequately ensure that U.S. feedstocks are sustainably sourced and do not contribute to land use conversion. CARB itself also already imposes a highly conservative and overestimated penalty to the carbon intensity of bioethanol in the LCFS program that greatly disincentivizes bioethanol as compared to other fuel types. And CARB lacks authority under AB32 to, through a third-party certification system, impose wide-ranging socio-economic criteria that are unrelated to the cost-effective reduction of GHG emissions.

We understand that CARB is postponing the public hearing on the Proposed Amendments in order to undertake "more consideration of the proposed sustainability

guardrails, among other topics."[3] Growth Energy agrees such additional consideration is
necessary. Indeed, consistent with the California APA, if the Proposed Amendments
intend to encompass some form of feedstock tracking requirements tailored to address
243.3 a specific environmental need, we urge CARB to allow regulated parties to comment on
a subsequent proposal that includes consideration of potential environmental and
economic consequences.

In addition to these issues, the Proposed Amendments fail to include several key
updates and as a result, fall far short of unlocking the LCFS Program's full
243.4 decarbonizing potential. These omissions include declining to recognize and incentivize
low-carbon agricultural practices, failing to update emissions factors and lifecycle
modeling to reflect the best available science, and continuing to prohibit the use of E15
in the state.

We encourage CARB to reconsider these aspects of the Proposal to ensure the real and significant GHG emissions reductions benefits of biofuels are realized under the LCFS. We look forward to engaging collaboratively with the agency to support its efforts.

I. Bioethanol Has Been and Must Continue to Be a Key Driver of Transportation-Sector Emissions Reductions in California

The transportation sector is responsible for 39% of California GHG emissions — far larger than any other sector.[4] Light-duty vehicles (LDVs) alone emit more than any other entire sector, with over 27% of the state's total emissions.[5] Critically, over 97% of LDVs on the road in California today rely on liquid fuels.[6] On-the-road fleet turnover is a lengthy process, meaning impacts from California's 2035 zero-emission vehicle (ZEV) new vehicle sales requirements are still many years away.[7] To decarbonize the transportation sector today, California will need to decarbonize the liquid fuels being used by the vast majority of its vehicles by displacing fossil fuel consumption with low-carbon, renewable biofuels, including bioethanol.

Beyond LDVs, low-carbon biofuels will also play a substantial role in reducing emissions from harder-to-abate subsectors including medium- and heavy-duty vehicles, maritime fuels, and aviation. With lower ZEV adoption to date and longer fleet turnover

lead times, these subsectors are even more reliant on biofuels to achieve California's decarbonization goals.

Already, we've seen biofuels provide the foundation for the LCFS. In fact, biofuels like bioethanol have generated more than 75% of LCFS credits.[8] In 2022, domestically produced bioethanol made up ~50% of credit-generating biofuels by volume.[9] This group of fuels has been among the largest contributors to the success of
243.5 the LCFS Program to date, and will need to continue to be a central component of California's transportation sector decarbonization strategy if the LCFS is to continue its success into the future. Indeed, according to recent data from Environmental Health and Engineering, today's bioethanol reduces GHG emissions by nearly 50% compared to gasoline and can provide even further GHG reductions with additional readily available technologies.[10] For example, over a decade ago, CARB reported the average carbon intensity (CI) for bioethanol at 88 g/MJ. Through the third quarter of 2022, the average recorded CI for bioethanol decreased to 59.39 g/MJ, a 33% reduction in CI, even including overstatements in modeled indirect land use change emissions.[11]

The world is in a decisive decade to address GHG emissions while critical climate goals remain in reach, and biofuels have the greatest potential to reduce GHG emissions across the transportation sector this decade — while also achieving benefits for air quality through reductions in harmful particulates and air toxics, as discussed further below.

II. The Proposed Sustainability Certification Requirements for Biofuels are Legally Flawed

243.3

A. CARB Cannot Outsource Development of a Sustainability Certification System to Third Parties with No Meaningful Public Participation from the Regulated Community and No Notice as to What the Sustainability Criteria Will Be.

The California APA was designed both to "advance meaningful public participation in the rulemaking process" and "create an administrative record assuring effective judicial review."[12] Central to these goals is the principle of fair notice so the regulated community can understand, anticipate, and participate in the development of the legal requirements they will be subject to. As the California Supreme Court has

[11] Based on data available at LCFS Pathway Certified Carbon Intensities, https://ww2.arb.ca.gov/resources/documents/lcfs-pathway-certified-carbon-intensities.
[12] Voss v. Superior Ct., 46 Cal. App. 4th 900, 908, 54 Cal. Rptr. 2d 225, 229 (1996).

explained, the APA works "to ensure that those persons or entities whom a regulation will affect have a voice in its creation, as well as notice of the law's requirements so that they can conform their conduct accordingly."[13] To support fair notice, the APA mandates regulations be presented with sufficient clarity so as to be "easily understood by those persons directly affected by them."[14] A regulation is not presumed to comply with the clarity standard if it "can, on its face, be reasonably and logically interpreted to have more than one meaning" or "uses terms which do not have meanings generally familiar to those directly affected by the regulation, and those terms are defined neither in the regulation nor in the governing statute."[15]

The APA's collaborative public rulemaking process not only benefits the public and regulated community but CARB as well, since "the party subject to regulation is often in the best position, and has the greatest incentive, to inform the agency about possible unintended consequences of a proposed regulation."[16] The process also "directs the attention of agency policymakers to the public they serve, thus providing some security against bureaucratic tyranny."[17]

243.1 Here, the Proposed Amendments would remove all meaningful public participation by assigning to a third-party development of sweeping "certification systems" intended to determine which fuels are eligible and ineligible to generate credits under the program. The Proposal does not provide biofuels producers with any notice of what "environmental, social and economic criteria" will be included, how the producer might accomplish "demonstrable means of evaluation," or what "sanction mechanisms" could be levied for non-compliance. Each of these vague and open-ended terms is susceptible to many differing meanings and is not defined in either the regulation or the governing statute, therefore lacking the clarity required by the APA. Indeed, Appendix E, which purports to explain the purpose and rationale for specific regulatory provisions, suggests the certification standards will ensure biofuels are "sustainably produced," but nowhere does CARB define what that means or how a complex certification system encompassing wide-ranging social, economic, and environmental considerations would accomplish that end.[18]

Not only is the certification system still undefined today, CARB proposes that the system — which will have the power to potentially exclude the majority of the fuels currently generating credits in the LCFS — will be developed not through a CARB public rulemaking process, but rather by a third-party entity requiring only the sign-off of the

[18] Appendix E at 80.

CARB Executive Officer. This extremely broad delegation of authority to third parties outside the regulatory process is highly concerning.

More fundamentally, as detailed below, the overwhelming evidence does not support a need to institute a feedstock tracking system for U.S. bioethanol producers. However, to the extent CARB does intend to proceed with the development of feedstock tracking requirements tailored to ensuring land conversion is not occurring, it must develop those requirements itself, through public engagement and the APA rulemaking process. The agency cannot simply outsource a complex rulemaking process to third

243.1 parties, guided by only vague statements of "environmental, social, and economic criteria" without notice and opportunity for the regulated community to comment on the scope, form, or stringency of the future standards.[19] Absent an informed decision-making process, the "sustainability" certification systems may function to erroneously exclude low carbon fuels from the LCFS Program with dire consequences both for the Program and the environment. Because such requirements are yet unknown, CARB itself has not yet adequately analyzed the potentially complex environmental impacts of the Proposed Amendments, as explained further below.

B. CARB Has Not Identified a Reasonable Need to Impose Sustainability Requirements on U.S. Bioethanol Producers

As a threshold matter, under California law, "no regulation adopted is valid or effective unless consistent and not in conflict with the statute and reasonably necessary to effectuate the purpose of the statute."[20] California agencies must provide "[a]n initial statement of reasons for proposing the adoption, amendment, or repeal of a regulation," that must include, *inter alia*, (i) the specific purpose of the proposed rule, amendment, or repeal, (ii) the "rationale for the determination by the agency that each [rule] adoption, amendment, or repeal is reasonably necessary to carry out the purpose and address the problem for which it is proposed" and (iii) the benefits of the proposed rulemaking.[21]

243.2 Here, CARB has failed to adequately articulate a reasonable need for the proposed sustainability requirements.[22] These requirements risk undercutting the broader purpose of the 2024 Amendments to implement the 2022 Scoping Plan by reducing GHG emissions, do not serve any function not already addressed through other regulatory measures, and extend far beyond the scope of what is necessary to effectuate AB32.

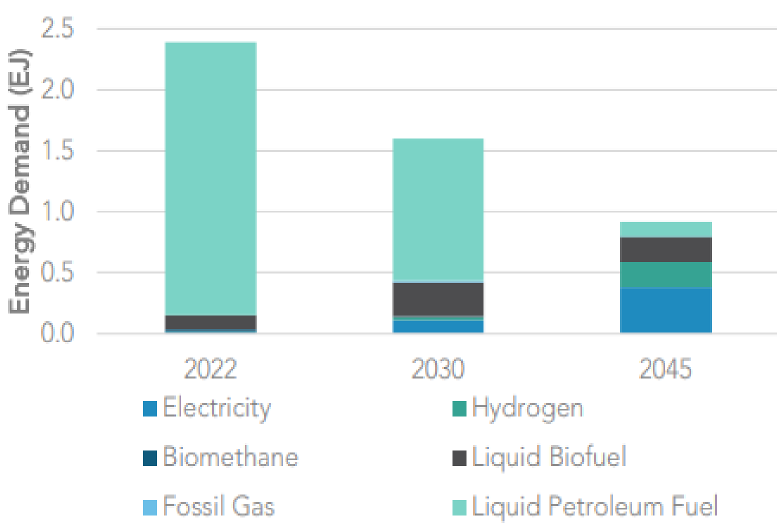
[22] *See* Light v. State Water Res. Control Bd., 226 Cal. App. 4th 1463, 1495 (2014) (noting that regulations may be declared invalid if the agency's determination of reasonable necessity is not supported by "substantial evidence").

243.6 1. The sustainability requirements risk undermining the overarching purpose of the 2024 Amendments and 2022 Scoping Plan

CARB's initial statement of reasons (ISOR) states that the Proposed Amendments are intended "to implement the 2022 Scoping Plan Update" by "reduc[ing] emissions by driving down fossil fuel demand in transportation, transitioning to zero-emission technology wherever feasible, and increasing the supply of low-carbon alternative fuels as quickly as possible."[23] The 2022 Scoping Plan calls for substantial ***increases*** in liquid biofuels between 2022 and 2030, with demand in 2045 still remaining higher than current levels. Bioethanol, which currently makes up half of the biofuel used in California, will need to remain a major fuel source if the increases called for in the Scoping Plan are to be achieved.[24]

Figure 4-2: Transportation fuel mix in 2022, 2030, and 2045 in the Scoping Plan Scenario[332]



The 2022 Scoping Plan calls for substantial increases to liquid biofuel demand. See 2022 Scoping Plan at 190.

The proposed sustainability requirements, however, could undermine this stated purpose by levying unnecessary and substantial compliance costs on certain biofuels, and risk excluding certain low carbon fuels altogether. The effect of which would be to reduce the volume of credit-generating biofuel available to displace fossil fuels in the California market. Indeed, CARB's own analysis in this rulemaking is clear that

---

[23] Proposed Low Carbon Fuel Standard Amendments, Staff Report: Initial Statement of Reasons (Dec. 19, 2023) at 22 [hereinafter "ISOR"].
[24] Based on 2022 gasoline-gallon-equivalent data available at LCFS Data Dashboard, Figure 10(a), https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard

limitations on biofuels like bioethanol can result in increased fossil fuel consumption and increased GHG emissions.[25] Although the sustainability requirements are not an established cap on crop-based biofuels volumes, the potential for increased costs and decreased availability of qualifying fuels would limit the LCFS Program's ability to meet its carbon-intensity reduction targets by arbitrarily excluding certain low carbon intensity fuels for unknown "social and economic" reasons.

The Scoping Plan does caution that a "dramatic increase in alternative fuel production must not come at the expense of global deforestation, unsustainable land conversion, or adverse food supply impacts."[26] Growth Energy agrees. But CARB has failed to identify any credible evidence that U.S. bioethanol production is contributing to global deforestation, unsustainable land conversion, or adverse food supply impacts and no such evidence exists. Nor has CARB adequately described how the certification systems oriented towards a range of economic, social, and environmental considerations would protect against such impacts if they were a valid concern. Moreover, this single precautionary sentence is not an authorization to disregard the Scoping Plan's central purpose of achieving GHG emissions reductions, driven in part by increasing biofuel consumption in the transportation fuel mix.

243.6 2. CARB has not identified any credible evidence that domestically produced bioethanol contributes to direct land use change

The proposed sustainability certification requirements are introduced as a method to address *direct* land use change (dLUC).[27] As the feedstock tracking requirements presumably would follow only those crops used to produce biofuels eventually used in the California market, they would not and could not address *indirect* land use change (iLUC), which is a modeled estimate of price-mediated global land use impacts attributable to demand increases, regardless of whether a particular crop makes its way to the California market or is used in biofuel production at all. As such, CARB's analysis of whether new regulations are "reasonably necessary" must address whether the sustainability requirements are reasonably necessary to protect against *direct* land use change. For U.S. corn starch bioethanol that answer is unequivocally no, as there is no evidence that U.S. bioethanol production contributes to direct land use change. CARB suggests that "the growing demand for crop- and forest-based feedstocks for use in the LCFS program produce an increasing risk of deforestation and use of land with a high biodiversity value to meet this demand."[28] But there simply is no factual support for that statement as applied to U.S. bioethanol.

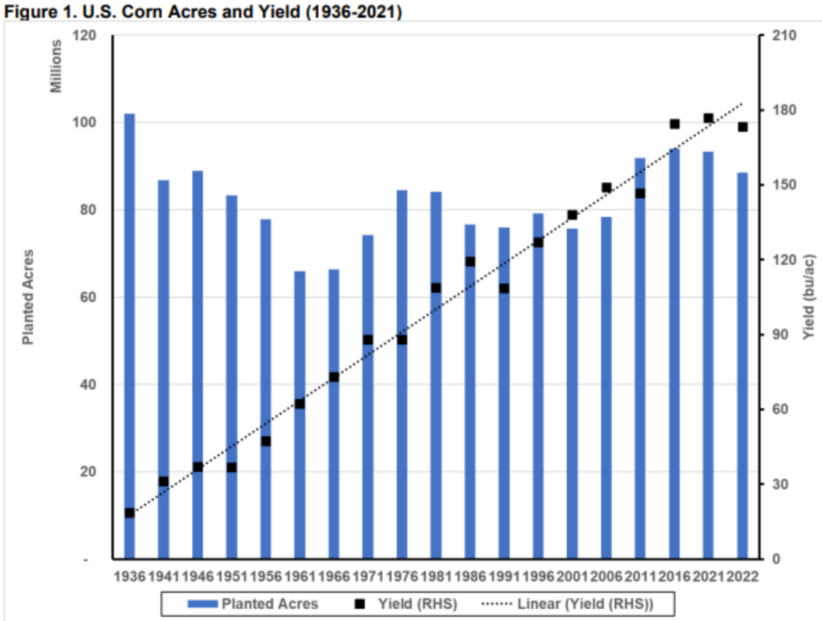
[27] ISOR at 32.
[28] Proposed Low Carbon Fuel Standard Amendments, Appendix E: Purpose and Rationale at 79-80.

Indeed, decades of empirical data from the U.S. Department of Agriculture (USDA) that EPA closely monitors as part of the federal RFS demonstrates that the amount of corn acres planted has remained stable over time even as bioethanol production has expanded by billions of gallons over the past 15 years. U.S. farmers have consistently met increased demand through increases to the amount of corn yielded per acre, rather than through expanding the acreage in production:

Figure 1. U.S. Corn Acres and Yield (1936-2021)



***Source**: USDA, Stillwater analysis*

Demand increases have been consistently met with increases in corn yield and the demand-offsetting effects of dry distillers grain solubles (DDGS), without any need for land extensification.[29]

Moreover, the RFS Program adds an additional layer of protection against cropland expansion by limiting eligible renewable fuels to those sourced from agricultural land that was cleared prior to 2007 in order to be eligible to generate credits under the program. To enforce this provision, U.S. EPA closely monitors aggregate cropland data in the United States to ensure that increases in biofuels demand do not result in increased cropland acreage. EPA may in the future determine that a feedstock tracking requirement is necessary if data shows that U.S. corn acreage begins to increase, but to date that agency has determined that it is unnecessary to do so given clear data indicating increased production absent land conversion. CARB's proposal to apply sustainability requirements to domestically produced bioethanol is therefore an unnecessary "solution" in search of a not-yet-existent problem. Further, the Proposed

[29] Stillwater Assoc., LLC, *Assessment of Production and Consumption Capacity of Conventional Ethanol in 2023-2025* (Feb. 9, 2023).

Amendment's scope strays widely from what would be necessary to address land use change, if there were in fact a problem to address.

With no evidence that corn acreage is increasing, the potentially substantial compliance costs of the proposed sustainability requirements are not reasonably necessary to address CARB's stated purpose. At a minimum, U.S. corn bioethanol producers should be excluded from the requirements due to the decades of evidence showing stable domestic corn acreage, as well as the existing oversight from U.S. EPA as part of the RFS Program. Socio-economic sustainability requirements are not reasonably necessary to effectuate cost-effective GHG reductions or address direct land use change.

AB32 designated CARB as the state agency charged with "monitoring and regulating the sources of emissions of greenhouse gasses" to further the statute's goal to "achieve the maximum technologically feasible and cost-effective greenhouse gas emission reductions."[30] While the agency may "consider overall societal benefits" when crafting its regulations,[31] AB32 does not endow CARB with broad authority to enact economic and social regulations that are untethered from cost-effective GHG emissions reductions. The Executive Order establishing the LCFS has a similarly discrete focus: "to reduce the carbon intensity of California's transportation fuels."[32]

CARB does not specify the certification requirements that will eventually be adopted, but the Proposed Amendments include a vague, far-reaching list of topics with no clear nexus to whether a feedstock originates on land placed into agricultural production prior to a certain date. For example, the contemplated feedstock certification program must address "social and economic criteria" and include "economic . . . and social stakeholders," but nowhere does CARB explain why a certification system must encompass such wide-ranging concepts to address the purported issue of land use change.[33] While CARB's proposal provides no detail as to what will actually be required of biofuel producers, it is difficult to conceive how these socio-economic standards could be crafted in a manner that would be reasonably necessary to reducing GHG reductions in a cost-effective manner. Moreover, it is unclear why CARB selected January 1, 2008 as the date by which agricultural land must have been put to such uses or how regulated parties will retroactively prove out feedstock eligibility when the certification systems eventually take effect in 2028. More fundamentally, it should not be left to regulated parties, the public, or the courts to guess as to how these requirements will be crafted — CARB must clearly state the rationale for its reasonably necessary determination in its statement of reasons.[34]

[30] Cal. Health and Safety Code § 38510; *Id*. at § 36569.
[31] *Id.* § 38562(b).
[32] Cal. Exec. Order S-01-07 (January 18, 2007).
[33] Proposed 17 C.C.R § 95488.9(g).
[34] Cal. Gov. Code § 11346.2(b).

243.6 3. Inconsistent with best available science, CARB's lifecycle emissions modeling tool already substantially over-penalizes bioethanol for modeled land use change impacts

The proposed sustainability requirements are also not reasonably necessary because CARB *already* "disincentivizes sourcing biofuel feedstocks from crops with higher land-use change risks" through application of an outdated and overly conservative estimated land use change penalty to bioethanol's carbon intensity.[35] CARB's analysis for this rulemaking acknowledges that "the likelihood of [direct and indirect land use change] is at least partially (**and potentially fully**) accounted for by the LUC scores added to crop-derived pathways."[36]

Specifically, CARB currently applies a LUC penalty of 19.8 gCO2e/MJ to U.S. corn starch bioethanol, derived from modeled estimates of iLUC.[37] However, through a multitude of refinements to model design and model inputs since CARB last updated its analysis in 2015, iLUC estimates for bioethanol have converged around a relatively narrow range that is substantially lower than CARB's estimate, even when differing models and differing model inputs are considered.[38] This cross-model convergence is observed in both American and European analyses, and is particularly highlighted by comparing studies which have published updates to their initial analysis using otherwise similar methodology. The most recent credible iLUC models have continued to adjust, refine, update, and calibrate their methodologies, resulting in a downward trend of estimates and convergence around -1.0 to 8.7 gCO2e/MJ.[39]

As discussed, CARB's proposed sustainability requirements would be ineffective at addressing iLUC, since the requirements apply only to crops physically used for biofuel feedstocks without consideration of global economic and land use patterns. However, to the extent that CARB's proposal is intended to disfavor crop-based biofuels within the LCFS program, CARB's inflated iLUC penalty already places a heavy finger on the scale to disincentivize such fuels.

C. The Proposal Will Lead to Increased Fossil Fuel Consumption Resulting in Increased Emissions of Toxic Air Pollutants in Violation of AB32

CARB may not undertake regulatory activities to reduce GHG emissions that interfere with federal or state efforts to reduce toxic air contaminant emissions in the

[35] ISOR at 32.
[36] EIA at 44 (emphasis added).
[37] 17 CCR § 95488.3 at Table 6.
[38] *See* Environmental Health and Engineering, *Response to Proposed Renewable Fuel Standard (RFS) Program Standards for 2023–2025*, Exhibit 2 of EPA-HQ-OAR-2021-0427-0796 (Feb. 10, 2023).
[39] *Id.*; Scully, et. al. *Carbon intensity of corn ethanol in the United States: state of the science*, 16 Environ. Res. Lett. 4 (2021).

state.[40] The proposed sustainability requirements may reduce the amount of renewable biofuel consumed in California by placing significant compliance costs on producers of bioethanol and decreasing the availability of credit-generating biofuels. As a direct result of reducing the available volumes of biofuel, fossil fuel consumption will increase. This boost in fossil fuel consumption would increase not only GHG emissions, but also emissions of several toxic air pollutants.

As CARB acknowledges in the ISOR, higher amounts of renewable fuel consumption lead to significant reductions of both NOx and $PM_{2.5}$ emissions.[41] A recent study conducted by the University of California, Riverside also found that greater use of bioethanol-blended fuels can reduce carbon monoxide, ozone, and primary PM levels relative to the use of gasoline-only fuels.[42]

In addition, bioethanol boosts octane in fuel without the harmful impacts of alternative octane-boosting fuel additives, including methyl tert-butyl ether (MTBE), lead, and aromatics (including benzene, toluene, ethylbenzene, and xylene). Indeed, the level of aromatics in fuel decreases by about 7% for every 10% by volume increase in bioethanol content.[43] Decreasing aromatics in fuel has direct impacts on tailpipe emissions, with higher-ethanol fuels resulting in lower emissions of particulate matter (PM), black carbon (BC), particle number (PN), benzene, toluene, ethylbenzene, m/p-xylene and o-xylene (BTEX), and 1-3 butadiene as compared to higher aromatic fuels. Bioethanol blends are particularly effective at reducing cold-start PM and VOC emissions, with a 15-18% decrease in PM emissions for each 10% increase in bioethanol content by volume.[44] Primary $PM_{2.5}$ emissions have substantial human health impacts and have been shown to disproportionately impact racial and ethnic minorities, which are often located in urban areas where cold-start conditions are most common.[45]

---

[40] Cal. Health & Safety Code § 38562(b)(4) (CARB must "[e]nsure that activities undertaken pursuant to the regulations complement, and do not interfere with, efforts to achieve and maintain federal and state ambient air quality standards and to reduce toxic air contaminant emissions.").

[41] ISOR at 127 (noting that NOx and PM2.5 reductions in the accelerated decarbonization alternative as compared to the proposal were "primarily due to higher amounts of renewable fuels used."); *see also* ISOR at 66.

[44] *Id.*

[45] Tessum, et al., *PM2.5 polluters disproportionately and systemically affect people of color in the United States*, Sci. Advances (2021) at 7, https://doi.org/10.1126/sciadv.abf4491; Colmer, et al., *Disparities in PM2.5 air pollution in the United States*, 369 Science 6503 (2020) at 575, https://doi.org/10.1126/science.aaz9353.

In short, the Proposal is legally deficient in failing to grapple with the fundamental issue that the sustainability certification requirements may be inconsistent with CARB's mandate to protect air quality while achieving cost-effective GHG emissions reductions. In addition to providing adequate notice to the regulated community of what the sustainability criteria will entail, CARB must disclose and carefully evaluate the air quality impacts of any such new requirements consistent with Health & Safety Code § 38562(b)(4).

D. The Proposed Rulemaking Package Fails to Identify and Consider Potential Economic and Environmental Justice Costs of the Sustainability Requirements

Throughout the rulemaking materials accompanying the Proposed Amendments, CARB's analysis systematically omits any evaluation of the potential impacts imposed by the applicability of new sustainability requirements in conjunction with tightening carbon intensity standards through 2045. Indeed, the sustainability requirements are so undefined that it is unlikely that CARB could estimate such potential impacts with any level of confidence. But that does not relieve CARB of its obligations under California law. If CARB is unable to properly identify and evaluate the impacts of the sustainability requirements, it cannot finalize those requirements as proposed.

243.7 1. CARB Fails to Adequately Identify Potential Economic Costs

For major regulations, the APA requires agencies to publish a standardized regulatory impact analysis that includes "all costs" of the regulation on businesses in California.[46] The scope of this analysis must encompass "each type of business subject to the relevant proposals"[47] and is intended to provide to the agency and the public the "tools to determine whether the regulatory proposal is an efficient and effective means of implementing the policy decisions enacted in statute or by other provisions of law in the least burdensome manner."[48] Further, AB32 requires that CARB consider costs to employ technology-neutral and cost-effective GHG emissions reductions approaches.[49]

Nowhere in CARB's economic analysis does the agency address the potential costs of the proposed sustainability requirements. These requirements create plainly foreseeable potential impacts in at least two ways. First, the requirements are very likely to impose direct compliance costs on biofuels producers. CARB clearly overlooks the entire set of compliance costs imposed on low-carbon biofuels producers by asserting

---

[46] Cal. Gov. Code § 11346.2(b)(2)(B); *Id.* at § 113463.3; 1 C.C.R. § 2000(e).
[47] *John R. Lawson Rock & Oil, Inc. v. State Air Resources Bd*., 20 Cal. App. 5th 77, 114 (Cal. App. 2018) (finding CARB's economic analysis violated the APA for failing to consider impacts on intrastate trucking).
[48] Cal. Gov. Code § 11346.3(e).
[49] Cal. Health & Safety Code § 38562

that the Proposal's cost increases will "fall exclusively on producers of high-carbon intensity fuels," and consumer costs passed through by high-carbon fuels producers.[50]

Second, depending on how the sustainability requirements are eventually developed, there is potential for substantial costs on fuel producers as well as consumers if a large volume of credit-generating biofuels is unable to meet the sustainability requirements due to social, economic, or other considerations. The magnitude of this potential cost is unknown because the stringency and practicality of the sustainability requirements remain entirely undefined. But with bioethanol and other crop-based biofuels accounting for the majority of fuel in the program, poorly crafted sustainability requirements could create enormous disruption to the LCFS market if all or most of these fuels shift from credit-generating to deficit-generating volumes. CARB's fundamental failure to acknowledge and evaluate this potential risk in its economic analyses is highly concerning and contrary to law. As such, CARB must address in its record for this rulemaking a wide variety of economic cost impacts it ignores in this Proposal.

We encourage CARB to fully identify and evaluate the economic costs of the Proposal once any "sustainability" requirements are clarified prior to finalizing this rule.

243.8 2. CARB Fails to Adequately Identify Potential Adverse Environmental Justice Impacts

CARB's environmental justice analysis suffers from similar and overlapping flaws as its economic analyses by failing to consider the potential impacts of the sustainability requirements. As discussed above, unworkable or overly stringent sustainability requirements would likely lead to a decrease in available credit-generating biofuels in the LCFS Program. This would increase compliance costs on deficit-generating fuels producers, who would then pass through those costs to consumers in the form of higher fuel costs. This risks disproportionately burdening lower-income communities which spend a higher relative portion of their income on fuel expenses and for whom new electric vehicles may remain out of reach.

In addition, if the sustainability requirements displace volumes of biofuels, these volumes will likely shift to increased fossil fuel consumption, with resulting adverse air quality impacts as discussed above in Section II (C). This increase in toxic air pollution risks disproportionately burdening frontline communities located near major transportation corridors and around airports and ports.

---

[50] Proposed Low Carbon Fuel Standard Amendments, Appendix C-1: Standardized Regulatory Impact Analysis at 57.

We encourage CARB to fully identify and evaluate the potential environmental justice impacts of the Proposal once any "sustainability" requirements are clarified prior to finalizing this rule.

III. The Draft Environmental Impact Analysis Fails to Comport with CEQA's Requirements

243.9

At its core, CEQA requires California agencies to inform decision makers and the public about the potential environmental impacts of proposed projects (including rulemakings), and to reduce adverse environmental impacts to the extent feasible. For the myriad reasons discussed above, the Proposed Amendments and the accompanying Draft Environmental Impact Analysis (EIA) fail to satisfy this requirement. Informed decision-making is infeasible where CARB has failed to elucidate the details of a critical component of the LCFS that may materially impact volumes and types of fuels within the California transportation fuel mix. In so doing, it impermissibly "deprive[s] decision makers and the public of substantial relevant information about the project's likely impacts."[51]

In particular, CEQA regulations require that a draft EIA include "[a] discussion and consideration of environmental impacts, adverse or beneficial."[52] Nowhere does the Draft EIA grapple with the complex potential GHG and air quality implications of the poorly circumscribed "sustainability criteria." Indeed, the Draft EIA misapprehends the Proposed Amendments' scope entirely. It conceptualizes the sustainability requirement as tied exclusively to environmental considerations, i.e., confirmation of feedstock point-of-origin and potential conversion of land for use as feedstock.[53] It fails to recognize the "social and economic" considerations relevant to obtaining a certification and, in turn, fails to evaluate whether those criteria may drive low carbon and environmentally beneficial fuels like bioethanol out of the program.

Moreover, the Draft EIA summarily rejects an alternative option that eliminates the crop-based fuels sustainability criteria on unrelated grounds.[54] Specifically, the Draft EIA establishes a strawman: an alternative that it asserts does not meet the objectives of the Proposed Amendments and therefore need not be explored consisting of, among other things, a very aggressive 40% carbon intensity reduction requirement by 2030 coupled with no sustainability criteria. Without explanation, the Draft EIA claims this scenario "increases the risk of greater environmental impacts" without elaborating how specifically the sustainability criteria would function to abate impacts of concern, and why there may be environmental *benefits* to exclusion of such criteria.

---

[51] *Ctr. for Biological Diversity v. Dep't of Fish & Wildlife*, 62 Cal. 4th 204, 228, 361 P.3d 342, 356 (2015), as modified on denial of reh'g (Feb. 17, 2016).
[52] 17 C.C.R. § 60004.2.
[53] Draft EIA at 20 (emphasis added).
[54] *Id.* at 179.

Nor does the Draft EIA address why exclusion of the sustainability requirements is a relevant alternative scenario in only one of the multiple options evaluated. In accordance with California regulation, "[t]he range of feasible alternatives [must] be selected and discussed in a manner to foster meaningful public participation and informed decision making."[55] Prior to finalizing the Proposed Amendments and EIA, CARB must further define the sustainability criteria, allow regulated parties and the public to comment on the requirements' potential details and potential implications, and address any such comments regarding adverse environmental impacts that may follow from finalization of the requirements.

IV. CARB Should Use the 2024 Amendments to Accelerate Decarbonization

Despite the urgent need to address climate change and reduce GHG emissions from California's highest-emitting sector, CARB declined to adopt an "Accelerated Decarbonization" scenario that could have maximized the GHG-benefits of the LCFS Program. We urge CARB to reconsider several specific components of that proposal for inclusion in its final rule, as well as to update its lifecycle analysis for corn starch bioethanol to incorporate the best available science.

243.4 ### *A. CARB Should Recognize and Incentivize Low-Carbon Agricultural Practices*

Growth Energy strongly supports the appropriate crediting of on-the-farm low-carbon agricultural practices in the LCFS. As the Scoping Plan recognizes, climate-smart practices have "significant potential" to increase soil carbon storage and reduce GHG emissions, with important social and environmental co-benefits including in public health, water quality, water availability, and biodiversity.[56]

The ISOR states that consideration of low-carbon agricultural practices was rejected because "there is not yet a mechanism within the LCFS for quantifying, verifying, and including greenhouse gas emissions reductions or soil-carbon sequestration from changes in individual farm-level management practices in LCFS fuel pathways."[57] But there are more than enough tools and systems available to CARB to create such a mechanism, including the GREET FD-CIC model from U.S. Department of Energy's (DOE's) Argonne Laboratory, as well as USDA national standards for climate-smart agriculture. Specifically:

- *Use of cover crops*. Use of cover crops improves soil health and enhances soil organic carbon (SOC) sequestration. By sequestering atmospheric carbon dioxide in the soil, such use of cover crops offsets other carbon dioxide emissions from feedstock production, and lowers the lifecycle GHG emissions of

[55] 14 C.C.R. § 15126.6(f).
[56] 2022 Scoping Plan at 254.
[57] ISOR at 125.

bioethanol produced from corn feedstock grown using this method. USDA currently offers cover crop initiatives as part of its climate smart agriculture programs and has issued national conservation practice standards to define the practice.[58]

- *Effect of tillage*. Another method to enhance SOC sequestration is switching to no-till or reduced-till practices. Reduced disturbance of the soil supports greater sequestration of atmospheric carbon dioxide. USDA has also issued national conservation practice standards for both no-till and reduced-till agriculture.[59]

- *Manure application.* Application of agricultural byproducts and waste products such as manure can materially increase SOC sequestration. GREET's FD-CIC model can calculate changes in SOC emissions resulting from the use of swine, dairy cow, beef cattle, or chicken manure.

- *Improved fertilizer practices.* Precision application of fertilizer through "4R" techniques (right time, right place, right form, right rate) can significantly reduce emissions attributable to fertilizer usage. Similarly, applying bio-based fertilizers to corn, such as nitrogen-fixing biological products, legumes, or manure can significantly reduce the need for conventional fertilizer, providing a lower carbon-intensive source of fertilizer for the corn. In addition, nitrogen stabilizers can reduce the loss of nitrogen into the environment. This often leads to a reduced application rate of fertilizer, further reducing its environmental impact.[60]

- *Green or low-carbon ammonia.* Ammonia used to make fertilizer can be produced using renewable energy (where hydrogen from electrolysis of water reacts with atmospheric nitrogen) or with carbon-reducing technologies, reducing lifecycle GHG for producing corn feedstock to bioethanol production.[61]

There has been a wealth of data on the substantial benefits of these and other low-carbon agricultural practices, including a recent study by Argonne National Laboratory showing the possibility of a 35% reduction in carbon intensity through

[58] USDA Press Release No. 0005.22, *USDA Offers Expanded Conservation Program Opportunities to Support Climate Smart Agriculture in 2022* (Jan. 10, 2022); USDA Conservation Practice Standard # 340, Cover Crop (Ac.) (Sep. 2014).
[59] USDA Conservation Practice Standard # 329, *Residue and Tillage Management, No Till (Ac.)* (Sep. 2016); USDA Conservation Practice Standard # 345, *Residue and Tillage Management, No Till* (Ac.) (Sep. 2016).
[60] GHG reductions from precision application of fertilizer and use of nitrogen stabilizers are available from standard values in GREET's FD-CIC module. GHG reductions from bio-based fertilizer can be calculated based on farming inputs.
[61] GHG reductions from green ammonia are available from standard values in GREET's FD-CIC module. GHG reductions for low carbon ammonia can be calculated based on the ammonia production process.

adoption of current best on-farm practices.[62] With the LCFS' verification requirements, capturing these on-the-farm benefits for biofuel pathways is now more realistic and scalable. To the extent that CARB decides to implement additional verification requirements in the form of the proposed sustainability requirements, it would be especially arbitrary to simultaneously disallow credit-generation of verifiable low-carbon agricultural practices. Appropriately crediting climate smart ag will help biofuels producers continue to further innovate and lower their carbon intensity, while providing key incentives for farmers to adopt these effective conservation practices.

243.10 *B. CARB Should Update Its Lifecycle Analysis for Bioethanol to Incorporate the Best Available Science*

As discussed above in Section II(A)(3), CARB's current lifecycle analysis for U.S. corn starch bioethanol is outdated and a substantial overestimate as compared to the best available science. This overestimate is driven by an inflated iLUC penalty, which CARB has not updated since 2013-2015. Unlike CARB's iLUC estimate, the science of lifecycle emissions modeling has not remained stagnant over the past decade. Instead, through various improvements to both models themselves and the data models rely on, iLUC modeling has improved significantly in recent years with a clear downward trend converging around iLUC values that are less than half of CARB's current estimate.

This trend is made most obvious by comparing studies from the same authors that have updated their work. For example, EPA initially estimated in 2009 iLUC associated with ethanol that was more than double the value it ultimately incorporated into its final rule establishing the 2010 Renewable Fuel Standard.[63] More recently, studies from Taheripour, et al. demonstrated that using an updated land use module in GTAP-BIO resulted in iLUC estimates one-third to one-half of the magnitude of estimates using an outdated land use module within the same model.[64]

One key input in iLUC modeling where CARB's current methodology is particularly outdated is CARB's choice of emissions factors. Estimates of iLUC are the result of multiplying the acres of land that a model projects will be converted from various existing land uses to crop production (in order to meet a perceived increase in biofuel demand) by the additional GHG emissions that are attributable to that land conversion. The second input in this equation, estimating the GHG emissions attributable to each acre of land conversion, is referred to as the "emissions factor." Emissions factors vary based on the type of land converted. For example, converting forestland to cropland has greater GHG emissions than converting pastureland to cropland. Emissions factors are built on a multitude of assumptions relating to carbon

---

[62] Liu, et. al., *Shifting agricultural practices to produce sustainable, low carbon intensity feedstocks for biofuel production*, 15 Environ. Res. Lett. 8 (2020).
[63] *See* Environmental Health and Engineering, *Response to Proposed Renewable Fuel Standard (RFS) Program Standards for 2023–2025*, Exhibit 2 of EPA-HQ-OAR-2021-0427-0796 (Feb. 10, 2023).
[64] *Id.*

stocks of particular land types, including both above ground carbon (i.e., in trees or vegetation) and below ground carbon (including soil organic carbon). The choice of emissions factor that a model applies can have a significant impact on iLUC estimates.[65]

CARB's current iLUC modeling is based on the AEZ-EF emissions factors. Argonne National Laboratory — the authors of the GREET model that CARB incorporates for non-iLUC aspects of lifecycle emissions modeling — instead utilizes the CENTURY and Winrock emissions factors as part of the Carbon Calculator for Land Use Change from Biofuels (CCLUB). The CCLUB emissions factors are more scientifically defensible than AEZ-EF for multiple reasons. For one, CCLUB is updated by Argonne regularly to improve its estimates as the best available science develops.[66] In contrast, AEZ-EF was created for a particular modeling exercise completed to develop CARB's iLUC estimate in 2014, and has not been updated in the decade since, notwithstanding significant refinements in understandings regarding critical inputs like SOC estimates.[67] By its authors' own admission, AEZ-EF "relies heavily on IPCC greenhouse gas inventory methods and default values" from **2006**.[68] CCLUB also incorporates U.S. soil organic carbon estimates rather than relying on outdated international defaults,[69] and CCLUB's treatment of cropland pasture — one type of land that could potentially be converted for cropland — is informed by empirical data from USDA. This makes CCLUB more evidence-based than AEZ-EF, which simply assumes that converting cropland pasture to cropland releases 50% of the emissions associated with converting pasture to cropland. In addition, CCLUB accounts for a broad range of soil, climate, and management conditions, which "is consistent with the technique of the Intergovernmental Panel on Climate Change of continuously updating carbon stock change factors based on such factors as management activities and various yield scenarios."[70]

Further, empirical data show that iLUC is far lower than the range predicted by agro-economic models from more than a decade ago and is substantially overstated in those models. A recent International Energy Agency report, for example, evaluated real-world data from 2005-2015 and found "no link" between increased U.S. biofuel

[68] Plevin, et. al, *Agro-ecological Zone Emission Factor Model* (Sep. 2011).
[69] *Cf.* Kwon, et al. (2021) at 8 (describing CCLUB approach to modeling soil organic carbon changes in the U.S.; Plevin, et. al. (2014) at Table 20 (citing IPCC defaults).
[70] Taheripour et al. *Response to "how robust are reductions in modeled estimates from GTAP-BIO of the indirect land use change induced by conventional biofuels?"* 310 Journal of Cleaner Production 127,431 (2021).

production and corn production or deforestation in Brazil.[71] Instead, the report casts doubt on any causal relationship between biofuel production and corn prices or animal production.[72]

Ample scientific evidence currently exists for CARB to promulgate an updated LUC value for bioethanol that is consistent with the reduced range of iLUC values observed across the recent scientific literature. Growth Energy has submitted an abundance of evidence in both state and federal rulemakings to demonstrate the current state of the science, and we would be happy to work with CARB to address any outstanding concerns that may be delaying a much-needed update to CARB's lifecycle analysis.

243.11 *C. CARB Should Take Concrete Steps to Allow the Use of E15 Fuel in California*

We continue to urge CARB to expedite its approval of E15 fuel. E15, a blend consisting of 15% bioethanol, has been approved for use by the EPA in all passenger vehicles model year 2001 and newer — more than 96% of the vehicles on the road today — and is now for sale at more than 3,400 locations in 31 states. It is striking that in the state with the most aggressive climate policy in the country, the lowest carbon intensity gasoline product on the market (E15), remains unavailable to consumers and as a compliance tool for parties obligated to reduce the greenhouse gas emissions of California transportation fuel under the LCFS. In addition to its climate benefits through displacing more fossil fuel, E15 also provides substantial public health benefits through the reduction of criteria air pollutants, particularly $PM_{2.5}$ as discussed above. And E15 provides substantial cost benefits as well, selling for 15 cents less per gallon on average this summer where it was available. In certain states, these cost savings reached as high 60 cents per gallon. Many of these benefits are especially impactful to communities that are disproportionately overburdened by pollution, including urban communities in close proximity to highways and vehicular traffic, and low-income communities for which fuel costs make up a higher proportion of household expenditures.

We appreciate the Multimedia Working Group's continued work on the multi-media evaluation of E15, and we strongly encourage CARB to make material commitments towards expediting the approval of E15 for California consumers and to help drive immediate GHG reductions.

243.12 *D. CARB Should Allow Biofuel Producers to Access Crediting for Low-CI Power*

[71] *Towards an improved assessment of indirect land-use change*, IEA Bioenergy (Oct. 2022), https://task43.ieabioenergy.com/wp-content/uploads/sites/11/2022/10/IEA-Bioenergy-iLUCreport_Final.pdf.

[72] *Id.*

The Proposal also fails to recognize the carbon-reduction potential in crediting low-CI power sourcing in the production of biofuels, reserving this crediting mechanism solely for hydrogen used as a transportation fuel. This narrow provision provides no satisfactory justification, instead citing faulty arguments about resource shuffling and restricting low-CI power for other sources if the provision is expanded. Firstly, the Proposal fails the LCFS' fundamental policy goal of reducing carbon intensity in transportation fuels used in California. Allowing bioethanol producers to source *new* contracted low-CI power that is not included in a utility resource plan via a power purchase agreement does not impact electricity demand. Secondly, biofuels production occurs largely outside of California, in other electricity markets. Not only does this render the resource shuffling argument moot, but it also denies California the opportunity to lead other jurisdictions towards low-CI power capability.

243.13 *E. Accelerating the Use of Sustainable Aviation Fuel (SAF)*

As producers of one of the most scalable feedstocks for SAF production, we appreciate the Board's attention to development of this key market through its proposal to remove the exemption for intrastate jet fuel. We encourage CARB to continue to work with SAF producers, biofuel feedstock producers, and airlines to continue to seek ways to accelerate use of these important fuels to help decarbonize the aviation sector.

V. Conclusion

Thank you for the opportunity to provide input on the 2024 LCFS Amendments. The LCFS Program is a critical tool to addressing climate change, and we look forward to working with CARB to ensure the role of biofuels in making California's fuel mix more sustainable and help the state achieve its progressive climate goals through the expanded use of bioethanol.

Sincerely,

Christopher P. Bliley
Senior Vice President of Regulatory Affairs
Growth Energy

Sacramento, CA 95814

Re: Comments for Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments (lcfs2024)

Missouri Rural Crisis Center appreciates the opportunity to offer these comments to the California Air Resources Board (CARB) for the "Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments (lcfs2024)".

Missouri Rural Crisis Center is a nearly 40-year old statewide farm and rural membership organization representing thousands of farm families in hundreds of rural communities. Our mission is *to preserve family farms, promote stewardship of the land and environmental integrity and strive for economic and social justice by building unity and mutual understanding among diverse groups, both rural and urban*.

We previously submitted comments in January 2022, following a December 2021 workshop regarding the Low Carbon Fuel Standard and urged CARB to grant the "Petition for Rulemaking to Exclude All Fuels Derived from Biomethane from Dairy and Swine Manure from the Low Carbon Fuel Standard" and initiate an immediate rulemaking to restore integrity to the LCFS.

We also submitted comments in April 2022 for the March 29, 2022 "Workshop on Methane, Dairies and Livestock, and Renewable Natural Gas in California".

Because it's illogical, counterintuitive and harmful, we continue to oppose corporate factory farm gas as a
244.1 solution to climate change, and we vehemently support LCFS amendments to exclude all fuels derived from dairy and swine factory farm gas from the Low Carbon Fuel Standard.

CARB should not continue to implement a bad and misguided proposal that would allow corporate factory farm dairy and hog operations (anywhere in the country) to sell the methane created in their operations into this system. Specifically, including factory farm gas as a "solution" toward your Low Carbon Fuel Standard Goals would:

- Incentivize more corporate factory farms, harming family farmers, rural communities, and our environment, including increased water and air pollution.
- Create more corporate consolidation in the U.S. livestock industry.
- Commoditize methane production, which would fuel more methane producing practices, creating more destructive greenhouse gases.
- Create additional overproduction of commodities, pork and milk, increasing supply and further pushing down market prices paid to independent family farms.
- Pay foreign multinational meatpackers, like Chinese-owned Smithfield and Brazilian-owned JBS, for their pollution.

- Create incentives for the public (taxpayer dollars through government subsidies) to fund anaerobic digesters to capture factory farm gas.

On behalf of our 5,000+ members, we ask that you reform this pollution trading scheme that inflicts harm on our communities. We urge you to reform the LCFS to exclude all fuels derived from factory farm gas.

Thank you for your time and please let me know if you have any questions.

Sincerely.

Dairy Cares Technical Comments on the Proposed
Low Carbon Fuel Standard Amendments

February 20, 2024

Dairy Cares[1] appreciates the opportunity to provide these comments on the California Air Resources Board's ("CARB") proposed Low Carbon Fuel Standard ("LCFS") amendments ("Amendments"). Dairy Cares represents the California dairy sector, including dairy producer organizations, leading cooperatives, and major dairy processors. We appreciate CARB's efforts to lead a robust stakeholder process and its efforts to prepare a voluminous record in support of the proposed revisions to the LCFS. These comments focus on the biomethane crediting provisions. Our comments are summarized as follows:

245.1
1. Dairy Cares is broadly supportive of the proposed amendments, including updates to the environmental targets and alignment with Short Lived Climate Pollutant ("SLCP") reduction laws.

245.2
2. The Amendments impose an overly-broad phase-out timeline for biomethane crediting. CARB should revise these requirements and retain discretion to align implementation of crediting pathways under the LCFS with its statutory obligations under SB 1383.

DISCUSSION

1. Ongoing Crediting for Anaerobic Digester Projects Is Necessary to Meet the Statutory Requirements of SB 1383.

Greenhouse gas ("GHG") emissions are global pollutants, and it is important for CARB to demonstrate that its programs can harmonize environmental goals and protect the state's economy, consistent with the statutory requirements for the LCFS. Section 38560 of the California Health and Safety Code directs CARB to adopt regulations that achieve the "maximum technologically feasible and cost-effective" greenhouse emission reductions. Consistent with these requirements and the regulatory programs adopted to date, California's dairy farming families clearly recognize the importance of reducing GHG emissions and are

[1] For more information about Dairy Cares, please visit www.dairycares.com.

striving to advance many new in-state projects that reduce potent SLCP emissions. These projects are attributable to the signals provided by the LCFS. As a result of this important program, dairy farmers are able to reduce emissions and enhance the environment and economic stability of their farms. The LCFS plays a key role in justifying the investments needed to achieve SLCP reductions. In the face of anti-dairy activism, we greatly appreciate CARB's ongoing efforts to analyze factual evidence and understand the importance of voluntary programs like the LCFS to achieving the statutory mandates under SB 1383.

The LCFS is part of a comprehensive strategy for all types of GHG reductions, and the proposed Amendments follow through on CARB's previously stated intention to create a comprehensive plan to reduce SLCP emissions. We applaud CARB for its leadership and understanding the potential for California's bold action to have far-reaching impacts on a global scale:

> By developing a comprehensive plan to achieve necessary SLCP emission reductions in an effective and beneficial way, California can foster broader action beyond its borders and demonstrate effective processes and strategies to address climate change.[2]

The agency's 2022 Scoping Plan Update correctly recognized that, given the urgency of climate change and avoiding climate tipping points as identified in the recent Intergovernmental Panel on Climate Change assessment, efforts to reduce SLCPs are especially important right now.[3] The 2022 Scoping Plan Update accounted for the full 40% reduction in SLCPs by 2030, to achieve the overall reductions in GHGs by 2030 sought by the Plan. The 2022 Scoping Plan Update identified that "[i]nstall[ing] state of the art anaerobic digesters that maximize air and water quality protection, maximize biomethane capture, and direct biomethane to sectors that are hard to decarbonize or as a feedstock for energy" as a key strategy for successfully achieving reductions in dairy and livestock methane.[4]

Since then, it has become increasingly clear that global demand for dairy and meat is expected to increase significantly in the coming years. According to an analysis recently published by the Food and Agriculture Organization of the United Nations, by 2050, the growing and more affluent global population is anticipated to drive a 20 percent increase in animal

product demand for animal products [sic] compared to 2020 levels. Without intervention, this upward trend could result in increased emissions from livestock systems, potentially undermining efforts to reduce GHG emissions and exacerbating global temperature rises.[5]

CARB has extensively evaluated the role the LCFS plays in California's ability to achieve the SLCP reductions called for in Senate Bill ("SB") 1383, and the findings have consistently supported CARB's own conclusion that "the LCFS facilitates significant private investment in technologies that provide the methane reductions from dairy, livestock manure, organic waste, and landfill management operations called for by SB 1383."[6] The productive use of dairy biomethane is the primary strategy that is reducing SLCP emissions, as required by SB 1383..

Arguments that the LCFS will directly lead to larger dairy herd populations should be
245.3 rejected. Allegations of incentives to increase herds solely due to the LCFS are unsupported. In fact, reductions in total herd size continue to occur. This is especially apparent in Tulare County, which is the largest dairy producing county in the nation and location of many of the dairy digester projects that have already contributed to considerable methane reductions in California. A March 2023 report produced by Tulare County shows that milk cow populations in Tulare County decreased by nearly 15% during the same period that 39 digester projects began operations and another 13 were in planning and development.[7] Tulare County reported significant emission reductions during this same timeframe, making clear that, in Tulare County, the presence of LCFS incentives clearly did not increase total herd populations or otherwise alter the ongoing trend of herd reductions and consolidation in California's dairy industry.

Unfortunately, anti-dairy activists continue their misguided efforts to call for a complete change of course on the State's SLCP Reduction goals. Some have called for forced conversion to pasture-based operations, direct regulation of dairy farms, and immediate phase outs of dairy
245.4 digester incentives. These proposals will not only fail to achieve the desired greenhouse gas emission reductions but will also exacerbate the problem by causing significant emissions "leakage." Command and control measures for SLCP reductions in the dairy industry will accelerate dairies leaving California for states with less costly regulations and less commitment to climate protection. This outcome would be in direct conflict with CARB's mandates to minimize emission leakage in the design of its GHG programs. CARB has wisely rejected calls for immediate phase out of dairy biomethane pathways. We applaud CARB for developing a robust record on the importance of the LCFS to the achievement of SLCP emission reductions.

[7] Tulare County Annual Report of Dairy and Feedlot GHG Emissions in 2021 (March 2023) p. 8, available at: https://tularecounty.ca.gov/rma/permits/dairy/bos-agenda-item-2022-annual-report-of-total-ghg-emissions-from-dairies-feedlots-for-2021/.

245.2 **2. <u>CARB Should Not Create A Blanket 2040 Phaseout for In-state Dairy Fuel Pathways.</u>**

The Initial Statement of Reason ("ISOR") discusses the role of pipeline biomethane and that in the longer term, the State plans to shift away from biomethane as a transportation fuel source.[8] According to the ISOR, "this resource should be transitioned to other sectors. … in the long term, the existing market signals will need to transition accordingly to avoid stranded assets and the closure of methane capture projects."[9] The Amendments would phase out CNG pathways after December 31, 2040 and biomethane - hydrogen-based pathways would be phased out after December 31, 2045.

The ISOR does not identify what exactly the long-term tool will be once these phase-out dates take effect. Similarly, the ISOR does not address how, if at all, the Amendments would continue to support SLCP reductions after the phase out. We are concerned that in the absence of an ongoing financial signal, there could be project failure, which would risk increasing SLCP emissions. Smaller projects that naturally have longer pay-back periods (i.e., due to economies of scale in digester development), may not be undertaken at all. This is possible, particularly in light of the fact that in the period of 2025-30, out-of-state dairy projects will enjoy a permanent exemption from the new deliverability requirements, so long as the developer breaks ground before 2030. We are concerned that project developers will focus their efforts on locking in incentives for out-of-state projects, while smaller in-state projects are overlooked and face relatively short financial pay-back periods. There is important hydrogen-related fuel development occurring in the dairy sector that we are hopeful will qualify these concerns, but based on what we know now, more must be done to support SLCP reductions at smaller in-state dairies.

For this rulemaking, CARB should supplement the record and address how it will ensure that in-state dairies have access to financial capital needed to make long-term investments. CARB should qualify the uniform application of the proposed phase-out dates for biomethane pathways. The Tier 2 pathway application process should provide an opportunity to address unique circumstances, particularly those of smaller dairies that may require longer crediting periods to attract financing. Dairy Cares urges CARB to take a more nuanced approach and allow projects that will reduce emissions sources covered by SB 1383 to request an extension to the phaseout timelines through the tier 2 pathway application process.

CONCLUSION

Dairy Cares appreciates the opportunity to comment on this rulemaking and looks forward to continuing to partner with CARB and other stakeholders on the implementation of the Amendments and the successful achievement of the State's climate goals.

---

[8] *Id.*, p. 30.

[9] Id.

CARB and other leading climate researchers have concluded that dairy digester development is a necessity if the State has any hope of fulfilling its role as a world leader in the climate community. The need is acute for CARB to demonstrate to California dairy farmers that there are viable tools and long-term financial markets available for them to justify investing in long-term emission reduction solutions at their farms. This is particularly true now that LCFS prices have declined in recent years. The 2022 Scoping Plan Update provides guidance to CARB and other responsible agencies on how individual regulatory programs, such as the LCFS, are needed to ensure that the State's programs, such as the SLCP Plan, collectively achieve the emission reduction targets. Market mechanisms such as the LCFS are incredibly important to successfully protect SLCP project financing. The bottom line is that without markets for beneficial use of captured biomethane, projects will not be financed and built.

Dairy Cares encourages CARB to continue setting an example for the rest of the country by following the SLCP reduction guidelines established in SB 1383. The statute is clear in its direction to minimize leakage, and other states certainly will not follow California's lead if heavy-handed direct regulatory action is taken that causes dairy farmers to lose confidence in the program. Concern for direct regulation could lead to businesses leaving the state, increasing emissions elsewhere. This result is not only at odds with California's requirements for minimizing leakage pursuant to Assembly Bill 32, but also with the achievement of the SB 1383 targets and the state's overall climate goals.

Bioenergy Association of California

February 20, 2024

The Honorable Steven S. Cliff
Executive Officer
California Air Resources Board
Sacramento, CA 95814

Re: <u>Proposed Amendments to the Low Carbon Fuel Standard Regulation</u>

Dear Executive Officer Cliff:

I am writing on behalf of the Bioenergy Association of California (BAC) to comment on the 45-day language to amend the Low Carbon Fuel Standard regulations, which was released in early January. BAC strongly supports the increased stringency of the proposed regulation, but is very concerned about the continued use of Book and Claim for undelivered biomethane and the phase-out of avoided methane credits. Failing to require delivery of biomethane means that California will continue to use fossil gas on
246.1 the road and it will hurt instate projects that are converting organic waste to energy to meet the state's Short-Lived Climate Pollutant reduction, landfill diversion, wildfire reduction, and other important state policies. Phasing out credit for avoided methane emissions, even when they are not required by law, will also undermine efforts to meet the SLCP reduction requirements of SB 1383. BAC urges the Air Board, therefore, to revise the amendments to require biomethane delivery consistent with RPS and SB 1440, and to only phase out avoided methane emissions to the extent that they are required by law.

BAC represents more than 100 public agencies, private companies, and non-profit organizations working to convert organic waste to energy. BAC's public sector members include cities and counties, Tribes, local air districts, environmental and solid waste agencies, wastewater treatment facilities, public research institutions, community and environmental groups, and a publicly owned utility. BAC's private sector members include bioenergy project developers, technology providers, investors, an investor owned utility, waste haulers, food processing and agricultural companies, and more.

BAC members are currently producing the lowest carbon fuels in the LCFS program, including biomethane, electricity and hydrogen generated from dairy manure, diverted organic waste, landfill and wastewater biogas. Other BAC members are developing projects to convert forest and agricultural waste to low carbon and carbon negative fuels.

BAC's comments focus on the 45-day language regarding Book and Claim for undelivered biomethane and the phaseout of avoided methane emissions even where they are not required by law or higher emitting alternatives are allowed.

A. BOOK AND CLAIM SHOULD BE PHASED OUT CONSISTENT WITH THE RPS AND SB 1440.

BAC urges the Air Board to go back to the staff recommendations in 2022 and 2023 that would have phased out undelivered biomethane consistent with the RPS and SB 1440. This is critical for several reasons, described below. At the same time, BAC urges the Air Board to allow Book and Claim for biomethane used to produce low-CI electricity, provided both the biomethane and the electricity are produced and delivered consistent with the RPS and SB 1440.

1. Undelivered Biomethane Does Not Help California Reduce SLCP Emissions.

SB 1383 requires significant reductions in methane and black carbon emissions by 2030, and diversion of 75 percent of organic landfill waste by 2025. Biomethane generated in other states that is never delivered to California does not help to meet these critical climate and public health goals. This is why the Legislature, in SB 1440 (Hueso, 2018) requires that eligible biomethane must help achieve the goals of SB 1383.[1] SB 1440 further requires that the capture or production of eligible biomethane must directly result in at least one of the following environmental benefits to California: reduction of air pollutants or greenhouse gas emissions, reduction of water pollution, or reduction of odors in California.[2]

Only instate biomethane or biomethane that is actually delivered to California helps to meet the methane and black carbon reduction requirements of SB 1383 or to provide benefits to California's environment, as outlined in SB 1440.

The Air Board should phase out undelivered biomethane, as the 2023 staff proposals lay out, to help meet the requirements of SB 1383, reduce open burning and mitigate wildfire. Only instate or delivered biomethane provides these critical benefits.

2. Undelivered Biomethane Means that California Vehicles Will Continue to Use Fossil Gas.

From its inception, the Low Carbon Fuel Standard has had two goals, reducing carbon emissions and reducing fossil fuel use in motor vehicles. Continuing to allow credit for undelivered biomethane means that natural gas vehicles on the road in California will in fact be using fossil fuel gas. This is not a desirable result since fossil fuel production, refining and transport have adverse impacts on the environment and public health. It

[1] Public Utilities Code section 651(a)(1).

[2] Public Utilities Code section 651(a)(3)(B)(ii).

will also undermine support for the LCFS program since California drivers will continue to pay a premium for low carbon fuels that aren't even being delivered to California – in other words, Californians are being asked to buy something that they never in fact receive.

Phasing out the use of fossil fuels on the road in California requires that low carbon and renewable fuels actually be delivered and used to displace fossil fuels.

3. **Allowing Undelivered Biomethane Puts Instate Projects at a Severe Disadvantage.**

Allowing undelivered biomethane to participate in the LCFS reduces demand for instate biomethane, since instate production is significantly more expensive than out-of-state and undelivered fuels. California has stronger environmental, public health, labor, permitting, and other requirements. As an example, interconnection costs in California can be 2 to 10 times higher than in other states. California also has the most stringent pipeline biomethane standards in the country and the Air Board has recently proposed making pipeline biomethane standards even more stringent. Out of state biomethane projects do not have to meet California's standards to protect public health and pipeline integrity, which puts instate projects at a competitive disadvantage.

Continuing to make instate projects compete with undelivered biomethane will only slow the state's efforts to reduce SLCP emissions, landfilling, and wildfire as it makes it harder for instate projects to compete, both economically and in terms of the time needed to develop projects.

4. **The LCFS Should be Consistent with the Legislatively Mandated RPS and SB 1440 Programs.**

For all the reasons above, BAC urges the Air Board to go back to the staff proposals on the LCFS, which would have phased out undelivered biomethane consistent with the RPS and SB 1440. The 45-day language does not do this in any meaningful way. Projects built before 2030 will never be required to deliver their biomethane to California. And projects built after 2030 do not have to show delivery until 2040 or later and, even then, only have to inject the biomethane into a pipeline that flows in the general direction of California. This is not a clear standard and definitely does not ensure that the biomethane will help reduce SLCP emissions or provide other environmental benefits in California, as both SB 1440 and the RPS require.

5. **The LCFS Regulation Should Allow Book and Claim for Biomethane that is Delivered for Use in California, Including for Low-CI Electricity, Consistent with the RPS.**

BAC supports the use of Book and Claim for biomethane that is both generated and used in California or the western United States, whether it is used offsite as biomethane, for low-CI electricity generation or for hydrogen production. BAC urges the

Air Board to clarify in the amendments to the LCFS regulation that book and claim for biomethane converted to low-CI electricity is allowed, provided that both the biomethane and low-CI electricity production are consistent with the RPS. This could be done by adding conversion of biomethane to low-CI electricity in Sections 95488.8(i)(2) and 95488.8(g)(1)(A)(2).

246.2

B. CARB SHOULD NOT PHASE OUT CREDIT FOR AVOIDED METHANE EMISSIONS UNLESS THEY ARE REQUIRED BY LAW AND HIGHER EMITTING ALTERNATIVES ARE NOT ALLOWED.

BAC also urges the Air Board to continue to give credit for avoided methane emissions that are not required by law. This includes avoided methane emissions from livestock manure, which is not currently regulated, as well as avoided emissions from diverted organic waste projects where bioenergy can provide far greater carbon reductions than alternative products procured pursuant to CalRecycle's SB 1383 regulations. BAC appreciates that lifecycle analyses should not include emissions reductions that are required by law, but in both of these cases, the specific reductions are not required by law and should be credited in a lifecycle analysis.

1. Dairy and Other Livestock Waste

SB 1383 requires a 40 percent reduction in methane by 2030, but it does not include requirements for dairy methane reductions. On the contrary, the law requires a number of findings before the state can regulate dairy methane emissions[3] and those findings are difficult to impossible to achieve, so the State cannot currently regulate dairy methane emissions unless it changes the law. Therefore, dairy biogas producers should receive full credit for avoided methane emissions from dairy manure that is used to produce biofuels participating in the LCFS program.

2. Diverted Organic Waste

Diverted organic waste is a more complex category since SB 1383 does require 75 percent of organic landfill waste to be diverted from landfill by 2025. At the same time, neither SB 1383 nor CalRecycle's regulations require that diverted organic waste be converted to bioenergy. CalRecycle's SB 1383 regulations explicitly allow alternatives to bioenergy that emit far more carbon. Those alternatives include compost production and mulch, which are less expensive to produce than bioenergy, but also have greater carbon emissions.

CalRecycle affirmed this recently when it determined that a diverted organic waste to hydrogen project will have lower emissions than if that same waste were converted to compost (the finding required under Article 2 of CalRecycle's SB 1383 regulations). The State of Oregon's Department of Environmental Quality has also conducted a literature of 148 separate studies and found that bioenergy plus composting the

[3] Health and Safety Code section 39730.7(b)(4).

remainder (digestate) provide 3.5 times greater carbon reductions than compost alone.[4] More recent methane monitoring by NASA's Jet Propulsion Lab also found that compost production facilities emit substantial amounts of methane and yet this is an allowed alternative under CalRecycle's regulations.[5] None of this is to dismiss the value of compost, but where low carbon fuel can be generated instead, the difference in emissions should still be valued under the LCFS.

As long as CalRecycle's SB 1383 regulations allow higher emission alternatives to biofuels (biomethane, hydrogen or electricity generated from that waste), then the LCFS should continue to provide credit for the difference between bioenergy and other, higher emitting compliance products.

Thank you for your consideration of these comments.

Sincerely,

Julia A. Levin
Executive Director

Re: California Air Resources Board Proposal to Regulate Jet Fuel

Dear ARB Members:

I write on behalf of the Burbank-Glendale-Pasadena Airport Authority ("Authority") regarding the recent California Air Resources Board ("CARB") proposal to regulate jet fuel under its Low Carb Fuel Standard ("LCFS") program. As the owner and operator of Hollywood Burbank Airport ("BUR"), the Authority is supportive of feasible measures that fight climate change. The Authority is doing its part by striving for a LEEDS Gold certification for the Replacement Passenger Terminal project that is underway. Unfortunately, the LCFS proposal being considered by CARB will set a standard that is infeasible at this time.

The U.S. airline industry plays a vital role in California's economy. Furthermore, the industry is committed to reducing its climate impact and achieving "net zero" carbon emissions by 2050. Transitioning to Sustainable Aviation Fuels ("SAF") is core to this commitment, and the industry has pledged to work with governments and other stakeholders to make three billion gallons of SAF available in the United States by 2030. Achieving these goals requires new and additional policy incentives, streamlined permitting processes, and close collaboration among airlines, fuel companies, manufacturers, environmental organizations and governments, among others.

With respect to SAF, California has established itself as an early leader in attracting investment, production, and use of SAF through the existing LCFS Program, which provides an opt-in credit for SAF that helps reduce the price difference between SAF and conventional jet fuel. This voluntary regulatory structure has been successful in enabling the growth of the SAF market in California and across the country. California has the most viable market for SAF today in the United States and, as airlines increase their demand, the market continues to grow.

Aviation accounts for only 2.6% of United States' greenhouse gas emissions. In contrast, aviation's impact on the country's and the state's gross domestic product is significant, respectively amounting to 5% and 4.1%. There are 380,000 employees of United States commercial aviation firms based in California, with an overall economic impact of $194 billion[1]. Aviation is critical to driving California's economy and its rank as the 5th largest economy in the world. Aviation enables $114 billion in annual trade flows and underpins many of the rest of state's biggest economic drivers such as agriculture, tourism, manufacturing, banking, technology and small business. Ensuring a healthy and vibrant aviation industry is essential to California's future, and leveraging CARB's early leadership on SAF can enable California leadership in the emerging SAF production industry, creating new jobs and economic development opportunities.

[1] The Economic Impact of Civil Aviation on the U.S. Economy, State Supplement, US Department of Transportation, November 2020

2627 N. Hollywood Way • Burbank, California 91505 • (818) 840-8840 • Fax: (818) 848-1173

247.1 With this context, the Authority respectfully asks CARB to reconsider the proposal to regulate jet fuel as an obligated fuel under the LCFS Program. It our understanding that CARB's proposed changes to the LCFS Program include elimination of the existing exemption for conventional jet fuel use for flights within California. This proposed change is unlikely to result in increased SAF production, availability, or use in the state, but would lead to higher jet fuel prices. The International Air Transportation Association estimates that SAF production reached 158 million gallons in 2023, yet the U.S. Government Accountability Office estimates that 35 billion gallons of SAF will be needed by 2050 to satisfy 100% of demand. The primary impediment to increased SAF production and availability in California remains the higher cost of SAF for producers and buyers relative to conventional jet fuel and renewable diesel. CARB's proposal would not meaningfully address this fundamental challenge and therefore is unlikely to meaningfully increase SAF supply or use.

247.2 It bears emphasis that federal law preempts state agencies from regulating jet fuel to reduce emissions from aviation. CARB recognized this fact when it exempted jet fuel in 2018.[2] Aviation has unique circumstances, which go beyond considerations of interstate commerce, for the safe operation and maintenance of aircraft. Federal law, including the Clean Air Act, fully occupies this field and gives exclusive regulatory jurisdiction to federal agencies like the Environmental Protection Agency and the Federal Aviation Administration.

Moving forward with eliminating the fossil jet fuel exemption and implementation of a new obligation inevitably will result in lengthy and costly litigation that does nothing to advance the mission of increasing SAF production. Such litigation will divert resources from the state and the aviation industry that would be better spent enabling greater SAF production. Our mutual interest is to increase SAF production, availability, and use. The most effective way to accomplish this is to continue the positive, collaborative approach represented by the existing "opt-in" mechanism developed by CARB and the aviation community.

Based on these considerations, the Authority urges CARB to work with the aviation industry on another win-win solution. CARB should preserve the existing opt-in approach for SAF and partner with the aviation sector and stakeholders across the emerging SAF ecosystem on new policies and approaches to speed the availability of SAF in California.

Sincerely,

Frank R Miller

Frank Miller

California Air Resources Board
1001 I Street, 23rd Floor
Sacramento, CA 95814

Subject: Comments on Proposed Amendments Regarding Intrastate Jet Fuel Obligations and Less Intensive Verification

Dear Members of the California Air Resources Board,

Turner, Mason & Company (TM&C) appreciates the opportunity to provide comments on the 2024 proposed Low Carbon Fuel Standard (LCFS) amendments.

TM&C is an accredited verification body under the California LCFS, boasting a rich legacy of over 30 years working with petroleum and renewable fuel producers. With a team comprising seasoned consultants, each equipped with decades of first hand industry experience operating within Federal and State regulatory frameworks, TM&C stands as a trusted partner for clients navigating the intricate landscape of fuel compliance and verification. Through our extensive industry tenure and unwavering commitment to excellence, TM&C has consistently delivered invaluable insights to ensure regulatory compliance and operational efficiency for our clients.

I am writing on behalf of TM&C's verification body to provide comprehensive feedback on three critical aspects of the proposed amendments: 1) the inclusion of intrastate jet fuel as an obligated fuel, 2) the concept of less intensive verification, and 3) the current requirements for verification body rotation after six years.

Regarding the addition of intrastate jet fuel as an obligated fuel, we echo previous
248.1 concerns raised about the complexities and challenges associated with this proposal. The verification process for transactions involving this type of fuel would undoubtedly pose significant challenges, particularly given the intricate nature of traceability requirements.

It is crucial for CARB to engage not only with fuel producers but also with verification bodies to better understand the barriers and challenges inherent in the verification process. This collaborative effort will inform the development of effective verification methodologies and ensure that any regulatory measures implemented are grounded in feasibility and practicality.

Furthermore, CARB must ensure that there are clearly established methods for demonstrating and verifying the intended use of jet fuel for intrastate transport versus interstate or international transport. Without such clarity, reporting entities and verification bodies will face difficulties in meeting the requirements outlined in Section 95500(c) for fossil jet fuel used in intrastate flights.

Turning to the concept of less intensive verification, while we commend CARB for considering this approach to streamline the verification process, we believe there are opportunities for refinement to ensure effectiveness and equity. Specifically, we recommend extending the provision for less intensive verification services to encompass all transaction types listed in Section 95500(c)(1)(A through F), as well as the verification
248.2 of Crude Oil Quarterly and Annual Volumes Reports outlined in Section 95500(d). Additionally, eligibility for less intensive verification for Annual Fuel Pathway Reports (AFPR) should be extended to entities operating in manufacturing jurisdictions with established process safety regulations, as these jurisdictions demonstrate a higher level of internal control and compliance.

An assessment process for specific supporting information could be incorporated into the Notice of Verification to facilitate the application of less intensive verification. This would provide an opportunity for the Verification Body and CARB to determine whether there is sufficient supporting information to approve a less intensive verification process.

In addition to “less intensive verification”, CARB should consider eliminating the restriction of using the same verification body or individual verifier(s) to perform validation and
248.3 verification services for a period more than six consecutive years (see Section 95500(g)). This change would enable verification bodies to develop and maintain organizational competency and capability for the long-term thereby providing for increased sustainability of the LCFS validation / verification program.

With the experience gained from almost four years of validation / verification reporting, CARB should consider the performance history of the verification body or individual verifiers and not simply require a default change without a fundamental reason (i.e. cause). CARB has the authority to accredit and discredit verification bodies, lead verifiers, and verifiers based upon the competency requirements within section 95502(c).

In conclusion, TM&C believes that refining the proposed amendments to include these recommendations will enhance the effectiveness and fairness of the verification process while still achieving the intended goal of the program.

We appreciate the opportunity to provide feedback on this matter and look forward to the continued improvement of the regulatory framework.

Thank you for your consideration on these matters. If you have any questions, please reach out to us.

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Chair Liane Randolph,

On behalf of 1PointFive, I extend our gratitude for the opportunity to provide comments on the California Air Resources Board's (CARB) 2024 Proposed Amendments to the Low Carbon Fuel Standard (LCFS). 1PointFive is a Carbon Capture, Utilization and Sequestration company that is working to help curb global temperature rise to 1.5°C by 2050 through the deployment of decarbonization solutions, including Carbon Engineering's Direct Air Capture (DAC) and AIR TO FUELS™ solutions alongside geologic sequestration hubs.

We commend the state's unwavering commitment to climate action and leadership in incentivizing the deployment of carbon capture and sequestration (CCS) and DAC technologies. As a pioneer in sustainable practices, California has demonstrated the feasibility and efficacy of ambitious low carbon fuel standards, significantly influencing other jurisdictions in shaping their climate policies. California's leadership continues to catalyze a broader, collective commitment to fostering cleaner, more sustainable energy practices on a global scale.

California's dedication to reducing greenhouse gas (GHG) emissions sets a laudable example, and we appreciate the chance to contribute to the ongoing dialogue. Our comments are focused on the proposed amendments related to DAC and CCS. As identified by California's Scoping Plan, these technologies play a critical role in achieving the state's climate goals. We look forward to engaging in a constructive discussion to further enhance California's LCFS regulation.

Indirect Accounting of Low-CI Electricity in Direct Air Capture Projects

249.1 1PointFive strongly supports CARB's proposal to permit indirect accounting for low-CI electricity, biomethane and low-CI hydrogen.[1] Pursuant to CARB's proposed LCFS amendments, reporting entities may use indirect accounting mechanisms for low-CI electricity supplied as a transportation fuel, for hydrogen used as a transportation fuel, or *for direct air capture projects*, provided certain conditions are met. In conjunction with the amendment providing for indirect accounting for DAC, we also support CARB's proposed definition for "Book-and-Claim Accounting".[2]

1PointFive is currently constructing the first commercial scale DAC project which, once complete, will have a design capacity to capture 500,000 tons of CO_2 per year from the atmosphere. To maximize net removal of CO_2, DAC technologies require a continuous, reliable, and economic electricity supply. CARB's proposed amendments including indirect accounting methods for DAC, i.e., book-and-claim, are critical to ensuring the technical and commercial

[1] Proposed Amendments to the Low Carbon Fuel Standard Regulation, 17 CCR §95488.8(i)(1) ("Book-and-Claim Accounting for Low-CI Electricity Supplied as a Fuel, Direct Air Capture projects, or Used to Produce Hydrogen as a transportation fuel").
[2] Defined as "an indirect accounting system where a physical product and its environmental attributes can be separately traded...separated environmental attributes of low-CI electricity...may be matched under certain conditions to the use of grid electricity...." Proposed Amendments to the Low Carbon Fuel Standard Regulation, 17 CCR §95488.

feasibility of this nascent technology. And, as CARB noted in its Initial Statement of Reasons (ISOR), DAC is a key scoping plan component to meeting California's 2045 carbon neutrality goals.[3]

1PointFive's position is that book-and-claim accounting will also be a key contributor to the broader deployment of DAC at a climate-relevant scale. While small pilot-scale DAC projects may be able to rely upon "behind the meter" connections to provide needed energy, larger commercial-scale projects need multiple commercial-scale energy sources to ensure a continuous supply of energy. CARB's inclusion of book-and-claim accounting recognizes the challenges of optimally siting renewable and low-CI electricity projects, enables projects to enter into commercially competitive power purchase agreements with multiple energy sources, and serves as a powerful incentive for the development of new and expanded renewable and low-CI energy electricity generation.

Risk of Resource Shuffling and CARB's Proposed Criterion in 95488.8(i)(1)(C):

1PointFive is cognizant that any use of indirect or book-and-claim accounting must avoid creating or elevating the risk of "resource shuffling." To address this risk, CARB proposes that in order for reporting entities to use indirect accounting mechanisms for low-CI electricity supplied as a transportation fuel, for hydrogen used as a transportation fuel, or for direct air capture projects, five requirements or criterion must be met.[4] CARB explains that "[t]hese requirements will help ensure against resource shuffling where existing renewable electricity is potentially redirected to hydrogen production and backfilled with non-zero electricity."[5] Although not expressed in the ISOR, we understand that this reasoning applies equally to hydrogen and DAC.

1PointFive supports including amendments to the LCFS that will mitigate the risk of resource shuffling but recommends revisions to reflect the technical feasibility and commercial implications of imposing these criteria on DAC projects. **As part of its DAC development program, 1PointFive has carefully examined low-CI electricity sourcing and has determined that a book-and-claim accounting period shorter than 12 months is currently**
249.2 **infeasible and will severely constrain the deployment of this important climate mitigation technology.** Such a requirement should wait until such time when robust long-duration storage capacity is available, the necessary market and regulatory frameworks are in place, and sufficient dispatchable low-CI electricity is available, which we anticipate will not occur in this decade. Otherwise, the outcome of including this constraint would be harmful to the imperative to facilitate successive and rapid deployment of the initial generations of DAC technologies to progress along the technology learning curve and reduce costs to enable future deployment at a scale meaningful for climate mitigation.

CARB Should Require Low-CI Electricity to be Supplied to the Grid Within the Local Balancing Authority Where the DAC is Located

249.3 1PointFive supports CARB's recommendation that the low-CI electricity must be supplied to the grid within the local balancing authority where the DAC project is consuming the electricity. Furthermore, 1PointFive proposes that if the new low-CI electricity source from which the DAC

[3] California Air Resources Board, Staff Report: Initial Statement of Reasons. 32, 80, 124. Dec. 19, 2023; California Air Resources Board, 2022 Scoping Plan for Achieving Carbon Neutrality. 91-97. Nov. 16, 2022 ("increased deployment of DAC can help achieve net negative emissions…help[ing] avoid the most damaging impacts of climate change.").
[4] See, § 95488.8(i)(1)(C).
[5] California Air Resources Board, Staff Report: Initial Statement of Reasons. 34. Dec. 19, 2023.

249.4 project procures its electricity is not located in the same balancing authority as the DAC project, the DAC project must demonstrate that it can contractually and physically be able to supply the electricity to the grid within the local balancing authority where the DAC project is located. This will help mitigate the risk of resource shuffling or the double-counting of benefits.

CARB has already found that this approach, combined with the requirement that low-CI electricity be new or expanded (as required by criterion 3) did not lead to resource shuffling in the cap-and-trade program. The cap-and-trade program and the LCFS are two of the four credit trading programs California implements. Although the program frameworks differ in some respects, there are several similarities. Each establishes a declining target (for cap-and-trade, the total amount of permissible emissions, calculated on an annual basis, for LCFS, a carbon intensity applicable to transportation fuels that may be calculated on an annual or quarterly basis) and each allows for the creation and trading of credits (referred to as allowances under cap-and-trade) to meet annual compliance obligations.

The cap-and-trade program regulations expressly prohibit resource shuffling and in its analysis of the potential for resource shuffling within the cap-and-trade program, CARB found that California and Western Electricity Coordinating Council (WECC)-wide GHG emissions from electricity production decreased after 2013.[6] CARB analysis concludes that these decreases in emissions and the corresponding increases in zero-GHG and natural gas generation are key indicators the California Cap-and-Trade Program has not resulted in resource shuffling. Further, CARB found that declining costs of natural gas and renewable generation were driving year-over-year decreases in California electricity GHG emissions from both imports and in-State generation as in-State renewables more than doubled since 2013 and renewable generation in the WECC increased year over-year. We are confident that this analysis applies equally for the LCFS and should be used to inform CARB's consideration of the LCFS's approach to permitting annual balancing for DAC projects. We also encourage CARB to periodically update its review of the potential for resource shuffling for both the cap-and-trade and LCFS programs.

<u>CARB Should Focus on Ensuring that the Low-CI Power can be Accurately Tracked Rather than the First Contracting Entity</u>

1PointFive supports CARB's efforts to ensure that the low-CI electricity and associated environmental attributes are accurately tracked and accounted to mitigate the risk of double counting renewable energy certificate (RECs) or other environmental attributes. We understand that CARB's proposal that "The pathway holder must be the first contracted entity for procuring the low-CI power" is designed to mitigate this risk. However, 1PointFive recommends that rather than requiring DAC projects to be the first contracted entity, CARB should focus on requiring the pathway holder or project operator to prove that it can and has tracked the RECs and, in
249.5 accordance with CARB's proposed amendments, that credits are retired and not claimed under any other program, other than those expressly listed.[7]

In addition, CARB's proposed requirement is inconsistent with certain practical commercial approaches taken by companies to execute and manage power procurement contracts. In many cases, parent companies will establish an affiliate to manage their power purchase agreements, track, account and retire RECs and ensure electricity usage is managed on a daily basis across multiple decarbonization projects or business units. 1PointFive understands that CARB may be intending to prevent the double-counting of low-CI power procured and, if so, we recommend

[6] California Air Resources Board, Review of Potential for Resource Shuffling in the Electricity Sector. Feb. 2020.
[7] Proposed Amendments to the Low Carbon Fuel Standard Regulation, 17 CCR 95488.8(i)(5)(C)5.

that the criteria be changed to require the pathway holder (not necessarily the contracting entity)
249.5 to be the only entity that can claim the electricity and associated environmental attributes from the low-CI project, and such claim must be auditable and verifiable by CARB. In the alternative, CARB could revise this criterion to recognize commercial realities as follows:

> "The pathway holder, ~~or the~~ project operator or any of its affiliates must be the first contracted entity for procuring the low-CI electricity."

CARB Should Confirm that New or Expanded Low-CI Electricity Includes Repowered Sources

1PointFive fully supports the requirement that any low-CI electricity must be supplied by new or expanded low-CI electricity that begins new or expanded production on or after January 1, 2022, or within three years of the start of the DAC project. This is the key requirement to achieve CARB's goal to prevent resource shuffling. However, 1PointFive respectfully requests
249.6 that CARB confirms that a full repower of a renewable resource will qualify as a new low-CI source so long as it meets the criteria established by the Internal Revenue Service's "80/20" rule.[8]

CARB Should Permit Indirect Accounting on an Annual Basis

Requiring book and claim accounting to span a single quarter is neither technically feasible nor commercially viable. For direct air capture projects, we recommend that CARB revise its
249.7 proposed amendments to permit book and claim accounting for low-CI electricity on no less than an annual basis.

Allowing low-CI electricity matching to span a minimum of four quarters is necessary for a number of reasons. First, solar and wind energy capacity is subject to significant seasonal variability, regardless of the geographic location of the solar or wind energy generation. In the case of solar energy generation, seasonal variation is well documented across the United States and becomes more pronounced as latitudes increase. Consequently, any new and additional solar energy sources will provide significantly more electricity than a DAC project will need during summer months, particularly during the later days of a second calendar quarter and early days of a third calendar quarter but significantly less than a DAC project will need during the fourth and first calendar quarters. Seasonal variabilities in wind energy capacity are also well documented, although more dependent on geographic location. While seasonal variation in wind capacity is more localized, it is particularly pronounced on the west coast. Consequently, renewable power capacity, regardless of location, experiences significant seasonal variations, independent of and across multiple calendar quarters. Therefore, the use of book-and-claim accounting must be allowed to span at least four quarters to encompass a full seasonal cycle.

Some may suggest that renewable power generation combined with battery storage can address variabilities in the available renewable energy capacity. This is currently not a technically feasible or viable solution. Generally, large scale battery storage capacity is currently limited to less than four hours and suffers from pronounced energy degradation.[9] Battery storage can be configured for longer durations but not such durations sufficient to support a quarterly balancing period. Long duration energy storage (LDES) beyond 4 hours is a

[8] Definition of Energy Property and Rules Applicable to the Energy Credit, 88 Fed. Reg. 82188, 82211, 82218 (Nov. 22, 2023).
[9] Denholm, Paul, Wesley Cole, and Nate Blair. 2023. Moving Beyond 4-Hour Li-Ion Batteries: Challenges and Opportunities for Long(er)-Duration Energy Storage. Golden, CO: National Renewable Energy Laboratory. NREL/TP-6A40-85878. https://www.nrel.gov/docs/fy23osti/85878.pdf.

recognized challenge. The challenge is perhaps most clearly exemplified by the Department of Energy's (DOE) "Long Duration Storage Energy Earthshot" announced in 2022 that establishes a target to reduce the cost of grid-scale energy storage by 90% for systems that deliver 10+ hours of duration within the decade. In September 2023, the DOE's Office of Clean Energy Demonstrations announced funding of $325 million for nine proposals for LDES test projects. While these first projects (which have been selected but are yet to be awarded) appear promising, they also provide a clear indication that broader deployment of LDES, on both a technical and economic basis, is unlikely before 2035. DAC deployment cannot wait on these technologies to reach suitable duration, cost and deployment.

<u>Resource Shuffling is not Dependent on Whether the Use of Low-CI Electricity Spans Multiple Quarters</u>

We understand that CARB proposes a quarterly balancing period as a mitigating factor against resource shuffling. As CARB explains in its ISOR:

> "[L]ow CI electricity must be new or expanded capacity, must be delivered to the local balancing authority... and must be matched on a quarterly basis. These requirements will help ensure against resource shuffling where existing renewable electricity is potentially redirected... and backfilled with non-zero electricity."[10]

We agree that requiring new or expanded capacity low-CI electricity and delivery to the local balancing authority will help ensure against resource shuffling. However, as we discuss, *supra*,[11] we urge CARB to permit the use of low-CI electricity to span multiple quarters because we are confident that it will have no effect on, much less enable, resource shuffling. DAC projects seeking to maximize net CO_2 capture and sequestration will necessarily enter power purchase agreements with low-CI electricity suppliers. CARB's requirement that these sources be new or expanded will result in additional low-CI sources being developed and brought on-line to primarily provide energy to DAC projects, with excess energy provided to the grid. Delivery to the local balancing authority will help ensure that additional low-CI electricity projects will not permit high-CI energy to be sent to other balancing authorities. The additional criteria that RECs and other environmental attributes associated with the electricity are not issued credits or claimed produced or are retired and not claimed (except as permitted by the proposed amendment language) will require DAC projects to establish robust tracking, accounting and verification processes that meet or exceed CARB requirements. If these criteria are met, we are aware of no analysis suggesting that permitting the use of low-CI to span multiple quarters will somehow lead to resource shuffling.

<u>There is no Correlation Between Calendar Quarters and Renewable Electricity Generation</u>

The use of at least an annual balancing period should also be permitted because there is simply no correlation between calendar quarters and renewable electricity generation. In addition, to seasonal and year-over-year variations, renewable electricity generation varies significantly within quarters. This is not surprising because the calendar quarters in the United States do not align with seasonal electricity generation. The seasonal and year-over-year variability of renewable electricity generation is effectively illustrated by the California Energy Commission's (CEC) Visualization of Seasonal Variation in California Wind Generation website.[12] Users

[10] California Air Resources Board, Staff Report: Initial Statement of Reasons. 34. Dec. 19, 2023.
[11] CARB, Review of Potential for Resource Shuffling in the Electricity Sector.
[12] https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/visualization-seasonal-variation-0, last accessed February 17, 2024.

accessing the CEC's website can enter the month and year and generate a graphical representation of wind energy production The resultant graphs clearly show that wind energy generation varies significantly even within calendar quarters.

Global Deployment of Direct Air Capture is Critical for Achieving Cost Reductions and Climate Goals

California's leadership in addressing climate change is evident through its innovative approach to incentivizing DAC technology. By incorporating DAC into its LCFS regulation and allowing projects to be located anywhere in the world, California recognizes the shared nature of the atmosphere and the collective benefit of CO_2 emissions reduction and removal wherever it occurs on Earth. DAC technology has an important role in climate mitigation, but its widespread deployment is contingent upon achieving cost reductions through repeated deployment as rapidly as possible. California's precedent to allow for global deployment of DAC in its LCFS market helps facilitate accelerated deployment by enabling DAC projects to be located where they can be most effective and economical. Each DAC technology is most efficient in certain climatic conditions and requires access to low-CI power and secure geologic sequestration resources, which every jurisdiction cannot offer equally. DAC deployment at climate-relevant scale will therefore be greatly facilitated by market systems that enable deployment in the geographical regions they are best suited to.

As noted in its ISOR, CARB's LCFS program influences the development of similar programs in other jurisdictions, including Japan, the European Union, and Australia, with this list likely to grow in the future. Limiting DAC's geographic deployment to the United States, as proposed in § 95490(a)(2)(A), may encourage other jurisdictions to adopt similar deployment restrictions. Such restrictions will reduce the markets each DAC facility can access, making financing and deployment more difficult, and therefore hinder the ability to achieve rapid cost reductions to enable large-scale deployment. Global cooperation in emissions reductions and removals trading will be essential for optimizing the path to net-zero emissions. We encourage CARB to continue to allow for globally deployed DAC projects to generate LCFS credits.

Jointly Filed Application for CCS Credits

1Pointfive appreciates CARB's initiative to track the movement of CO_2 throughout the supply chain, from point of capture to secure storage. However, adding the entity responsible for transporting captured CO_2, as proposed by § 95490(c)(1), may obstruct development of CCS
249.8 projects because parties providing transport, are reluctant if not entirely opposed to taking on the responsibility of understanding subsurface geology and geophysics. Further, there is simply no reason for such parties to take on such tasks because carbon capture and sequestration projects may only generate LCFS credits once the CO_2 is stored in a CCS Project that has met the requirements of the CCS Protocol. In the unlikely event that captured CO_2 is lost by the party owning or operating the transportation infrastructure, those lost masses of CO_2 will never be included in a calculation of CO_2 for purposes of generating credits because the CO_2 never reaches the sequestration site. Accordingly, the responsibility for understanding subsurface geology and geophysics and the other requirements of the U.S. Environmental Protection Agency's Underground Injection Control Class VI regulation and the CCS Protocol are best imposed on the sequestration site owner/operator (even if there is a contractual allocation of risk, this is a matter between the parties in privity with the sequestration site operator).

However, we do recognize that where parties agree to submit a fuel pathway that maximizes LCFS credit generation through the use of a CARB approved sequestration project, it is appropriate that the fuel pathway be a joint application to ensure that the fuel pathway, which will receive the generated LCFS credits, can be held responsible for any credit invalidation.

Crediting Period for Carbon Capture and Sequestration Projects

California's Scoping Plan underscores the importance of point source carbon capture technologies, particularly in industries such as petroleum refining, cement production, and electricity generation from gas plants, to achieve its long-term climate target. 1PointFive
249.9 supports CARB's proposed amendment to allow the crediting period for CCS projects in the Refinery Investment Credit Program to extend beyond 2040 as proposed in § 95489(e)(5)(B). This proposal acknowledges the critical role of CCS in helping California achieve its ambitious climate goals and will enable ongoing investment and innovation in CCS technology, ensuring its long-term viability as a climate mitigation solution.

Conclusion

In closing, we fully support CARB's proposal to allow indirect accounting for low-CI electricity used by DAC projects. However, we believe there are significant challenges to requiring that low-CI electricity use by DAC span a single calendar quarter, including.

- Technological: As discussed, *supra*, pairing seasonal and intermittent low-carbon electricity generation (e.g., renewables) with long term energy storage technology is simply not achievable today at the scale needed to support DAC projects currently being deployed. Existing battery energy storage systems that have been deployed in the US generally have less than a 4 hours duration, and only represent a small portion of the available capacity of the grids where they are installed, making it infeasible to firm-up intermittent resources for sustainable periods. Furthermore, in order to maximize the amount of carbon sequestered, DAC technologies should not be cycled in response to the seasonality of renewable resources, and instead should operate at maximum capacity year-round. Annual matching, in conjunction with the additionality requirements, accomplishes CARB's goal of ensuring that enough new low-CI generation is installed in the grid where the project will operate, while allowing DACs to operate at full capacity year-round without the burden of having to over-build or over-procure.

- Logistics: The tracking, trading, and usage systems supporting energy attributes (e.g., RECs) currently only allow for annual time resolution; systems capable of handling shorter time resolution are projected to take years to put into place (with a few very limited exceptions like PJM and M-RETS). Moreover, the mere availability of tracking systems to handle shorter time resolution is not sufficient; robust liquid markets for shorter time resolution energy attributes will be needed to achieve acceptable supply and pricing risk for project finance. These markets will take years to develop. In the interim, there is no ability for a project to be able to cover this risk other than significantly over contracting/installing low-carbon intensity generation, putting undue financial stress on projects.

- Economics: The additional economic burden required to comply with the first two challenges is significant and risks stifling this nascent industry. We are concerned about the increased low-carbon power supplies required to cover for intermittent generation under a balancing period of one quarter. For example, we have estimated that on a quarterly reconciliation basis an additional 25% more power could be required to be over-contracted and not consumed by the DAC project, at substantial market price risk, compared with annual matching even in the most favorable locations for renewable resources.

Given the current technological, market systems, and economic landscape for continuous low-CI electricity supply, annual book-and-claim matching period is necessary and appropriate for DAC technology today. Annual matching, in conjunction with the additionality requirements, accomplishes CARB's goal of ensuring that enough new low-CI generation is installed in the grid where the project will operate to prevent resource shuffling, while allowing DAC projects to operate at full capacity year-round without the additional cost and risks associated with quarterly matching. Requiring additional low-CI energy production in the local balancing authority is the key to avoiding resource shuffling and not balancing periods shorter than 12 months.

We would like to express our sincere appreciation for the opportunity to offer our insights on CARB's proposed LCFS amendments. We value the dialogue surrounding these significant matters and look forward to further discussions. Should any inquiries arise, we are prepared to provide thorough responses. We look forward to continuing our collaboration and working together to deploy CCS and DAC technologies.

Sincerely,

Michael Avery

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

We appreciate the opportunity to comment on the Proposed Amendments to the Low Carbon Fuel Standard Regulation.

Based in Sunnyvale, CA, Antora is a thermal energy storage company that converts low-cost, intermittent renewable electricity into reliable, on-demand, zero-emissions industrial heat and power. Specifically, we are working to decarbonize industrial process heating for facilities that produce fuels for sale in California.

250.1 Antora strongly supports the use of clean energy in renewable fuel production, as detailed in the accounting framework for *Renewable or Low-CI Process Energy* in Section 95488.8(h) of the existing and proposed regulations. Section 95488.8(h) is designed to ensure the integrity of renewable and low-CI process energy used in fuel production, including by ensuring that renewable energy certificates (RECs) and other environmental attributes are not double-counted, as detailed in Section 95488.8(h)(1)(A).

Such a safeguard against double-counting of RECs and similar attributes is important to the integrity of the LCFS's decarbonization impact, as it ensures that any unit of renewable energy that is used to produce low-CI fuel sold in the LCFS market is not also claimed in another marketplace or program. However, the proposed amendments include a wording change (highlighted below) that could inadvertently provide *less* clarity to developers and potentially disqualify renewable energy inputs that align with the intent of the regulations:

> Any renewable energy certificates or other environmental attributes associated with the energy are not ~~produced,~~issued credits or ~~are retired and not~~ claimed under any other voluntary or mandatory program with the exception of the federal RFS [95488.8(h)(1)(A)]

250.1 This language inserts additional ambiguity for project developers due to the nuances of REC issuance, making it unclear whether certain issuance structures qualify. Under the proposed language of the provision, it remains unclear whether "are not issued credits or claimed" is equivalent to (i) "are neither issued credits nor claimed" or (ii) "either are not issued credits or are not claimed." That is, it is unclear whether both criteria must be met or either criteria alone is sufficient. In the former interpretation, a credit issued but not claimed (as described below)

ANTORA

1244 Reamwood Ave
Sunnyvale, CA 94089
www.antoraenergy.com

would be ineligible, despite no double-counting occuring—slowing the deployment of renewable fuel production and invalidating currently-eligible projects.

Under the structures of certain renewable energy and renewable fuel projects, a credit may be *issued* but not *claimed*, *used*, or *sold* except by the load associated with the renewable generation and claimed for the sole purpose of reducing emissions under the LCFS program. The issuance and separate use of the credit is useful in scenarios where separate, affiliated entities may be generating and consuming the electricity and the issue and sale of the REC is useful for accounting purposes between affiliates. In this scenario, the credit is not used to account for emissions reductions under other programs and thus would not represent double-counting when claimed under the LCFS. This scenario is likely to arise for renewable energy assets that provide some energy to low-CI fuel producers and some energy to the grid.

250.1 It is therefore critical that Section 95488.8(h)(1)(A) accounts for electricity where a credit is issued but not claimed under any other program. Reverting the language or making an amendment such as the following (bold and underlined) would maintain the integrity of the regulation without inadvertently restricting renewable energy production used and claimed solely for low-CI fuel production:

> Any renewable energy certificates or other environmental attributes associated with the energy **<u>either</u>** are not issued credits or **<u>are not</u>** claimed under any other voluntary or mandatory program with the exception of the federal RFS.

Thank you for the opportunity to comment. We look forward to working with CARB to further decarbonize the production of low-carbon fuels.

Sincerely,

Jordan Kearns

Re: Proposed Amendments to the Low Carbon Fuel Standard Expenditure Regulations

Dear Chair Randolph and Board Members:

As mission-aligned organizations focusing on economic and environmental justice in the clean energy transition, we appreciate the opportunity to provide comments on the proposed Low Carbon Fuel Standard amendments. Specifically, we would like to provide comments on the proposed changes to the expenditure regulations, related to the "allocation and uses of LCFS credits representing
251.1 non-metered residential EV charging". We applaud CARB's significantly increased focus on equity investments in the proposed revisions, and also want to share a specific concern and specific recommendations for some of the details, to ensure these changes have the desired impacts to meet our collective transportation electrification goals.

251.2 First and foremost, we want to express our strong support for the major LCFS expenditure changes being proposed by CARB, specifically:

251.2
- **Changing the scope of the statewide Clean Fuel Reward from a light-duty rebate to a medium and heavy-duty rebate.** A recent study in Nature Sustainability has quantified what our communities have known for decades - that pollution and health impacts from medium and heavy duty transportation are primarily and disproportionately borne by low-income communities and communities of color.[1] Catalyzing medium and heavy-duty electrification will begin to reduce
251.2 contd these harms, in addition to helping California meet its climate goals. The transition to zero-emission medium and heavy-duty transportation is essential to meeting air quality and climate standards; this transition is well behind the pace of the light-duty sector, so the proposed re-prioritizing of the CFR is appropriate.

251.3
- **Altering the minimum base credit contribution required to fund the Clean Fuel Reward from 60% of total base credits to 40% with a corresponding increase in holdback credits, and expanding the proportion of holdback credit proceeds required to be invested in disadvantaged, low-income, rural, and tribal communities.** Together these provisions

[1] https://www.nature.com/articles/s41893-023-01219-0 "*Air quality, health and equity implications of electrifying heavy-duty vehicles*"

251.3contd represent a significant increase in the overall percentage of LCFS credit proceeds invested towards transportation equity investments for low-income households. This smart strategy will both help CARB meet its equity goals and its transportation electrification goals, by focusing investments on the light duty market segments that are least able to transition to EVs without additional assistance. Both the light-duty equity and medium-heavy-duty investments take on even more importance due to the Governor's proposed cuts in budgetary support for ZEV incentives.

251.4

- **Adding workforce development programming to the pre-approved projects eligible for funding of holdback equity credits.** We specifically want to express our support for the addition of "re-skilling and workforce development for transportation electrification and electric vehicle infrastructure applications" as a pre-approved project category. However we are also concerned about a proposed elimination of a critical pre-approved project category, as 251.5 discussed below.

251.6 Secondly, we recommend rescinding and/or modifying some smaller proposed changes that propose to remove equity-focused outreach activities from the program regulations. Specifically:

- **CARB should retain and enhance the existing category of "Multilingual marketing, education, and outreach" within the list of pre-approved projects eligible for funding of holdback equity programs.** The Initial Statement of Reasons (ISOR) does not provide an explanation for why CARB is proposing to remove this category, and the proposed removal goes
251.6contd counter to the ISOR's stated goal of "***enhancing*** the pre-approved projects eligible for funding of holdback equity credits" (emphasis added).[2] Equity-focused community groups and stakeholders participating in CARB's Low Carbon Transportation Investments public work groups and convenings consistently are asking for ***greater*** investment in this area, and specifically investments that directly fund local community-based organizations who are trusted in priority communities and are best able to support Californians who have the most barriers to transitioning to EVs. We recommend that this category be retained in the revised regulations, and amended to explicitly pre-approve investments in outreach through funding provided to community-based organizations. ISOR doesn't explain why this is proposed to be removed, but if the concern relates to having electric utilities use holdback credit proceeds to fund their own internal work in this area, the language could be made specific to funding outreach via community based organizations that are based in and serve disadvantaged, low-income, rural, and tribal communities.

251.7

- **CARB should enhance the regulation's existing language regarding aligning holdback credit equity investments with the recommendations of CARB's SB 350 Low-Income Barriers Study.** CARB has been a leader in terms of operationalizing the recommendations of its SB 350 Low-Income Barriers Study[3], which represents the collective input and needs of a broad cross-section of equity stakeholders from EJ communities across the state around the barriers they see to adopting EVs and related technologies. These stakeholders invested

---

[2] ISOR, p. 36.
[3] https://ww2.arb.ca.gov/resources/documents/carb-barriers-report-final-guidance-document "*CARB Barriers Report: Final Guidance Document - Low-Income Barriers Study, Part B: Overcoming Barriers to Clean Transportation Access for Low-Income Residents*"

substantial time, resources and wisdom to help CARB understand how to best ensure that all of
our communities can access the benefits of EVs. We recommend that this language[4] be
amended to ***explicitly*** state that EDUs must align their portfolios of holdback credit equity
251.7contd projects with the findings and six priority recommendations[5] of CARB's SB 350 Low-Income
Barriers Study. CARB's proposed addition of workforce development as a pre-approved project 251.8
category aligns well with recommendation #5, and retaining and enhancing the pre-approved
251.9 outreach project category as recommended above aligns well with recommendations #2 and #3.

These smaller proposed changes, which mostly consist of retaining and refining existing regulatory
language, will provide critical support to ensure that CARB's proposed broader shift towards equity
investments is successful. As upper and middle income households increasingly have robust access to
affordable EVs in a maturing market, we are now faced with the much greater challenge of supporting
this transition for Californians with the lowest incomes and the most barriers to EV adoption. While
CARB's proposed increased financial investment in equity programs here will help, these barriers are
not just simply economic - they include cultural barriers, linguistic barriers, trust barriers, barriers related
251.10 to peer validation, and more. By authorizing investments in multilingual outreach programs through
trusted community-based organizations, and by ensuring that these broader investments are aligned
with the findings and recommendations of CARB's SB 350 Low-Income Barriers Study, CARB can help
ensure that we bring to bear the capacity and wisdom of our communities to ensure that every
Californian has the support they need to transition to zero-emission mobility.

Thank you for your consideration.

Re: BerQ RNG's Comments on Low Carbon Fuel Standard Initial Statement of Reasons

Dear Mr. Botill:

BERQ RNG ("BERQ") is a renewable natural gas company who develops, own and operates a portfolio of fourteen (14) projects in the US processing and upgrading biogas from dairy manure digesters, swine manure digesters and landfill gas into pipeline quality renewable natural gas ("RNG") representing an investment in this industry in excess of $450 million. BERQ currently has three (3) dairy digester projects participating in the CA LCFS by producing RNG dispensed as CNG in the California transportation market and has an additional eleven (11) projects in construction or late stage development undertaken in reliance on participation in the LCFS program.

BERQ appreciates the opportunity to submit comments to CARB on the proposed scoping plan Initial Statement of Reasons. ***We strongly support the proposed amendment allowing projects***
252.1 ***that break ground by December 31, 2029 to preserve the current approach of book and claim and the full three, 10 year avoided methane crediting periods to continue to incentivize the growth of the biogas to RNG industry as an integral component of achieving CARB's goals.***

We agree with CARB's goal of reducing methane emissions but believe the proposed rule lacks ambition to support this goal in the near term and thus ***we urge CARB to set more ambitious***
252.2 ***CI reduction targets of at least 25% in 2025 and at least 35% in 2030.*** Adopting these targets would greatly assist in reestablishing adequate demand for credits by depleting the credit bank and creating a more competitive market for the sale of credits.

CARB has proposed that all digester projects would be required to model one (1) lagoon cleanout a year in September even if this does not match the actual practice of the farm. Implementing this assumption would result in the Carbon Intensity scores of most biogas
252.3 digester projects becoming more positive by a range of 40-70 CI points causing a significant adverse impact on the economics of such biogas digester to RNG projects and may either cause planned projects to be cancelled or cause current or soon to be commercial biogas digester RNG projects to divert supply to alternative markets. While we understand CARB is proposing this change primarily to improve administrative simplicity of evaluating baseline conditions, we strongly urge CARB to reevaluate this position as modeling lagoon cleanouts

BerQ RNG
2400 Ansys Drive, Suite 102
Canonsburg, PA, 15317 USA
+1 (412) 656 8863

252.3 cont where they do not occur will lead to a gross underestimation of avoided methane emissions and cause investments in manure RNG projects to be greatly reduced.

Thank you in advance for your consideration.

Kind regards,

Martin L. Ryan

RE: Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Botill,

On behalf of the Canola Council of Canada (CCC) and Canadian Oilseed Processors Association (COPA) we welcome the opportunity to provide feedback on the *Proposed Low Carbon Fuel Standard Amendments (the proposed Amendments)*.

The CCC and COPA are non-profit industry associations that work collaboratively to help address issues impacting the value chain and oilseed processing sector in Canada.

California is among Canada's largest and most important customers for canola, with exports of oil and meal valued at $900 million in 2022. Canola oil has long been regarded as one of the healthiest cooking oils available and is also increasingly recognized as a low-carbon feedstock for renewable fuel production. Canola meal is also contributing to GHG emission reductions through its inclusion in dairy feed rations. Recent research shows that feeding dairy cows canola meal reduces enteric methane emissions while at the same time improving milk productivity[1].

Our industry is growing[2] and is committed to helping contribute to California's climate change objectives through increased utilization of low carbon fuels from sustainably produced canola. Since early 2021, more than $3 billion of processing capacity has been announced in Canada, equating to nearly 1 billion gallons of additional canola oil supplies for food and fuel markets. Owing to canola's natural ability to sequester carbon from the air and store this carbon in the soil via sustainable production practices such as reduced tillage, renewable fuels derived from canola are also recognized for significantly reducing GHG lifecycle emissions when compared to fossil diesel.

Given the growth of our sector and the proven GHG emission benefits of using canola as a low carbon and sustainable feedstock in renewable fuel production, changes to California's Low Carbon Fuel Standard (LCFS) are an important priority. We are pleased to provide the following feedback on *the proposed Amendments.*

---

[1] https://www.canolacouncil.org/news/new-research-demonstrates-increased-milk-production-and-reduced-greenhouse-gas-emissions-when-dairy-cows-are-fed-canola-meal/
[2] https://www.canolacouncil.org/about-canola/processing-industry/

1. **Treatment of Crop-Based Biofuels**

253.1 The canola industry in Canada appreciates CARB's analysis and recognition that its previous consideration of a cap or limitation on crop-based oil feedstocks is unwarranted and would increase fossil diesel use resulting in higher costs for consumers and greater GHG, PM2.5 and NOx emissions.

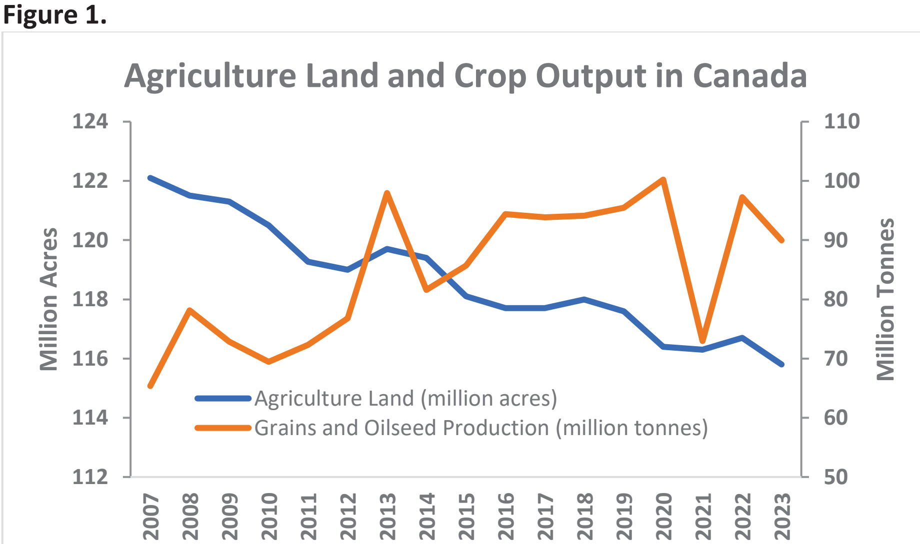
253.2 The proposed amendments that would subject crop-based feedstocks to sustainability certification and require tracking to their point of origin was not previously consulted by CARB. While we respect the importance of sustainability criteria in the development of low carbon fuel markets, it is important to work closely with stakeholders to understand its impact and develop practical solutions that limit unnecessary burden. Accordingly, we were encouraged to see a notice provided by CARB on February 14, 2024, informing stakeholders that staff plans to host a workshop in mid-April 2024 to discuss potential refinements to the proposed regulatory amendments, including the sustainability requirements.

253.3 To help inform this upcoming workshop and potential refinements to the sustainability requirements, our industry recommends CARB consider an option whereby feedstock can comply to sustainability requirements on aggregate in lieu of third-party certification. For example, provisions in the U.S. Renewable Fuel Standard (RFS) or Canadian Clean Fuel Regulation (CFR) provide options for jurisdictions to demonstrate that crop production does not contribute to negative land use changes or compromise biodiversity.

Due to advanced agricultural production practices, rigorous regulatory environments, and robust data sets validated by government, Canadian and U.S. crop-based feedstock already comply on aggregate with sustainability requirements in both the RFS and CFR respectively. A key metric to demonstrate compliance on aggregate is providing data/evidence that agricultural land is not expanding.

The Canadian government has been tracking agricultural land area for many years and official data shows land used for agricultural purposes has been in consistent decline (refer to Figure 1). While agricultural land area is shrinking, crop output continues to grow. This clearly indicates that crops grown and harvested in Canada do not contribute to deforestation or any associated adverse land use impacts. Furthermore, it is a testament to the innovation of crop production in Canada, with farmers deploying enhanced plant genetics and applying sustainable growing practices to grow more on less land.

Figure 1.



Source: Statistics Canada

253.3 contd An ‘aggregate’ approach to demonstrate compliance with sustainability requirements carries clear advantages for both CARB and market participants including:

1. It opens the door to a wider compliance option for CARB and allows for recognition of similar efforts taken in partner jurisdictions (i.e. U.S. and Canadian governments).

2. It encourages jurisdictions (not just individual entities) to demonstrate that their supply chains can and do meet sustainability criteria on key issues such as land clearance and deforestation.

3. Where sustainability equivalency can be demonstrated on aggregate across a jurisdiction, it will reduce the administrative burden and costs of feedstock supplies from those jurisdictions that are already fully meeting sustainability requirements under the rule.

Given the above advantages, we recommend the following regulatory text be added to section *(g) Sustainability Requirements for Crop-Based and Forestry-Based Feedstocks* in the *proposed Amendments*. This is not meant to prescriptive but instead offer a potential solution for CARB’s consideration.

> *“In lieu of subsection (g)(1), the Executive Officer may recognize legislation or regulation which has been enacted by a government authority in another jurisdiction where the effects of such legislation or regulation in that jurisdiction are assessed and deemed to be equivalent to the sustainability requirements under this rule”.*

253.4 We’d also like to take this opportunity to remind CARB that it has already accounted for land use impacts in the development of the LCFS through the incorporation of indirect land use change penalties (iLUC) – values which continue to be significantly overestimated. Accounting for iLUC and requiring sustainability guardrails to address concerns around land use impacts is unnecessarily duplicative in our view.

253.5 2. **Carbon Intensity Targets**

We continue to support the trajectory of increasingly stringent carbon intensity targets. Moving to a 30 % CI reduction from the baseline by 2030 is both appropriate and achievable. Increasing the stringency beyond 30 % is equally achievable, but to support these more aggressive targets, CARB should consider
253.6 the role of low carbon farming practices in the calculation of CIs for crop-based fuels. Incorporating carbon savings farm practices such as zero/min till or application of enhanced efficiency fertilizers are proven to significantly reduce emissions and contribute to lowering the CI of fuels in the marketplace.

253.7 We also applaud CARB for including a CI target for jet fuel in the amendments. Sustainable Aviation Fuel (SAF) is a growing opportunity to support the decarbonisation of air travel. Mandating a CI reduction for intrastate jet fuel is an important first step to encourage more production and consumption of SAF.

On behalf of the CCC and COPA, we appreciate this opportunity to comment, and look forward to an ongoing dialogue with CARB and other relevant stakeholders to enact changes to the LCFS that will address climate change while creating economic opportunities for those in the low carbon fuel value chain.

Sincerely,

Chris Davison
President and CEO
CCC

Chris Vervaet
Executive Director
COPA

Sacramento, CA 95814

RE: California Air Resources Board's Potential Changes to the Low Carbon Fuel Standard

Dear Chair Randolph,

Iwatani Corporation of America (ICA) would like to thank the California Air Resources Board (CARB) for the opportunity to comment on the potential changes to the Low Carbon Fuel Standard (LCFS) program. ICA owns and operates several hydrogen refueling stations across California and is rapidly expanding to serve the fast-growing hydrogen market in California and the U.S. ICA expects to have more than 15 light-duty stations in operation at the end of 2026[1]. Although the plans are not public yet, we are working on some very large heavy-duty projects that are expected to be shared in the near future. Since 1941, Iwatani has regarded hydrogen as the ultimate clean energy source and have consistently engaged in initiatives to encourage its widespread use. ICA is committed to support the zero emissions vehicle (ZEV) market by expanding the fueling infrastructure and supplying hydrogen to both light-duty and heavy-duty vehicles. Under the corporate slogan "A world where all enjoy true comfort – this is Iwatani's desire," we strive to solve environmental concerns with the aim of achieving a carbon free society through the use of hydrogen.

254.1 We want to congratulate CARB for developing and implementing the LCFS program which has saved more than 140 MMT of greenhouse gas (GHG) emission and surpassed expectations for renewable fuel growth production and reducing the carbon intensity (CI) of the transportation sector. Secondly, we support CARB in proposing potential changes to the LCFS program as we believe that the proposed changes make the program more efficient,
254.2 resilient, and can potentially accelerate investment into many projects contributing further to the decarbonization of the transportation sector. Please find ICA's comments on certain proposed changes to the LCFS program.

[1] This letter contains forward-looking statements that reflect management's views and assumptions in the light of information currently available with respect to certain future events, including expected financial position, operating results and business strategies. These statements can be identified by the use of terms such as "will," "believes," "should," "projects," "plans," "expects," and similar terms and expressions that identify future events or expectations. Actual results may differ materially from those projected, and the events and results of such forward-looking assumptions cannot be assured. Any forward-looking statements speak only as of the date of this letter, and no duty is assumed to update such statements. Factors that may cause actual results to differ materially from those predicted by such forward-looking statements include, but are not limited to: unanticipated changes in demand for the company's principal products, owing to changes in the economic conditions in the company's principal markets; changes in exchange rates or the impact of increased competition; unanticipated costs or delays encountered in achieving the company's objectives with respect to globalized product sourcing and new information technology tools; uncertainties as to the results of the company's research and development efforts and its ability to access and protect certain intellectual property rights; the impact of regulatory changes and accounting principles and practices; and the introduction, success and timing of business initiatives and strategies.

Increasing the CI reduction target pre-2030

254.3 As discussed during the workshops, the LCFS program has been successful in reducing and replacing fossil fuels, accelerating investment in low-carbon fuel production, ZEV infrastructure buildout, and facilitating the transition to 100% ZEV sales by 2035. According to the LCFS quarterly reports[2] published by CARB, not only has the volume and diversity of low-carbon fuels increased significantly within the past few years, but the CI of fuels has decreased leading to more LCFS credit generation and GHG savings. Moreover, substituting fossil fuels (gasoline and diesel) with low-carbon fuels and growth in ZEV sales have reduced the consumption of fossil fuels in the transportation sector. While this clearly shows that the LCFS program is overperforming, the demand for LCFS credits should be strengthened to balance the market and achieve the decarbonization goals. Nowadays, the LCFS credit bank balance is at a historic high and subsequently, the LCFS credit price, which is the main driver of investments in the clean fuels industry, is very low. To strengthen the demand for LCFS credits and restore the credit prices, CARB staff proposed increasing the stringency of CI reduction targets through 2030, however, ICA believes that the proposed CI reduction target (i.e., 30%) will not be enough to restore and stabilize the LCFS credit price and urges CARB to consider a greater CI reduction target, at least 40%, and implements the CI step down (5%) and auto acceleration mechanism (AAM) sooner than the proposed dates to restore the LCFS credit price faster and jumpstart the investment in production of clean fuels.

Infrastructure Crediting

254.4 Since CARB has established the infrastructure crediting program including HRI (hydrogen refueling infrastructure), and FCI (fast charging infrastructure) for light-duty vehicles, the number of fueling stations has grown significantly which is necessary for expansion of ZEV market and achieving ZEV mandate goals. The infrastructure crediting program has proven to be an efficient way to encourage ZEV infrastructure and support the state goals. ICA believes that a similar infrastructure crediting program for medium- and heavy-duty vehicles will help achieving the MHD ZEV Mandate targets. MHD ZEV is a necessary strategy for decarbonization of transportation sector and a more efficient way of using fuels (EER of 1.9 for MDH fuel cell). Hence ICA strongly supports CARB's proposal to extend the infrastructure crediting program to medium- and heavy-duty-(MHD) vehicles. Below are our comments regarding the current proposal:

- 254.5 ICA highly recommends considering 15 years instead of 10 years as the crediting period and extending the deadline for HRI application submission from December 31, 2030, to December 31, 2035. MHD ZEV infrastructure requires more capital investment compared to Ligh-Duty (LD) ZEV infrastructure and to make the investment economically feasible, the crediting period of MHD HRI should be at least equal to LD HRI which is 15 years. Additionally, extending the deadline for MHD HRI application submission is more aligned with the state's MHD ZEV mandate goals and creates more opportunity for MHD ZEV infrastructure development throughout California State.
- 254.6 ICA also believes that the 80% renewable content requirement can be costly and creates a burden for hydrogen refueling infrastructure and urges CARB to focus on CI and preserve the 40% renewable content requirement for the entire HRI crediting period.

Sincerely,

Hossein Tabatabaie

Director of Product Management

Sacramento, CA 95814

RE: Proposed Low Carbon Fuel Standard Amendments

Dear Dr. Cliff,

Montana Renewables, LLC ("MRL" or "the Company") appreciates the opportunity to comment on proposed amendments to the California Low Carbon Fuel Standard ("LCFS"). Since beginning commercial production little more than a year ago, MRL has established itself as a significant contributor of renewable diesel to California markets. Moreover, with sustainable aviation fuel ("SAF") production capacity amongst the largest in the nation, MRL is positioned to be a leading producer of this emerging and critically important low carbon fuel.

MRL is one of the true success stories of the LCFS program. Our parent corporation, Calumet Specialty Products Partners, L.P., ("Calumet") has operated a conventional oil refinery in Great Falls, Montana, for over a decade and in that time has provided high quality fuels and other products within its predominantly Montana/Upper Rockies service area. Thanks in large part to the incentives offered and demand created by the LCFS program and others like it, Calumet embarked on a bold plan to convert part of the Great Falls refinery to produce fuels from 100% renewable biomass, announcing the formation of MRL in November 2021. The result is a 15,000 bpd capacity renewable plant producing fuels from a wide range feedstocks (including animal fats, distiller's corn oil and canola) whose products are now sold by our offtakers in California, Oregon, Washington and British Columbia. The Company is not content to have merely joined the growing contingent of refiners that have announced plans to convert assets to produce renewable fuels; we have put our plans into action in near-record development time and have innovated along the way, including:

- steam methane reformer upgrades completed in March 2023 that have allowed MRL to become fully self-sufficient in its hydrogen needs;
- the installation of SAF assets in April 2023, allowing co-production of SAF with renewable diesel;
- the addition of on-site feedstock pretreatment capabilities in May 2023 using first-of-its-kind technology that should reduce energy consumption compared to traditional pretreatment processes; and,
- the first receipt of camelina oil in September 2023, which has great future promise to produce low carbon fuels from a sustainable feedstock that does not compete with traditional food crops.

We appreciate the efforts of the California Air Resources Board ("CARB") staff in engaging in a thorough stakeholder outreach program last year and recognize the significant commitment of time and resources that have gone into preparing the proposed amendments. The thrust of our comments today focus on expanding opportunities for SAF, as well as several other targeted regulatory measures to enhance incentives, increase transparency, and lower compliance burdens.

<u>Expanding Opportunities for Sustainable Aviation Fuel</u>

CARB's amendments propose to eliminate a long-standing exemption for conventional jet fuel, beginning in 2028, used for intrastate flights (meaning flights taking off and landing in California). We recognize that jurisdictional constraints may limit CARB's authority to impose new obligations on conventional fuels used in other flights. However, even within these limits, we respectfully believe that CARB could go further and faster to improve the incentive structure for SAF.

255.1

To start, we believe it is unnecessary to delay obligations for three years after the expected effective date of the amendments (January 1, 2025). For comparison, the original LCFS regulations – imposing entirely new and unfamiliar requirements throughout the fuel supply chain and for renewable fuel producers outside of California – were originally adopted in 2010 and obligations became effective January 1st of the following year. Against this backdrop, a three-year lead-in for jet fuel only if used in intrastate flights, within the context of a well-established program, seems unnecessary. We request that CARB reconsider whether a two- or even a one-year delay in implementation would better serve the state of California's overarching objective of reducing the carbon emissions from the aviation sector while still providing sufficient time for new and existing regulated parties to adjust to their obligations.

255.2

Besides the timing for implementation, we believe there are more targeted measures that CARB could take to support the rapid development and deployment of SAF. The proposed changes would, at best, only create indirect demand for SAF. Regulated parties for non-exempt conventional jet fuel would be under no compulsion to actually buy or blend SAF; they could simply purchase LCFS credits generated for wholly unrelated fuels to satisfy their newly created annual deficit obligations. Spurring investment and making a market for an emergent fuel requires policies with concrete obligations. The European Union and British Columbia have both recognized this in their respective renewable and low carbon fuel programs, each recently adopting a form of direct blending mandate for SAF. Consequently, we have over the last few months begun seeing a tremendous push from our offtakers and other market participants to ensure that SAF will be eligible in each jurisdiction. If California is to compete on even terms with these programs over the long term, CARB must keep the LCFS incentives structure on par. Even if CARB is unable to directly adopt a blending mandate within its current legal framework, it could achieve similar results by requiring regulated parties for conventional jet fuel to satisfy a percentage of their annual deficits via LCFS credits generated for SAF.

255.3

Beyond new incentives for blending SAF into the California aviation pool, CARB should review and align aspects of the LCFS regulatory framework to better allow producers to optimize the production of SAF (and therefore help defray its higher production cost on average compared to renewable diesel). To this end, we believe that CARB's final rule should address the allocation of commingled feedstocks to multiple product outputs from a production facility. The existing LCFS regulations begin to tackle this issue in Sections 95488.4(d) (setting forth the general rules for commingled feedstock allocation) and 95491(d)(1)(C) (providing an allocation formula to be applied each calendar quarter). These rules are a reasonable accommodation to the reality that fuel producers rarely can segregate and batch-run individual feedstocks. The rules and CARB's related interpretive guidance (see LCFS Guidance 19-08) further allow producers to optimize the feedstock-to-fuel allocations for shipments to California, as long as a quarterly material balance is maintained. However, neither the existing rules nor guidance directly address situations like MRL's and many other renewable distillate producers, where more than one fuel product is produced in a quarter.

Two types of feedstock allocation methodologies addressing multiple product outputs have emerged under other programs. The “proportional allocation” methodology requires allocation of each feedstock used in the same proportions as products produced in a given quarter; Table 1 below provides an illustrative example for a generic producer of renewable diesel (RD), SAF and renewable naphtha (RN)[1]:

Table 1: Proportional Allocation Methodology Example

Feedstock Type	Feedstock Qty (gal)	RD Volume (80% Yield)	SAF Volume (15% Yield)	RN Volume (5% Yield)
Soy	35,000	28,000	5,250	1,750
Canola	40,000	32,000	6,000	2,000
Tallow	25,000	20,000	3,750	1,250

255.3 contd

In the above scenario, the producer would be limited to allocating only 3,750 gallons out of 25,000 gallons worth of tallow – the best performing feedstock from a carbon intensity perspective – to SAF production. Compare this outcome with a “free allocation” methodology, which still requires a producer to fully account for all feedstocks used in a quarter but gives the producer greater flexibility to assign those feedstocks to product output, as depicted in Table 2 below:

Table 2: Free Allocation Methodology Example

Feedstock Type	Feedstock Qty (gal)	RD Volume (80% Yield)	SAF Volume (15% Yield)	RN Volume (5% Yield)
Soy	35,000	35,000	0	
Canola	40,000	35,000	0	5,000
Tallow	25,000	10,000	**15,000**	0

The benefits to the producer under free allocation should be obvious. But so, too, should the benefits to California if the state truly wishes to incentivize more SAF production and consumption. By allowing the allocation of the lowest-carbon feedstocks to SAF, producers will be better able to cover the higher average cost of production and would be better incentivized to expand SAF production capacity. Neither allocation methodology would alter a producer’s overall feedstock mix nor impact calculation of CI in the GREET model; the methodologies are simply about how to assign feedstocks from the mix to different product outputs. Feedstock usage still would remain subject to annual verification to ensure quarterly material balances are maintained. And in many ways, adopting a free allocation methodology would harmonize California’s approach with other jurisdictions and programs (such as the ISCC CORSIA and PLUS protocols and the emerging Canadian Clean Fuels Regulation) that in meaningful ways are competitors for nascent SAF supply. We urge CARB to take the opportunity afforded by this amendment process to build on the existing LCFS regulatory framework and adopt the free allocation methodology described above for producers of multiple transportation fuels.

[1] For the sake of simplicity, the examples in Tables 1 and 2 above assume 100% conversion of feedstocks to the three listed products. In reality, a small percentage of feedstock yield loss and/or use in producing other co-products (such as renewable LPGs) would be expected and must be accounted for by producers.

Comments on Other Proposed Changes and LCFS Policy

We address below several other issues raised by or otherwise germane to CARB's proposed LCFS amendments.

Credit True Up After Annual Verification

255.4 MRL strongly supports the proposed amendment to 17 CCR 95488.10(b), which would authorize the Executive Officer to perform a credit true-up for a fuel pathway that has a lower verified operational CI, as evidenced in its annual fuel pathway report, than the CI for which the fuel pathway was previously approved. We believe this amendment properly rewards producers that invest in emission reduction improvements or are otherwise able to "overcomply" with their registered pathways. In addition, the proposed amendment should encourage producers to conservatively calculate and assign margins of safety to their CI scores during the pathway registration process, since the benefits of overcomplying would be returned to the producer in the credit true-up rather than being lost to the LCFS buffer account (as is the case in the current regulations). We request that CARB make the credit true up provisions effective immediately, meaning that the first opportunity for such true up would occur after the submission of Annual Fuel Pathway reports in March 2025 (for calendar year 2023/2024 data).

Deficit Calculation for Verified CI Exceedance

255.5 CARB has proposed amendments to 17 CCR 95486.1(g) that would subject non-provisional pathway holders to a calculated obligation of four times the number of deficits in the event of a verified CI exceedance. MRL agrees with the importance of maintaining compliance with fuel pathways; however, we believe that the proposed amendment as written could be unnecessarily punitive. There are reasonable, no-fault circumstances that may trigger a CI exceedance in a given fuel pathway reporting year (e.g., an unexpected asset or facility outage; feedstock supply disruptions leading to sourcing from more distant locations; undetected meter reading errors; etc.). We recognize that the proposed credit true-up language described above should incentivize conservative calculations and margins of safety, but the possibility of CI exceedance still exists even with these safeguards. If the "four times penalty" is included in the final amendments, we request that CARB adopt an additional condition that the penalty would not apply if, in the year following the exceedance, the fuel pathway holder is able to both fully comply with its registered CI *and* make up the difference in the exceedance based on the reported CI score in its annual fuel pathway report. This approach would be very similar to the "deficit carryover" concept that exists under the current U.S. Renewable Fuel Standard program, wherein an obligated party would not be penalized for falling short of its renewable volume obligations in year 1 as long as such shortfall and all other obligations are met in year 2. We believe this would be a reasonable compromise to help avoid triggering a punishment for what may be an atypical (and in many cases unpreventable) CI exceedance in a given year.

Sustainability Requirements for Crop-Based Feedstocks

255.6 CARB has proposed amendments at 17 CCR 95488.9(g) that would impose new sustainability obligations for crop-based feedstocks. MRL is supportive of sustainable production. We ask that CARB provide specific examples of existing third party certification systems, if any, that would satisfy the prescribed criteria proposed in Section 95488.9(g)(1)(B).

255.7 We also believe that CARB should engage in a collaborative process with all stakeholders in the development and approval of consensus-based sustainability certification systems, and should tie the effective date of these new requirements to the adoption of these consensus standards.

255.8 To facilitate a smooth transition to the new sustainability obligations, we urge CARB to consider nation-level exemptions or to at least temporarily delay the effective date of these requirements for crop-based feedstocks originating in the U.S. and Canada. Such nation-level exemptions are common concepts that have been embraced under the U.S. Renewable Fuel Standard and Canadian Clean Fuels Regulation. U.S. and Canadian crops do not raise the same degree of sustainability concerns that undoubtedly have motivated the proposed new requirements. For these reasons, we believe nation-level exemption or implementation delays for U.S. and Canadian crops would be a reasonable addition to the sustainability amendments if finalized.

Changes to Annual Standards, Near-Term Step Down, and Automatic Acceleration Mechanism

CARB has proposed a variety of changes aimed at increasing the stringency of the program and, correspondingly, the demand for LCFS credits. These changes are a reflection of the overwhelming success of the program in incentivizing low carbon fuel production and consumption in California to-date. We note, however, that the proposed 5% reduction in the CI benchmarks in 2025 (referred to as the "near-term step down") could have unintended consequences for existing renewable fuel producers. Each of the aforementioned measures attempt to head off a growing credit surplus that could stifle prices and deter

255.9 future investments. If credit prices do not rise at the speed or to the degree CARB forecasts in its rulemaking analysis, the near-term step down could end up doing more harm than good for existing producers; credit generation would be curtailed by the sharp decline in the 2025 benchmark without a corresponding rise in prices to help offset these losses. We ask CARB to carefully consider the credit availability and pricing analyses of other stakeholders in their comments in evaluating the necessity of the near-term step down versus a more gradual approach to achieving the proposed 30% CI reduction target by 2030. CARB should also consider whether de-coupling the proposed CI benchmarks for diesel substitutes and fossil jet fuel substitutes, allowing the latter to progress at a slower pace, would more

255.10 appropriately reflect the current state of the industry and afford greater credit generation potential (and incentivizes) for SAF produced from existing feedstocks and production technologies.

Streamlining Verification Requirements

MRL is currently or expects to soon be subject to annual verification or audit obligations under LCFS or LCFS-like programs in the states/provinces of California, Oregon, Washington, British Columbia, and

255.11 Alberta, as well as the U.S. Renewable Fuel Standard, the Canadian Clean Fuels Regulation and the ISCC. We recognize and support the need for independent review to facilitate regulatory oversight and market confidence in the validity of emission reductions represented by credits. We ask CARB simply to consider where there may be opportunities to reduce redundancies and streamline verification obligations for consistency with equivalent programs, and to remain open to alignment on these requirements in the future.

* * *

Thank you for considering these comments. We look forward to working collaboratively with CARB throughout this rulemaking process. Please do not hesitate to contact us with any questions.

Regards,

Greg Staiti

February 20, 2024

VIA ELECTRONIC FILING

The Honorable Liane M. Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Preliminary Staff Report Proposed Low Carbon Fuel Standard ("LCFS") Amendments

Dear Chair Randolph and California Air Resources Board's Transportation Fuels Branch Staff,

On behalf of the undersigned companies, we are pleased to provide comments on potential changes to California's Low Carbon Fuel Standard ("LCFS") program. We appreciate the opportunity to engage with Air Resources Board ("ARB") staff during this process.

Under ARB's leadership, California's LCFS program has been an important driver of the State's greenhouse gas emissions ("GHG") emissions reductions. It has not only provided a model for similar programs in other states, but also proved just how successful such programs can be. As of the most recent data, from Q3 2023[1], California has reduced transportation emissions by over 15% below 2010 levels, an achievement consistent with the program's current 2026 target. That is extraordinary progress!

However, ARB's LCFS amendments proposed in the Initial Statement of Reasons (ISOR), released on December 19th, 2023[2], jeopardize the program's progress in the years to come.
256.1 ARB's proposed amendments to the program's carbon intensity ("CI") targets fail to bring the
program's ambitions in line with its performance, thus presenting broad challenges to every producer of low-carbon fuels and risking a sharp drop in clean fuels and technologies investment.

Additionally, the ISOR's sharp adjustment of the treatment of LCFS base credit generation for residential charging of light-duty electric vehicles ("LD EVs") is extremely problematic. Accelerating LD EV adoption is crucial for the state to achieve its GHG emissions reduction
256.2 goal; but at a time when LD EV adoption may be slowing, ARB has proposed to terminate the
California Clean Fuel Rewards ("CCFR") program for LD EVs. As is, the proposal would effectively eliminate LD EV automakers ("OEMs") from the program, because under the proposal there would be no economically viable way for OEMs to participate.

256.3 We believe the most effective changes ARB could make to its proposal are to adjust the
magnitude of the Step-Down to set the program's CI targets ahead of its performance in the
256.4 256.5 short-term; to adjust the timing of the Auto Acceleration Mechanism; and to revive and rework

[1] https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries
[2] https://ww2.arb.ca.gov/rulemaking/2024/lcfs2024?utm_medium=email&utm_source=govdelivery

256.5 cont. the CCFR for LD EV purchases. If ARB does not revive the CCFR, it should at least allocate a significant portion of base credits for residential EV charging to OEMs, which play the lead role
256.6 in enabling and accelerating EV adoption and are best positioned to support ARB's objectives.

I. Carbon Intensity Targets

We commend ARB for proposing to implement a 5% carbon intensity ("CI") reduction target Step-Down, to 18.75% in 2025. ARB has also proposed to increase the 2030 CI reduction target to 30% from its current 20%.

As noted above, both ARB and the market are well aware of the program's current success: as of Q3 2023, the achieved CI reduction of transportation fuels in California was ~ 15.5% below 2010 levels, 4.25% more than the 2023 target of 11.25%.[3] At this rate it is quite likely that by the end of 2024 the achieved CI could be 18.75%.

Given that, finalizing both a near-term Step Down and a higher 2030 target are both sensible and defensible actions. However, the timing and magnitude of ARB's proposals in the ISOR are insufficiently ambitious.

256.7 Since the ISOR's release, LCFS prices have dropped over 20% to levels not seen since 2015.[4] The market is sending a clear signal to ARB that it believes performance is likely to continue outpacing targets - including the updated targets in the ISOR - and that the LCFS program could be a victim of its own success.

We believe the fundamental issue with the Step-Down as proposed is that it is too little to fulfill its fundamental purpose: to reset the ambitions of the program ahead of its performance.

This is particularly true since ARB has proposed adjusting the 2010 baseline CI for ultra-low sulfur diesel ("ULSD") upwards by 5.3%, from 100.45 gCO2/MJ to 105.76 gCO2/MJ. This adjustment effectively negates any impact of the Step-Down on ULSD, since the new "stepped-down" 2025 target of 85.93 gCO2/MJ is less than 1% below the current target[5]. The impact of this is to increase the supply of credits from renewable diesel, which already generates the most credits in the program.

Climate research suggests that it's imperative to reduce emissions sooner rather than later. ARB can build on the program's extraordinary progress by setting more ambitious targets between now and 2030, such as those proposed by the Low Carbon Fuels Coalition.

---

[3] BTR estimate.
[4] OPIS Carbon Market Report, January 24, 2024
[5] Proposed Low Carbon Fuel Standard Amendments, Appendix A-1, Proposed Regulation Order, Table 2, Footnote (a), pg. 66.

Recommendations:

256.8
- Adjust the magnitude of the Step-Down from the proposed 5% below the current 2025 level to at least 10%.
    - This implies a new 2025 CI reduction target of at least 23.75% below the 2010 baseline.

256.9
- Set a 2030 CI reduction target greater than 30%.

II. Automatic Acceleration Mechanism

While an appropriate Step-Down and 2030 target are the most effective means to build on the program's success and provide an incentive for continued investment in response to the visible near-term oversupply of credits, the Automatic Acceleration Mechanism ("AAM") is an important tool to allow the program to adjust for unforeseen imbalances more flexibly in the future.

256.10 ARB proposes to delay the first trigger of the AAM until 2027, which would not impact CI reduction targets until 2028 - three years after ARB's proposed Step-Down in 2025.

We believe that timing is too late and encourage ARB to consider an earlier, modified trigger, in line with that proposed by the Low Carbon Fuels Coalition.

Recommendations:

256.11
- Allow the AAM to trigger in 2026, one year after the effective date of the Step-Down in 2025.

256.12
- Adjust the bank-to-deficit ratio to 2.5 from 3.0.

III. Residential LD EV Charging Credits

Background

Since ARB's last amendments in 2018, the LCFS program has provided crediting pathways for residential LD EV charging credits to both electric utilities and OEMs. The utilities are awarded "base" credits in a volume proportional to the reduction in emissions from an internal combustion engine vehicle fueled by gasoline relative to a "non-metered" LD EV charged with grid-average electricity. OEMs can generate "incremental" credits by purchasing low-CI electricity, typically through purchase of a Renewable Energy Certificate ("REC"), to pair with "metered" EV charging, evidenced using data from vehicle telematics.

There are five important factors to bear in mind about base and incremental credits under the current program:

1. Utilities receive base credits for no cost but must agree to spend the associated credit revenue for specific purposes, as directed by ARB.

2. OEMs may generate incremental credits but must agree to spend the associated credit revenue for specific purposes and must also bear the REC cost and any associated costs of collecting vehicle telematics data including, as ARB has proposed, third-party verification.
3. The current magnitude of the incremental credit relative to the base credit, in terms of transportation emissions reductions per MWh, is approximately 2.7 times lower.
4. The magnitude of the incremental credit value relative to the base credit value, in terms of dollars per MWh, is over 19 times lower, based on current 2024 LCFS and REC prices estimates, as shown in Table 1 below.
5. Beginning in 2023, CARB has relied on “metered” vehicle telematics data provided by the OEMs for incremental credit generation as the “best available data” to establish the volume of “non-metered” base credits awarded to utilities.

Table 1: Base and Incremental Credit Generation Revenue Comparison[6]

Utility Base Credit Value Calculation	***EV OEM Incremental Credit Value Calculation***
Base Credits/MWh EV Charging: 0.775	Incremental Credits/MWh EV Charging: 0.29
2024 LCFS Price: $64.18/MT	2024 LCFS Price: $64.18/MT
Gross Revenue/MWh: $49.74	Gross Revenue/MWh: $18.61
2024 REC Cost: N/A	2024 REC Cost: $16.00
Net Revenue/MWh: $49.74	Net Revenue/MWh: $2.61

While the existing crediting pathways provide most of the volume and value of the emissions reductions generated by LD EV adoption to the utilities, OEMs nevertheless have been incentivized to participate in and generally support the LCFS program for two primary reasons.

First, until recently, there had been a sufficient LCFS price incentive coupled with a sufficient amount of eligible low-CI electricity to generate positive economics for incremental credit generation.

Second, and most importantly, ARB required utilities to spend 60% of LCFS base credit revenue to fund on-the-hood incentives for LD EV purchases through the CCFR.

256.13 ARB’s proposals in the ISOR upset and diminish those incentives by transforming the CCFR from a light-duty to a medium- and heavy-duty (“MH EV”) incentive program and introducing third-party verification requirements and costs on the OEMs that cannot be covered by the now marginal value of incremental credits.

[6] ICE End of Day Market Report, LFS-California Low Carbon Fuel Standard Credit ($/MT) Future, 2/16/24; BTR estimates.

Transformation of the California Clean Fuel Rewards Program

ARB proposes to transform the CCFR program from a universal new LD EV rebate to a rebate focused available for new and used MH EVs that are exempted from the Advanced Clean Fleets regulation.

ARB's rationale for its proposal to redirect the program away from LD EVs and towards MH EVs is to "jumpstart the transition for a harder to transition segment of the truck sector that is not otherwise covered by other CARB regulations."[7]

However, we believe that removing incentives funded by base credits for LD EV adoption is both short-sighted and problematic for three reasons.

256.14 First, multiple studies show that purchase incentives remain critical to ensure the transition of EV ownership from only early adopters to a wider group of buyers. Incentives under the Inflation Reduction Act (IRA) are not available for many LD EV models, which makes programs like the CCFR that much more important to support continued adoption. Unlike other programs, the CCFR is not dependent on a California state budget allocation, and, before it was paused, it was one of the last remaining financial incentives in California for LD EVs.

Second, LD EV adoption is critical to the success of the LCFS program and to achieving California's GHG emissions reductions goals generally. We forecast that electricity credits will account for 50% of total credits by 2030 and 65% by 2035, with LD EVs accounting for between 75-80% of that volume if LD EV adoption continues to grow.[8]

Third, LD EV adoption continuing to grow and ultimately reaching California's ambitious targets is not a foregone conclusion. Recent market indicators paint a troubling picture of LD EV adoption. Inventories of LD EVs hit a record high in December 2023, reaching two times the level of the prior year.[9] Annual sales growth for LD EVs this year has been forecast to be only a quarter of 2023's level.[10] LD EVs remain more costly than comparable internal combustion engine (ICE) models, and a high interest rate environment increases the cost of financing the purchase.[11]

Despite the importance of LD EV adoption, ARB proposes to remove direct consumer adoption incentives at a moment when there is little to no value from residential incremental crediting, no alternate crediting pathway or base credit value available for OEMs, no value available from the federal Renewable Fuel Standard for electricity used as a transportation fuel, and an uneven availability of federal incentives for LD EV adoption.

[8] BTR estimates.
[9] Bloomberg Hyperdrive, "America's EV Rethink," January 4th, 2024.
[10] Ibid.
[11] Ibid.

Third-Party Verification Requirements

ARB also proposes to introduce third-party verification requirements on incremental credit generators. This is problematic for four reasons.

256.15

- In its Standardized Regulatory Impact Assessment (SRIA), ARB assumed a $6/MWh verification cost.[12] Even assuming a cost one-third that level, third-party verification costs significantly diminish the economic incentive for OEMs to generate incremental credits under the current LCFS and REC price environment, as shown in Table 1(a) below.
- These additional costs are imposed on OEMs for reporting the "best available" vehicle telematics data that establishes the volume of base credits awarded to the utilities.
- ARB's proposal specifically exempts the utilities from any third-party verification requirements for base credits.
- In its current form, third-party verification requires site visits which may conflict with requirements imposed on incremental credit generators by the 2018 California Consumer Privacy Act, particularly for residential EV charging, not to mention be unfeasible given the hundreds of thousands of vehicles reporting.

Table 1(a): Base and Incremental Credit Generation Revenue Comparison

Utility Base Credit Value Calculation	***EV OEM Incremental Credit Value Calculation***
Base Credits/MWh EV Charging: 0.775	Incremental Credits/MWh EV Charging: 0.29
2024 LCFS Price: $64.18/MT	2024 LCFS Price: $64.18/MT
Gross Revenue/MWh: $49.74	Gross Revenue/MWh: $18.61
2024 REC Cost: N/A	2024 REC Cost: $16.00
Net Revenue/MWh: $49.74	Net Revenue/MWh: $2.61
Third Party Verification Cost: N/A	Third Party Verification Cost: [$2.00]
Net Revenue/MWh: $49.21	Net Revenue/MWh: $0.61

ARB's own quarterly data shows that over the past four reporting quarters, residential incremental credit volume has dropped 75%, from 15% of overall residential credits to just under 4%.[13] Additional verification costs as proposed by ARB will significantly diminish the economic
256.16 viability of incremental credit generation and, in turn, the incentive for OEMs to provide vehicle telematics data.

---

[12] Standardized Regulatory Impact Assessment, 9/8/2023, Appendix A: Methodology for Estimating Costs, pg. A-1

[13] https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries; BTR estimates.

256.16 cont. This would have the perverse result of forcing ARB to once again estimate non-metered utility base credit volumes at the exact time that ARB is specifically phasing out estimation in other electricity crediting pathways.

Recommendations:

256.17 OEMs play a core role in enabling and accelerating the transition to LD EVs. OEMs enjoy comparatively strong relationships with consumers and act as primary distributors of information regarding the consumer and environmental benefits of LD EVs. OEMs also guide consumer preferences by providing compelling LD EV products (e.g., rate plans and managed charging programs) to help maximize the emissions reductions and grid incentives associated with LD EV adoption.

Without the CCFR or some other form of programmatic support for LD EVs, the two market participants <u>most directly responsible</u> for light-duty vehicle electrification and resulting emissions reductions – the OEMs who produce and sell the LD EVs and the drivers who purchase and use them – could be eliminated from the value chain of LCFS entirely, a departure from the first principles of the LCFS program.

256.18 As such, we believe ARB should revive and rework the LD EV CCFR. If ARB does not maintain the LD EV CCFR, it should establish a structure that provides OEMs a durable share of base credit generation for residential EV charging, creating a more inclusive program in which the roles of different stakeholders are more appropriately balanced and ensuring programmatic targets are met.

256.19

- ARB should maintain the existing LD EV rebate from the CCFR but make OEMs and a third-party administrator – rather than the utilities – responsible for administering it.
    - Over the past three years under its existing administration, the CCFR incentive was first halved and then indefinitely paused, creating confusion for customers.
    - OEMs have decades of experience administering vehicle rebates and are better positioned than utilities to administer an LD EV CCFR, since they are customer-facing at the important "point-of-decision" and could better communicate directly with customers.
    - To provide a stable and predictable incentive, ARB and OEMs should set the CCFR LD EV purchase reward annually based on estimated revenue from LCFS credit generation from residential LD EV charging.

256.20

- If ARB instead is determined to finalize its proposed MH EV-focused CCFR program, then ARB should award to the OEMs a portion of the base credits which are not dedicated to the new CCFR fund. OEMs could use the base credit revenue to fund specific projects that benefit EV customers, as directed by ARB, as well as administrative costs related to those projects and to the collection of LD EV vehicle telematics data and the costs of ARB's proposed third-party verification requirements.

256.20 cont. OEMs are by far best positioned to support certain projects already identified by ARB in the ISOR to be valid uses of base credit revenue. For example, ARB has identified various vehicle-grid integration projects such as encouraging the optimization of LD EV charging, providing incentives for managed charging and demand response, supporting the installation and deployment of bidirectional charging capabilities, and developing innovative approaches that benefit both drivers and the grid.[14] All of these projects require significant investment and could be better facilitated by OEMs. Awarding a portion of base credits to fund these investments would provide three key advantages for ARB and the LCFS program.

- First, it would accelerate the managed charging, vehicle-to-home (V2H), and vehicle-to-grid (V2G) technologies that OEMs are already developing.
- Second, it would underpin an incentive that OEMs could offer drivers at purchase, on an ongoing operational basis, or both.
- Third, if implemented in parallel to the changes in the Smart Charging Lookup Table Pathway detailed in Section IV below, it would reinforce the incentive for OEMs to encourage drivers to optimize their charging to hours with the lowest grid emissions and to provide information on utility rate pricing, etc. at the point of sale.

256.21
- If ARB does not award to OEMs a portion of the based credits, we would encourage ARB to consider revising § 95500(c)(1)(E)(1) to state, "EV Charging except as specified under 95491(d)(3)(A) *and 95491(d)(3)(B)*" (new text in italic). This would exempt both metered and non-metered residential charging from third-party verification.

IV. Adjustments to the Smart Charging Lookup Table Pathway

256.22 As noted above, because incremental credit generation requires the purchase of RECs to pair with the LD EV telematics data, the associated LCFS credit revenue must be sufficient to cover REC costs plus the cost of aggregating, filtering, and reporting the telematics data and any cost of capital associated with the REC costs.

One targeted yet limited change ARB can make that would provide a floor for incremental credit generation economics would be to remove the current requirement in the Smart Charging Lookup Table Pathway that reporting entities must demonstrate that "the FSE was enrolled in a Time-of-Use rate plan during the reporting period."[15] This would enable participation in the

---

[14] Proposed Low Carbon Fuel Standard Amendments, Appendix A-1, Proposed Regulation Order, §95483(c)(1)(A)(5)(b)(ii)(I-IV), specifically "Support for vehicle-grid integration with projects such as: I. Encouraging the optimization of EV charging through education in the following areas: peak demand, rate pricing, grid emergencies, potential power shutoffs, infrastructure deferral, renewable integration, and/or other signals and grid needs to provide grid and customer benefits. II. Providing program incentives to encourage driver participation in monitored/managed charging, demand response, or vehicle-to-load / vehicle-to- grid applications. III. Supporting the deployment and installation of bidirectional charging equipment. IV. Other innovative approaches to promoting and managing EV charging and discharging that provide benefits to customers and the grid.

[15] Proposed Low Carbon Fuel Standard Amendments, Appendix A-1, Proposed Regulation Order, § 95483(c)(1)(B)(1)(b)

Smart Charging Lookup Table Pathway when other incremental credit pathways are not economically viable.

256.22 cont.

This change would require only two minor adjustments to existing regulatory language and would have little impact on any existing credit generation since few if any fuel reporting entities have ever utilized the Smart Charging Lookup Table Pathway for either metered residential or non-residential charging.

Recommendations:

We encourage ARB to revise § 95483 and § 95491 as follows:

- § 95483(c)(1)(B)(1)(b): Smart charging. ~~In the case of an entity claiming smart charging incremental credits, the credit generator must demonstrate the residence is enrolled in a Time-of-Use rate plan, if offered by the LSE serving the residence.~~
- § 95491(d)(3)(B)(3)(d): ~~Records must be provided to the Executive Officer, upon request, demonstrating the FSE was enrolled in a Time-of-Use rate plan during the reporting period, if offered by the LSE.~~
- We further recommend that CARB update the Application and Reporting Instructions for the Smart Charging Lookup Table Pathway to reflect these changes.

V. Adjustments to the Requirements for Low-CI Electricity

256.23

The supply of RECs eligible for demonstrating low-carbon intensity (low-CI) electricity generation for incremental book-and-claim crediting under the LCFS program is limited relative to other state clean fuel standard programs in the WECC due to ARB's deliverability restrictions on low-CI electricity.

This supply limitation jeopardizes the economic viability of incremental credit generation, particularly at a moment when LCFS prices are historically low and there is no alternate crediting pathway or base credit value available for OEMs.

Recommendations:

- Amend the deliverability requirement such that low-CI electricity from generating units registered in WREGIS and located in *any* state in the WECC may be used for incremental crediting, even if such low-CI electricity is not scheduled into a California balancing authority.
- Exercise ARB's authority as a "Program Administrator" under the WREGIS Operating Rules to introduce flexibility specifically for LCFS-eligible RECs into the generating unit registration requirements imposed by WREGIS.

256.24

V. Other Programmatic Changes and Clarifications

Geofencing Radius for Residential EV Charging

256.25 ARB should consider reducing the current "conservative" Geofencing Radius (GFR) of 220 meters to a smaller and more precise GFR, as described in LCFS Guidance 19-03, Appendix A "Rationale for Minimum and Maximum Geofencing Radius." The GFR is used to "disaggregate the quantity of electricity used for residential and non-residential EV charging" and should be as precise as possible.

We are concerned that as charging station network operators and utility companies install more charging stations, an increasing amount of residential EV charging will be erroneously categorized as non-residential and therefore ineligible to generate credits. This will be particularly acute in densely populated urban areas of a mixed-use commercial/residential nature.

We believe that geolocation data (latitude, longitude) provided by non-residential reporting entities, as well as the precision of on-vehicle telematic systems, supports a higher precision GFR. We note that the Washington State Department of Ecology proposed a "conservative estimate of 110 meters or less for the maximum GFR to geofence a residential charging location."[16]

Hierarchy of Incremental Credit Generation for Residential EV Charging and Non-Metered Incremental Credit Generation

256.26 OEMs are currently second in a "hierarchy" of stakeholders eligible to generate incremental LCFS credits for residential EV charging. This hierarchy provides little value to the efficacy of the LCFS and unnecessarily complicates the registration process. OEMs generate the vast majority of all incremental LCFS credits generated for residential LD EV charging; furthermore, the "best available data" from their metered vehicle telematics establishes the volume of non-metered residential base credits.

We recommend ARB consider either eliminating the hierarchy and establishing OEMs as the sole stakeholder eligible to generate incremental LCFS credits for residential LD EV charging or reorganizing the hierarchy such that OEMs are the first- priority credit generator.

256.27 ARB should also clarify in the regulation that OEMs may designate a third-party to act as a first-priority credit generator on their behalf.

256.28 Finally, ARB should also allow OEMs that report metered vehicle telematics data to generate incremental credits for non-metered residential charging. Using the same metered vehicle

[16] https://apps.ecology.wa.gov/publications/SummaryPages/2314029.html

256.28 cont. telematics data and vehicle registration data, ARB could establish the volume of non-metered residential charging for which OEMs may generate incremental credits by purchasing a REC.

VI. Conclusion

256.29 We encourage ARB to continue to pursue aggressive policies that support California's climate goals. As the transportation sector is the largest sector contributing to greenhouse gas emissions, reducing those emissions is critical to achieving carbon neutrality. The LCFS has been an important and effective tool, but it will only continue to perform if ARB makes changes like those described above.

We thank you again for the opportunity to provide these comments, and we look forward to continued engagement with ARB staff. If we can provide additional information or further support your efforts, please contact any of the undersigned.

Sincerely,

RE: Sonoma Clean Power Authority Comments on Low Carbon Fuel Standard Proposed Amendments

Dear Chair Randolph and Executive Officer Cliff,

Sonoma Clean Power Authority ("SCP") offers the following comments on the Proposed Amendments to the Low Carbon Fuel Standard ("LCFS"). SCP's comments focus on Amendments that will affect electric vehicle charging. SCP is a community choice energy provider and is committed serving EV charging load with low-CI power. SCP's comments are summarized as follows:

1. SCP Supports the proposal to classify Multi-family Residences as non-
residential EV Charging for purposes of LCFS credit generation. This
257.1 proposal will provide much-needed revenue to facilitate EV charging in
this important customer segment and should be further expanded to
apply to all multi-family residences, not just those with shared parking.

2. CARB should amend the Regulation to provide that all 100% RPS or
zero-CI electricity tariffs are be able to generate LCFS credits without
257.2 proving that Renewable Energy Credits ("RECs") were not retired for
the RPS.

257.3 3. CARB should clarify that amendments to the REC language in Section
95488.8(i) would not preclude the use of RECs to generate LCFS
credits.

DISCUSSION

1. Community Choice Aggregators ("CCAs"), like SCP, Are Committed to Providing Carbon Free Energy to Supply EV Charging in Their Territories, Including Multi-Family Residences.

SCP is the community choice energy provider for Sonoma and Mendocino counties, apart from Ukiah and Healdsburg which have existing municipal utilities in their service territories. SCP's service territory includes a population of about a half-million, with our energy demand split roughly in half between residential and non-residential customers. In downtown Santa Rosa, SCP operates the only Advanced Energy Center[1] in the United States dedicated to helping customers transition to 100% renewable energy for their homes, businesses, and cars. SCP is also the only power provider in California offering 100% renewable energy generated within our service territory twenty-four hours per day, every day of the year.

In addition to developing renewable and low-GHG resources, SCP offers an evolving suite of programs to help educate customers and unlock the benefits of a clean energy economy. Some of these programs include:

- Free residential electric vehicle chargers: SCP provides customers with an up-front discount of 50% on the cost of a Level 2 EV charger and an additional $250 incentive if the customer activates and enrolls their charger in SCP's demand response program, GridSavvy Rewards.[2] Since 2016, this program has supported the installation of 4,908 additional Electric Vehicle Supply Equipment ("EVSEs") in our territory. In addition, through our participation in the California Electric Vehicle Infrastructure Project ("CALeVIP"),[3] we have built another 103 publicly-available, Level 2 chargers, and 10 DC fast chargers. In 2024, SCP will consider revisions to the program to reach more low-income customers and underserved communities.

- Non-profit electric vehicle incentives: SCP offers reimbursement to non-profits to help them transition from gas-powered vehicles to clean EVs. SCP offers a $15,000 incentive for EV passenger vehicles and a $22,500 incentive for vehicles with payloads over 1,500 pounds (e.g., vans and trucks). To date, this program has supported the purchase of 19 electric vehicles by local non-profit organizations.

---

[1] Advanced Energy Center: https://scpadvancedenergycenter.org/.

[2] GridSavvy Rewards program: https://sonomacleanpower.org/programs/gridsavvyrewards.

[3] CALeVIP provides funding for installing publicly available EV charging stations to support the rapid adoption of electric vehicles across California: https://calevip.org/about-calevip.

- Drive EV: From 2016 to 2019, SCP's Drive EV Program enabled 1,258 customers to purchase electric vehicles at a collective discount of over $14 million. By providing financial incentives and exchanging free marketing for participating EV dealers in exchange for dealer and manufacturer discounts, the program reduced the average EV sales price by over $10,000 (from $38,523 to $27,759) *in addition* to any state or federal incentives.

- Bike Electric: Launched in 2021, SCP has supported its Bike Electric[4] program to incentivize electric bike ("E-bike") ridership by offering income-qualified customers a $1,000 incentive toward the purchase of an E-bike to promote their use instead of car ridership for short trips. Since its inception, the program has provided incentives for 423 E-bike purchases. One of the lessons learned from our Bike Electric program is that many of the E-bikes purchased were being used for recreation (78% of respondents) or exercise (65%). Only 22% said they used their new E-bikes for commuting. SCP has set a goal to improve on those metrics by targeting local employers and providing grants for organizations that want to make electric bike commuting more accessible to their employees.

These programs have been designed to encourage EV usage throughout our diverse customer base. In particular, we have developed a suite of EV strategies that provide benefits to customers, but we have been limited in our ability reach customers that don't own their residence. Multi-family residences represent a unique challenge because the residents are typically renters and do not make decisions about whether the residence will have EV charging capability. The Proposed Amendments would help facilitate access to EV charging in these situations by amending Section 95843(c). The Proposed Amendments would clarify that multi-family residences will be considered non-residential EV charging to the extent that charging equipment is not limited to serving dedicated or reserved parking spaces. SCP supports this clarification in the LCFS and if adopted by CARB, SCP will evaluate how it can use these incentives to continue to grow EV penetration in the SCP service territory. To better effectuate access by multi-family residents, this amendment should be expanded to include all multi-family residential charging and not limited to EVSEs installed in shared parking spaces.

2. **CARB Should Broaden the Application of Green Tariff Programs and Clarify that that 100% RPS or Zero-CI electricity Tariffs are Eligible Even if Renewable Energy Credits ("RECs") Are Not Retired.**

Currently, the LCFS Regulation only allows a certain class of Green Tariff Shared Renewables Programs to be eligible for low-CI charging. The Regulation states that Green Tariff Shared Renewables include programs are described in Public Utilities Code Section 2831-2833. For all other sources of energy supplied to EV charging, the fuel provider must demonstrate that it retired RECs associated with the power and that the RECs were not used for the RPS or other programs. The narrow class of GTSR programs included in the aforementioned

[4] Bike Electric Rider's Guide: https://sonomacleanpower.org/bike-electric.

PUC code unfairly limits other voluntary renewable programs that may be similar in nature, but have not been expressly authorized by the CPUC. This limitation is arbitrary because it effectively precludes non-EDUs from qualifying for the GTSR provisions for no other reason than the fact that the entity is not an EDU subject to CPUC jurisdiction.

Since the adoption of the last amendments to the LCFS Regulation, there has been considerable growth of CCAs and 100% RPS or Zero-CI electricity retail offerings. RECs are used under these programs for RPS compliance, but that does not change the fact that the low-CI energy is still additional to low-CI energy, the offering has a CI that is lower than the grid-average, and often includes low-CI energy in excess of what is already required by the RPS. Forcing CCAs participating in the LCFS to choose whether to use their RECs for RPS or low-CI energy places an unfair burden on CCAs that does not further the fundamental objectives of the LCFS (i.e., achieving the maximum technologically feasible and cost-effective emission reductions). Moreover, this requirement is unnecessary in light of the fact that retail offerings by load serving entities are now subject to extensive, GHG-based reporting under the California Energy Commission's Power Source Disclosure program. Limiting GTSR programs to those governed by the CPUC unnecessarily restricts feasible emission reductions and arbitrarily discriminates against non-EDU LSEs. To address this issue, SCP recommends amending Section 95488.8(i) to remove the reference to Sections 2831-2833 of the Public Utilities Code.

3. CARB Should Clarify that Amendments to the REC Language in Section 95488.8(i) Would Not Preclude RPS Eligible Projects that Generate RECs.

The Proposed Amendments include changes to REC requirements in Section 95488.8(i)(1)(B)(3). The Proposed Amendments would remove the current language stating that RECs cannot be retired under any other program. The Proposed Amendments would provide that electricity cannot be "issued credits." Currently, entities claiming incremental EV charging rely on power generated by facilities that generate RECs for the entirety of the electricity delivered to the grid. Under existing LCFS rules, the Fuel Supplying Entity will use RECs and prove that the RECs were not used for the RPS by retiring the RECs to a WREGIS retirement account that is used solely for LCFS compliance. RECs can only be retired once and by retiring RECs to an LCFS-specific retirement account, this action proves that the RECs were not also used for the RPS.

Under the Proposed Amendments, electricity from a project that is "issued credits" would not be eligible. The introduction of the word "or" in this Section suggests that either generating RECs or retiring them in another program precludes RECs from being used in the LCFS. This reading would effectively preclude any RPS-eligible power plant from being used to supply incremental energy. RPS eligible resources generate RECs for all generation delivered to the grid. It is then up to the LSE to decide how to use the RECs (e.g., use them for the RPS or the LCFS). Limiting the generation of RECs in the first instance would preclude LSEs from participating in incremental EV charging. We do not believe this is CARB's intent, and would recommend retaining the existing language in Section 95488.8(i).

CONCLUSION

SCP appreciates the opportunity to submit written comments on the proposed amendments to the LCFS Program. We look forward to continuing to work with CARB to incentivize EV charging and low-CI power in SCP's territory and throughout the state.

Respectfully submitted,

Neal M. Reardon

Subject	Comments for LCFS amendments CARB from SGH2 Energy Global Corporati

Comment

Currently, SGH2 Energy is in the process of developing and
building
a green hydrogen plant from biomass/waste non-recyclable paper.
1. The facility will be requiring power to run the plant. We
need about 6 -8 MW of power for the plant operation, which is
standard processing equipment like pumps, compressors, sensors,
258.1 and
electronics. And this power is not used for electrolytic H2
production. We request that we use book and claim of renewable
energy credits to cover for this power consumption. For
comparison,
an electrolytic hydrogen production plant to produce similar
hydrogen as our plant (4,000,000 Kg), would require a 100 MW of
solar panels.
2. Methane - global warming potential (GWP) should be calcula
based on 20 years. Methane being a potent greenhouse gas which
traps heat in the atmosphere and contributes to climate change.
Over a 20-year period, methane's GWP is between 84 and 87, meaning
258.2 that one ton of methane emitted today has the same GWP as 84 to 87
tons of carbon dioxide over the next 20 years. And methane also
has
a short half-life, and its impact is only in the first 20 years.
Therefore, there is no reason to calculate its GWP over 100 years
3. According to EPA, landfill gas when captured is not more t
50%. Not all California Landfills are capped for gas. Therefore,
258.3 we
recommend CARB use EPA statistic and only 50% of landfill gas can
be captured.

Board Comments Home

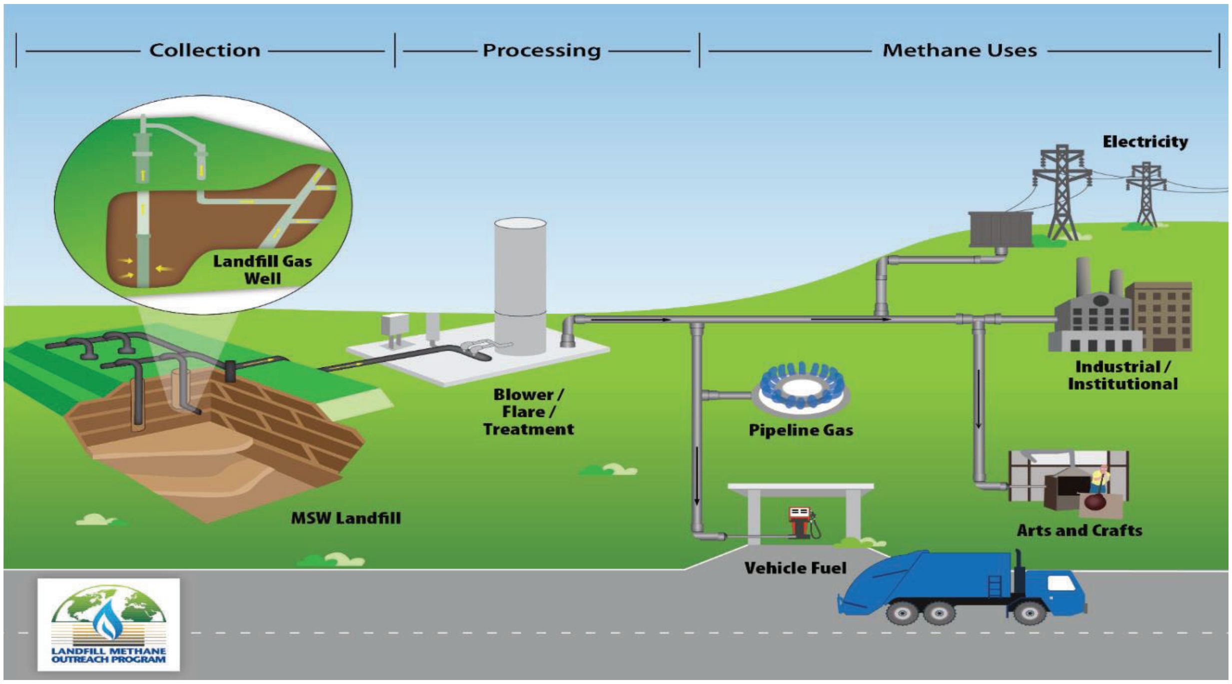
Landfill Gas Methane Capture Information

Landfill gas (LFG) is a natural byproduct of the decomposition of organic material in landfills. LFG is composed of roughly 50 percent methane (the primary component of natural gas), 50 percent carbon dioxide (CO_2) and a small amount of non-methane organic compounds. Methane is at least 28 times more effective than CO_2 at trapping heat in the atmosphere over a 100-year period. Landfills are the third largest source of anthropogenic methane in the United States. According to the EPA, landfill gas (LFG) comprises 17.7 percent of all U.S. methane emissions

Instead of escaping into the air, LFG can be captured, converted, and used as a renewable energy resource. Using LFG helps to reduce odors and other hazards associated with LFG emissions, and prevents methane from migrating into the atmosphere and contributing to local smog and global climate change.

LFG is extracted from landfills using a series of wells and a blower/flare (or vacuum) system. This system directs the collected gas to a central point where it can be processed and treated depending upon the ultimate use for the gas. From this point, the gas can be flared or beneficially used in an LFG energy project.
LFG collection efficiency capture can achieve 85 percent efficiency or more in closed and engineered landfills; it is least effective in open dumps, where the collection efficiency is approximately 10 percent and capture is typically not seen as economically favorable.

Available options to convert LFG into energy include categories such as – Electricity Generation, Direct Use of Medium-Btu Gas, and Renewable Natural Gas.



The cost of an LFG project depends on a number of factors, including the size, location, and layout of the landfill. Typically, one million tons of landfill waste emit approximately 432,000 cubic feet of LFG per day, enough to produce either 0.78 MW of electricity or 216 MMBtu of heat.

Approximately 70 percent of LFG projects generate electricity, primarily via internal combustion engines, gas turbines, and microturbines. Costs vary, but internal combustion engines (ICEs) smaller than 1 MW typically cost $2,300/kW to install, with annual operation and maintenance costs of $210/kW, and ICEs larger than 800 kW typically cost $1,700/kW, with annual operation and maintenance costs of $180/kW. Revenue depends on electricity buy-back rates that are specific to local electric utilities, but typically range between 2.5 and 7 cents/kWh.

<u>Example of current usage of LFG capture for energy:</u>

BMW Manufacturing Landfill Gas Energy Project:

Location:	Greer, South Carolina
End User(s):	BMW Manufacturing Co.
Sector(s):	Auto manufacturing

Landfill(s):	Palmetto Landfill
Landfill Size:	22.9 million tons waste-in-place (2015) [closed]
Project Type:	Combined Heat and Power (cogeneration – two gas turbines)
Project Size:	6.5 megawatts (MW) generation [11 MW rated capacity]
Savings:	$1 million/year
LMOP Partners Involved:	Ameresco, BMW Manufacturing Co., Durr Systems, South Carolina Energy Office, Waste Management

At its South Carolina assembly plant, BMW began using landfill gas (LFG) from Waste Management's Palmetto Landfill in 2003 to fuel four gas turbine cogeneration units (4.8 MW rated capacity) and recover 72 MMBtu per hour of hot water. The turbines fulfilled about 25 percent of the plant's electrical needs and nearly all of its thermal needs.

Methane emissions: choosing the right climate metric and time horizon

Paul Balcombe,*[ab] Jamie F. Speirs,[bc] Nigel P. Brandon[bc] and Adam D. Hawkes[ab]

Methane is a more potent greenhouse gas (GHG) than CO_2, but it has a shorter atmospheric lifespan, thus its relative climate impact reduces significantly over time. Different GHGs are often conflated into a single metric to compare technologies and supply chains, such as the global warming potential (GWP). However, the use of GWP is criticised, regarding: (1) the need to select a timeframe; (2) its physical basis on radiative forcing; and (3) the fact that it measures the average forcing of a pulse over time rather than a sustained emission at a specific end-point in time. Many alternative metrics have been proposed which tackle different aspects of these limitations and this paper assesses them by their key attributes and limitations, with respect to methane emissions. A case study application of various metrics is produced and recommendations are made for the use of climate metrics for different categories of applications. Across metrics, CO_2 equivalences for methane range from 4–199 $gCO_{2eq.}/gCH_4$, although most estimates fall between 20 and 80 $gCO_{2eq.}/gCH_4$. Therefore the selection of metric and time horizon for technology evaluations is likely to change the rank order of preference, as demonstrated herein with the use of natural gas as a shipping fuel *versus* alternatives. It is not advisable or conservative to use only a short time horizon, *e.g.* 20 years, which disregards the long-term impacts of CO_2 emissions and is thus detrimental to achieving eventual climate stabilisation. Recommendations are made for the use of metrics in 3 categories of applications. Short-term emissions estimates of facilities or regions should be transparent and use a single metric and include the separated contribution from each GHG. Multi-year technology assessments should use both short and long term static metrics (*e.g.* GWP) to test robustness of results. Longer term energy assessments or decarbonisation pathways must use both short and long-term metrics and where this has a large impact on results, climate models should be incorporated. Dynamic metrics offer insight into the timing of emissions, but may be of only marginal benefit given uncertainties in methodological assumptions.

Environmental significance

Methane emissions are a key contributor to climate change but have a substantially different impact on global warming than carbon dioxide: methane has a much high radiative efficiency but is relatively short-lived. Consequently, the use of Global Warming Potentials over a single 100 year time frame has been frequently called into question as it hides the substantial variation in impact over time. This study compares a comprehensive range of different climate metrics and their key qualities to provide an insight on which metric and time horizon is most appropriate for use in different applications.

1. Introduction

Methane emissions are the second largest contributor to climate change next to carbon dioxide, with its direct impact representing around 20% of additional climate forcing since 1750 according to the Saunois *et al.*[1] Further, the estimated direct and indirect forcing effects of methane (including oxidation to CO_2 and impact on ozone creation) is estimated to be 58% of the value of CO_2 (0.97 W m^{-2} for methane compared to 1.68 W m^{-2} for CO_2).[2] Annual emissions are only 3% w/w of those associated with CO_2 (0.56 $GtCH_4$/year *vs.* 14.5 $GtCO_2$/year for methane and CO_2 respectively),[1,3] but methane has a radiative forcing approximately 120 times more than CO_2 immediately after it is emitted. On the other hand, methane has a perturbation life of only 12.4 years,[2] whereas CO_2 lasts in the atmosphere for much longer: 50% of an emission is removed from the atmosphere within 37 years, whilst 22% of the emission effectively remains indefinitely.[4] Consequently, the relative impact of methane compared to CO_2 changes over time.

[a]Department of Chemical Engineering, Imperial College London, UK, SW7 2AZ. E-mail: p.balcombe@imperial.ac.uk
[b]Sustainable Gas Institute, Imperial College London, UK, SW7 1NA
[c]Department of Earth Sciences and Engineering, Imperial College London, UK, SW7 2BP

Global warming potentials (GWP) are used to compare the relative impact of different greenhouse gases (GHGs) on climate forcing, by converting emissions into 'CO_2 equivalents'. It is defined as the average (time-integrated) radiative forcing of a pulse emission over a defined time horizon, compared to CO_2. GWP is used widely across industrial, regulatory and academic applications to compare the effect of a change in product or process. The 100 year time horizon is most common, giving a CO_2 equivalent value of 28–36 for methane (depending on whether various indirect climate effects are included).[2] However, there is much criticism about the use of GWP, because:

- The selected time horizon has a large impact on the value of the metric;
- Despite its name, it does not compare gases against their effect on global temperature;
- Measures an average climate forcing effect of a single pulse emission over time but gives no indication of the climate impact at an end-point in time, or that of a sustained emission.

Increasingly there are calls for the use of different time horizons (*e.g.* 20 years) or even different metrics that better reflect climate change or align with climate targets (*e.g.* the global temperature change potential as described in the IPPC AR5 [2]). But which metric is most appropriate for different applications and over what time horizon?

Previous studies have assessed the impacts of a small selection of alternative metrics on natural gas *versus* coal for electricity[5] and the climate impacts of transportation.[6] Deuber *et al.*[7] and Johansson[8] examine the physical basis and relationship between some metrics, whilst others assess the cost of emissions mitigation using different metrics.[9,10] Mallapragada and Mignone[11] classify a selection of metrics based on some key characteristics and apply metrics to a case study of natural gas *versus* gasoline-fuelled vehicles.

This paper goes further by assessing a large suite of climate metrics regarding their key differentiating characteristics and applies a case study technology assessment to demonstrate the impact of metric selection on technology preference. The study makes recommendations for which metrics and time horizons are most appropriate for different applications, including short term regional emissions estimates, life cycle technology assessments and energy systems pathways.

The contribution this paper makes is to provide insight for industry, policy makers and academics to ensure the appropriate use of metrics. A range of metric values and methods are presented and synthesised, and clear guidelines are given for the use of metrics across different applications.

First, the report describes the procedure for assessment for the climate metrics. Section 3 gives a summary of the climate impact of GHGs and methane in the atmosphere. Section 4 describes the global warming potential metric, including its history and limitations. Alternative metrics are defined in the following Section 5 and key differences and factors that affect the choice of metrics are outlined in Section 6. Evidence around the impact of using the various metrics are described in Section 7, before recommendations and conclusions are made.

2. Assessment methods

Given the purpose of this study is to assess the impact of using different climate metrics and to make recommendations for their use in different applications, the following stages of assessment are undertaken:

- Contextualising the climate cause–effect chain.
- Assessing climate metrics and key characterising factors.
- Applying a case study.

To place the analysis of different climate metrics in context, the study first describes the climate cause–effect chain, against which metrics will be categorised and assessed. Methane is the focus of this study and is explained in this context, but it should be noted that the assessment is applicable for the study of other emissions and environmental impacts.

A review of a full suite of proposed climate change metrics is then carried out. Firstly, the standard GWP metric is defined and characterised relating to its physical basis, methodological construction and associated uncertainty. Alternative metrics are synthesised from a wide body of literature and compared against GWP and each other, relating to their 'CO_2 equivalent' quantities as well as their basis for construction, intuitiveness and associated uncertainty. Key characteristics are developed and analysed against typical applications of each metric. Characteristics considered are:

- The time horizon or associated discount rates;
- The physical/economic basis of the metric;
- Static *versus* dynamic metrics;
- The level of uncertainty *versus* tangibility; and
- The suitability of metrics for different applications.

To demonstrate the impact of the broad range of metrics and CO_2 equivalent values, a case study is given: a climate assessment of the use of LNG as a shipping fuel, against alternative fuels. The case study is based on the outputs of a full environmental assessment, but focuses on the change in rank preference of fuel based on different CO_2 equivalents, as well as the use of dynamic *versus* static metrics.

Different applications of metrics from industry, policy and academic are characterised in terms of factors such as their required simplicity and their time-frames of consideration. From this, a series of recommendations for the use of metrics are made, which may serve as guidelines for further discussion.

3. Greenhouse gases and the climate cause–effect chain

The link between GHG emissions, climate change and damage to human health and ecosystems is multifaceted. Fig. 1 illustrates a simplified cause–effect chain linking emissions with climate change-related damage, and later in this report the metrics will be placed in this context. Firstly, a GHG is emitted, which increases the concentration of this GHG in the atmosphere. Each GHG has a radiative efficiency, which is the capacity of an atmospheric concentration of gas to trap and re-radiate heat downwards, measured in W m^{-2} ppb^{-1}.[2] When multiplied by the atmospheric concentration, this gives the

Fig. 1 The cause–effect chain linking greenhouse gas emissions to climate change-related damage.

total radiative forcing attributed to the GHG. Thus, radiative forcing is the total change in heat balance in the atmosphere from the increase in concentration of a greenhouse gas,[5] measured in W m^{-1}.[12]

An increase in radiative forcing results in a temperature increase, where the degree of temperature rise is governed by the magnitude of emission and radiative efficiency, as well as the existing atmospheric concentration of the GHG and the concentrations of other gases in the atmosphere. The increase in global average temperature causes damage *via* increased extreme weather events, sea level rise, oceanic circulation changes, species extinction and more. This damage is likely to increase faster than the rate of change in global temperature.[13]

Two important points require emphasis. First, increased radiative forcing is not the same as temperature increase. Temperature change is a result of increased forcing, but the value of temperature change is governed by other factors as well. There is also a lag between radiative forcing and temperature change of approximately 15–20 years,[14] as shown in Fig. 2. Second, global average temperature change is not the only indicator that may describe climate change. Other important factors describe climate change, including the rate of temperature rise and the cumulative temperature rise. Each of these climate change attributes are interrelated but cause damage to health and ecosystems in different ways, examples of which are described in Table 1. The global average temperature rise increases the variation and volatility of temperatures and results in more extreme weather events. The rate of temperature increase governs how much time species may take to adapt to new conditions and so a fast rate will cause more species extinction. The cumulative temperature rise (*i.e.* prolonged increases) strongly affects longer term changes such as glacial melt and seal level rise. Emissions of GHGs affect each of these climate attributes differently, depending on: emission quantity; existing concentration of pollutant in the atmosphere; residence time of emission in the atmosphere; and the concentration of other molecules in atmosphere (*e.g.* OH^- and O_3).

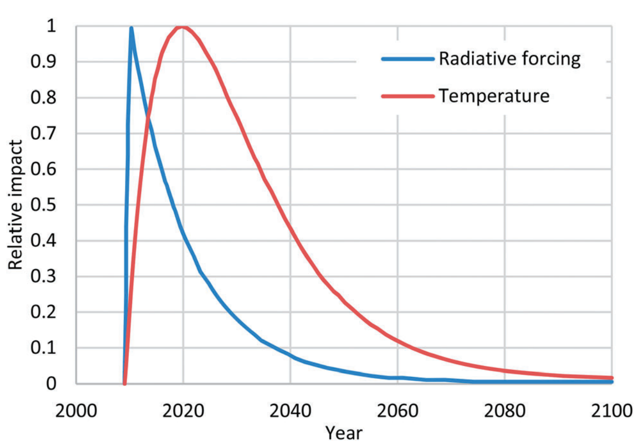

Fig. 2 The relative impact of a pulse emission of methane on radiative forcing and subsequent impact on temperature change. Source: ref. 14.

For methane, an emission has a much larger radiative forcing effect than CO_2 given the difference in radiative efficiency and indirect impacts.[4] However, methane is a short-lived climate pollutant (SLCP) and has an atmospheric lifetime of 8.4 years, defined as the atmospheric burden divided by the sink strength.[15]

Methane comes out of the atmosphere and troposphere by typically reacting with hydroxyl radicals, oxidising to form CO_2 and water (which are also both greenhouse gases). 88% of the methane reacts this way, meaning that one gram of methane will form 2.4 grams of CO_2.[13] The other 12% of the methane forms molecules such as methanal (formaldehyde) and methyl hydroperoxide. The increasing concentration of methane in the atmosphere reduces the availability of the hydroxyl radicals for further reactions which in turn would increase the lifespan of methane. Thus, the perturbation lifetime of methane, which allows for the gases influence on other atmospheric species during its life, is 12.4 years.[2]

In comparison, the lifespan of CO_2 is more complicated due to the different mechanisms that take CO_2 out of the atmosphere, but 50% of a pulse emission is removed from the atmosphere within 37 years, whilst 22% of the emission effectively remains indefinitely.[4] Thus, whilst the initial radiative forcing is low compared to methane, the lasting and cumulative effects are large. The change in radiative forcing over time is shown in Fig. 3 for methane and CO_2.

The effect of GHG emissions on the climate is multifaceted and detailed climate models are required to understand the effects of changing emissions and the environment over time. Such models as MAGICC6 [17] are used in integrated assessment projects to estimate the impacts. However, these are detailed

Table 1 Climate change attributes and resultant damage. Sources: ref. 5 and 14

Climate change measure	Damage
Temperature increase	Extreme weather events
	Heat waves
	Coral bleaching
Rate of temperature rise	Species extinction
Cumulative temperature rise	Sea level rise
	Glacial melt
	Ocean circulation change

global models that require many environment-related assumptions. Simpler, faster approaches are often required to compare the effect of changing processes or technologies in studies such as industrial emissions measurements, policy-related emissions strategies and environmental life cycle assessments. This is the role of climate metrics, to compare technologies, products and policy pathways simply and effectively.

4. Global warming potential

Global warming potential (GWP) is the standard metric used to compare GHGs emitted from different products and services. The metric was developed for use following the Kyoto Protocol and adapted by the Intergovernmental Panel on Climate Change[18] to help in the design of emissions strategies, accounting for the trade-offs between different types of GHG.[19] It is defined as the time-integrated radiative forcing of an emission pulse of a gas, relative to that of CO_2, over a defined time horizon.

For a 100 year time horizon, methane GWP is 36 $gCO_{2eq.}$/gCH_4, meaning that the average radiative forcing of a methane emission over 100 years after the emission is 36 times that of an equivalent mass of CO_2. The IPCC have typically given estimates of GWP for time horizons of 20, 100 and 500 years (although the most recent 5th assessment report excluded 500 years) and the 100 year GWP (GWP100) remains the most common metric used.

With a high radiative efficiency and short lifetime compared to CO_2, methane has a much higher GWP over short timescales: GWP20 is 87 $gCO_{2eq.}$/gCH_4. Fig. 4 shows the GWP of methane over different timescales, but not including the effect of climate-carbon feedback (CCFB), resulting in slightly lower numbers than those expressed within this paragraph (*e.g.* a GWP100 of 30 rather than 36).

The values of GWP for each GHG have been developed over each IPCC assessment report, to account for better understanding of radiative forcing and the various indirect radiative forcing effects, such as cloud albedo and CCFB.[2,21] CCFB is a broad term that encompasses both negative and positive feedback effects associated with increased forcing or temperature. For example, a positive feedback is an increase in temperature causing greater concentrations of water vapour, which itself results in further radiative forcing. The cloud albedo effect is the impact of clouds reflecting radiation and contributing to climate cooling. The concentration of GHGs in the atmosphere and troposphere has an impact on cloud formation and consequently the cloud albedo effect. Additionally, most atmospheric methane eventually oxidises into CO_2, which raises the total GWP values by 1 and 2 for 20 and 100 year time horizons, respectively. This is summarised in Table 2, presenting the change in GWP for methane across IPCC publications.

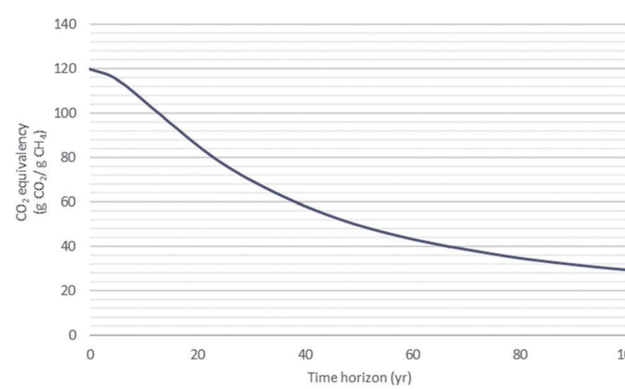

Fig. 4 Illustration of the changing GWP of methane over time. Sources: ref. 20 and 12, using GWP factors without climate-carbon feedback effects.

Table 2 Changes to GWP and perturbation lifetime of methane in IPCC assessment reports. Source: ref. 2, 18, 19, 22 and 23

					Effect included[c]		
Publication	Year	Lifetime (years)	GWP (20 year)	GWP (100 year)	T-O_3	S-H_2O	CCFB
1st AR	1990	10	63	21	✗	✗	
2nd AR	1995	12.2 ± 3	56	21	✗	✗	
3rd AR[a]	2001	12	62	23	✗	✗	
4th AR[b]	2007	12	72	25	✗	✗	
5th AR without CCFB	2013	12.4	84	28	✗	✗	
5th AR with CCFB	2013	12.4	86	34	✗	✗	✗
5th AR with CCFB and oxidation	2013	12.4	87	36	✗	✗	✗

[a] CO_2 AGWP revised down in AR3 leading to relative increase in GWP for other gasses including methane. [b] CCFB included for calculation of CO_2 AGWP. [c] T-O_3 – tropospheric ozone. S-H_2O – stratospheric water vapour. CCFB – climate-carbon feedbacks.

Additionally, indirect effects have been inconsistently included in historical IPCC publications. In the second and third assessment reports calculations of GWP did not include CCFB. In the fourth assessment report, CCFB were included in the calculation of CO_2 absolute global warming potential (AGWP), the baseline against which the GWP for other gases is based. However, while CCFB also impacts on the radiative forcing of other gasses, these impacts were not included in the GWP calculations until AR5, which results in a large increase, especially for the 100 year horizon GWP, as shown in Table 2.

4.1 Criticism of GWP

There are a number of criticisms levelled at the use of GWPs relating to the three key aspects of this metric: a time horizon must be set; it is modelled on a single pulse emission; and it measures time-integrated radiative forcing.

First, the need to select a time horizon requires the metric user to decide a timeframe that is important. This is a particular issue for methane given that the GWP values change so significantly over time. The selection of a single time horizon is arbitrary and means that other timeframes are disregarded: selection of a short timeframe for methane will ignore the long-term impacts of CO_2, whereas selection of a long timeframe for methane will largely ignore the short term forcing of methane. Indeed, the fact that any time horizon is set means that longer term impacts are systematically underrepresented.

Second, the GWP was designed to equate pulse emissions, *i.e.* one-off emissions, rather than sustained or developing emissions, such as those modelled using life cycle assessment methods. This does not generally reflect the consequences of real-world investment or policy decisions.[12]

Last, the physical basis of the GWP is the integrated radiative forcing and does not represent the temperature (or other climate) impact. As described in Section 3, radiative forcing is a precursor to temperature change, but they are not synonymous. Additionally, the fact that GWP is based on an integrated measure means that the GWP indicates the average impact over a time horizon rather than the impact at the end-point of the time horizon (both are useful in estimating the impacts of climate change).

The limitations associated with GWP have given rise to the creation of alternative climate metrics over the last 20 years. These metrics are defined in the following section, after which their key differentiating factors are discussed in Section 6, including time horizons and physical basis.

5. Alternative metrics

The many climate metrics that have been proposed in the last few decades can be categorised in a number of ways, which are summarised in Table 3. Table 3 lists the most cited metrics and categorises them based on key factors: CO_2 equivalency value, their physical basis, whether they are static or dynamic metrics, cumulative or end-point estimates, and their level of uncertainty. The following section firstly describes the most used alternative, GTP, before outlining the characteristics of each other metric in order that they appear in the table.

5.1 GTP – global temperature change potential

Global temperature change potential (GTP) is the most popular and most researched alternative climate metric to GWP.[2] It was developed by Shine *et al.*[24,32] and is included in the IPCC Assessment Reports. It is defined as the change in mean surface temperature after a specified time due to a pulse emission, relative to the effect from an equivalent pulse emission of CO_2. The key differences compared to the GWP are:

• It is an end-point metric,[11] measuring the impact at the end of a time period, rather than a cumulative effect within a time period; and

• It estimates the effect on temperature, rather than radiative forcing (which gives rise to temperature but the relationship is not linear).

Values of GTP for methane are currently estimated as 13 $gCO_{2eq.}/gCH_4$ (GTP100) and 71 (GTP20) including an allowance for CCFB and the eventual oxidation of methane into CO_2. Whilst the GTP20 is around 20% lower than the equivalent GWP20 (87), the 100 year time horizon differs greatly, over 60% lower than GWP, as shown in Fig. 5. This is because the GTP figure measures at the end-point and does not account for the strong forcing prior to this time. At 100 years the proportion of the pulse emission remaining in the atmosphere is

Table 3 Climate metrics relating to methane and their key attributes. Source: ref. 2, 4, 12, 14, 16 and 24–30

Metric	Full name	Source	Time horizon/end-point value 20	100	500	Indicator type	Static/dynamic	Emission type	Time frame	Uncertainty
GWP	Global warming potential[a]	IPCC 2014 (ref. 31)	84–87	28–36	8–11[b]	Radiative forcing	Static	Pulse	Cumulative	Lowest
SGWP	Sustained-flux global warming potential	Neubauer 2015 (ref. 4)	96	45	14	Radiative forcing	Static	Sustained	Cumulative	Lowest
ICI	Instantaneous climate impact	Edwards 2014 (ref. 16)	43	0.1	—	Radiative forcing	Dynamic	Sustained	End-point	Low
CCI	Cumulative climate impact	Edwards 2014 (ref. 16)	86	34	—	Radiative forcing	Dynamic	Sustained	Cumulative	Low
TWP	Technology warming potential	Alvarez 2012 (ref. 12)	—	—	—	Radiative forcing	Dynamic	Sustained	Cumulative	Low
GTP	Global temperature change potential	Myhre 2013 (ref. 2)	71	13	—	Temperature change	Static	Pulse	End-point	Low
IGTP	Integrated global temperature change potential[c]	Peters 2011 (ref. 6)	96	38	12	Temperature change	Static	Pulse	Cumulative	Low
TEMP	Temperature proxy index	Tanaka 2009 (ref. 29)	—	39	—	Temperature change	Static	Pulse	Cumulative	Low
CCIP	Climate change impact potential	Kirschbaum 2014 (ref. 14)	—	32	—	Temperature change; rate of change; cumulative change	Static			Medium
GSP	Global sea level rise potential	Sterner 2014 (ref. 28)	78	18	3.8	Sea level rise	Static	Pulse	End-point	High
IGSP	Integrated global seal level rise potential	Sterner 2014 (ref. 28)	95	39	11	Sea level rise	Static	Pulse	Cumulative	High
GPP	Global precipitation change potential	Shine 2015 (ref. 30)	120	8.1	—	Precipitation	Static	Pulse	End-point	High
GDP	Global damage potential	Kandlikar 1995 (ref. 25)	—	—	—	Economic	Static	Pulse	Cumulative	Highest
GCP	Global cost potential	Manne 2001 (ref. 27)	—	—	—	Economic	Static	Pulse	End-point	Highest
SCM	Social cost of methane	Shindell 2017 (ref. 13)	—	—	—	Economic	Static	Pulse	Cumulative	Highest

[a] Range of values for GWP represents various additional inclusions for carbon climate feedback and oxidation of methane into CO_2. [b] The 500 year value is not given in the most recent IPCC assessment report, so the figure presented is from the 4th assessment report. [c] The IGTP metric values are estimated to be 12% higher than equivalence GWP values and are thus calculated. The original estimation was based on the 4th assessment report values of the GWP.

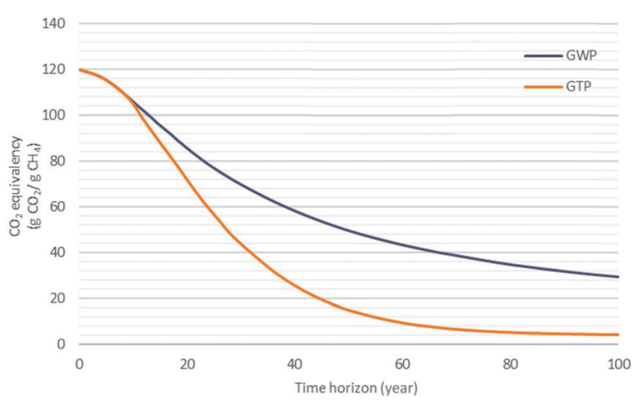

Fig. 5 The global temperature change potential of methane compared to the global warming potential, CO_2 equivalencies across different time horizons. Note, indirect carbon climate feedback and methane oxidation effects are not included within these estimates. Source: ref. 33.

relatively small. Indeed, at this time after the emission, the dominant force is from only the indirect effects such as CCFB and methane oxidation (without which the GTP100 would be only 4).

The GTP goes one step further down the cause–effect chain (see Fig. 8) than GWP by estimating the relative temperature change resulting from the increased radiative forcing. This brings more clarity when using the metric for temperature-based analyses (*e.g.* keeping global temperatures below 2 °C). However, the estimation of GTP incorporates additional assumptions about physical processes, such as climate sensitivity and the exchange of heat between the atmosphere and the ocean.[2,24] This consequently brings more uncertainty compared to GWP.[4] The IPCC estimate an uncertainty of GTP100 of ±75% (with a 90% confidence), compared to ±30% and ±40% for GWP20 and GWP100, respectively.[2]

5.2 SGWP – sustained-flux global warming potential

The sustained-flux global warming potential (SGWP) has been previously called the step-change global warming potential[4,34] and is designed to eliminate the dependence of the GWP metric on the single 'pulse' emission. This metric measures the relative radiative forcing of a sustained emission of a GHG relative to that of CO_2. This metric is otherwise the same as GWP, but the sustained emission measurement results in a larger CO_2 equivalence and is 40% higher than GWP for the 100 year horizon.[4]

5.3 ICI and CCI – instantaneous and cumulative climate impact

Edwards and Trancik[16] developed a new set of metrics in 2014, intended to be a simplified dynamic method to account for changing emissions profiles over time, in order to assist with development of effective emissions pathways. Instantaneous climate impact (ICI) measures the radiative forcing associated with emissions at a specific time point, similar to an instantaneous version of GWP. It is dynamic in that the time horizon end-point is fixed, rather than the time period after an emission (further explained in Section 6). Consequently, in a multi-year emissions assessment (*e.g.* a life cycle assessment), as the year of emission increases, the time period decreases until the end time point is reached. The result is that any methane emissions incurred at the start of the time frame contributes relatively little, but the values increase significantly as the emissions approach the end-point.

The second of the set of impacts developed by Edwards and Trancik[16] is a cumulative version of the ICI, the CCI. As such, it measures the cumulative radiative forcing of an emission or emission profile. It is similar to the GWP in that it measures cumulative radiative forcing, but whereas the time horizon is fixed with GWP (*e.g.* 100 years), the end point is fixed with CCI (*e.g.* 2080). In other words, the CCI is a dynamic version of GWP.[11]

5.4 TWP – technology warming potential

Technology warming potential (TWP) is designed specifically for comparing technologies or products over variable time and is classed as a dynamic metric.[12] TWP does not produce a CO_2 equivalency metric as such, but produces a 'technology equivalency', as it gives relative improvements (or otherwise) associated with technology switching over a time frame. It is defined as the relative proportional change in cumulative radiative forcing over different timescales and may be as a result of a pulse or sustained emission.[5] The effect is broadly similar to the ratio of GWPs associated with two different technologies, but the initial set-up of TWP did not allow for climate carbon feedbacks, suggesting that the methane impact may be underestimated in this metric.[5]

5.5 IGTP – integrated global temperature change potential

The integrated global temperature change potential (IGTP) is a cumulative version of the GTP. Unlike the GTP which estimates the temperature impact of a pulse emission at a specific time, the IGTP estimates the cumulative temperature impact from the time of a pulse emission to a specific time horizon, relative to CO_2.[6] In this respect, it is a temperature equivalent of the global warming potential. This means that IGTP values are higher than GTP, as the initial high radiative (and temperature) forcing is effectively 'remembered' in the cumulative time horizon estimates.[26,28] Values are approximately 12% higher than the GWP for the 20, 50, 100 and 500 year time horizons.

5.6 TEMP – temperature proxy index

The temperature proxy index (TEMP) was developed by Tanaka *et al.*[29] in 2009 to provide a temperature based equivalency metric similar to the GTP but integrated over a specific time horizon (similar to the IGTP). Instead of a projected impact metric derivation such as the GWP, TEMP values are numerically estimated based on the historical contribution of different GHGs over the post-industrial time period.[30] The TEMP metrics and analysis suggest that GWP100 underestimates the contribution from methane and that a value of 39 would be most appropriate (which is not dissimilar to the current GWP100 value of 36 including carbon climate feedbacks and oxidation to CO_2).

5.7 CCIP – climate change impact potential

The climate change impact potential (CCIP) metric was created by Kirschbaum[14] in 2014 and is the only mid-point type metric that combines the effects of temperature rise with cumulative warming as well as rate of warming. Key assumptions associated with this metric are that each impact (temperature, cumulative temperature and rate of rise) are weighted equally in importance and the values are only available for 100 year time horizon, which is similar to the GWP100 at 32 $gCO_{2eq.}/gCH_4$.

This is a unique metric in its attempt to incorporate the different types of climate impact. If there were a specific calculator that allowed the selection of weighting and time horizon to generate the appropriate CO_2 equivalence, this would be a useful bridge between simple static metrics and more complicated climate models.

5.8 GSP and IGSP – global sea level rise potential

The global sea level rise potential was developed in 2014 and goes a step further than the temperature impacts of emission by estimating the specific impact on sea level rise.[28] It is a static metric based on a set time horizon, estimating the relative change in sea level at the end of the time horizon. The values for 20, 100 and 500 year time horizons lie between those associated with GWP and GTP for methane, at 78, 18, 3.8 $gCO_{2eq.}/gCH_4$ respectively.[28] The relative uncertainty associated with GSP is likely to be higher than GWP or GTP as it is further in the line of damage estimation (see Fig. 8). However, this is still a physical metric with no required socio-economic evaluation, unlike the GDP and GCP.

The IGSP is a cumulative version of the GSP, similar to the GWP but estimating average sea level impacts. The metric values for IGSP are slightly higher than those of GWP at 95, 39 and 11 $gCO_{2eq.}/gCH_4$ for 20, 100 and 500 year horizons respectively.

5.9 GPP – global precipitation change potential

Global precipitation change potential is a static equivalency metric created in 2015 that compares GHGs against their effect on global average change in precipitation, due to a pulse or a sustained emission.[30] The precipitation estimate over time uses both a radiative forcing element (GWP) and a temperature change element (GTP) and their relative impact changes over time.[26] Similar to the sea level rise metric, this metric goes further along the cause and effect chain, whilst still being physically based (rather than socio-economic). The metric values are higher than GWP and GTP values for the 20 year horizon (120) and slightly lower for the 100 year (8.1). This indicates that the effect of methane on global precipitation change is large in the short term, much larger than the temperature change impact.

5.10 GDP – global damage potential

Global damage potential (GDP) goes beyond mid-point physical impacts to estimate the end-point damages caused by climate change, relating to human health, increased rates of mortality and ecosystem losses, which are aggregated using an economic value.[7] It is still an equivalency metric in that it estimates the relative damage impact of an emission compared to CO_2 and is based on the cumulative impact over time. The end-point economics-based metric removes the requirement to specify a timeframe by setting an infinite horizon and setting a discount rate at which future emissions are discounted against near term emissions. Recently estimated GDP equivalences for methane are between 19 and 100 with a base case of 50 (with an additional outlier of 420, associated with high discount rate).[35] The estimation of an economic value on damage represents significantly higher uncertainty than other mid-point metrics, owing to the additional assumptions that must be made to estimate:

- The damage caused by an increase in concentration (*e.g.* number of extreme weather events, sea level rise, extinction events); and
- The economic value placed on such damage.

The GDP is an intuitively useful method to determine the least-cost mitigation strategy.[25] However, the move from a physical to economic basis and the high uncertainty reduces the transparency and useability of such a metric for many applications and it is typically utilised within an integrated climate-cost model framework.[2]

5.11 GCP – global cost potential

Global cost potential (GCP) is also an end-point economic metric and defines price ratios between GHGs and CO_2 that deliver the least-cost mitigation solutions to meet a specific climate target at a specific time.[2,27] Similar to the GDP, this metric is typically an output from a climate-economic model generating price ratios for different GHG mitigation options using an optimisation model[36] and are not normally used in carbon equivalency-related studies due to their complexity and dependence on system assumptions. Tanaka *et al.*[36] recently estimated GCP values that fit with a 2 °C climate target, resulting in a range of values from 5 to 65 $gCO_{2eq.}/gCH_4$, with a peak at the time of stabilisation around 2060.

5.12 SCM – social cost of methane

The social cost of methane (SCM) is another estimator of the economic costs of damage associated with methane. As indicated by the name, the damages focus on methane rather than the climate effect, as it includes damages associated with air quality and tropospheric ozone creation which has a large impact on crop yield and premature deaths.[13] Impacts are monetised and levelized per tonne of emission, and subsequently compared to the social cost of carbon. Instead of using specific time horizons, the time horizon is infinite and a discount rate is set. Thus, instead of varying values over time horizons, they vary significantly over discount rate: 10% discount rate equates to a CO_2 equivalency of 199; 5–102%; 4–76%; 2.5–42%; 1.4–26%. These values are higher than most other equivalency metrics, partly due to the incorporation of the damage effect of ozone creation.

6. The key factors that differentiate climate metrics

There are many important differentiating factors associated with the climate metrics, which are analysed below to inform recommendations for metric selection. The following section assesses metric in relation to: selecting the timeframe; static *vs.* dynamic metrics; the physical basis; level of uncertainty; simplicity *vs.* tangibility; and suitability for the application.

6.1 Selecting the timeframe

The need to select an appropriate timeframe is the most common criticism of the GWP and has the largest impact on metric value. This variation is shown in Fig. 6, giving equivalencies for different metrics for methane over different time horizons.

There is no single correct time horizon to use: it depends on the perspective and reason for which the estimation is being carried out.[11,26,37–39] The IPCC typically uses a 100 year time horizon (GWP100), being commensurate with the scenario timescales used in its modelling work. However, 20 year time horizons are increasingly used, which can significantly alter results, often leading to disagreement and conflicting conclusions in the literature.[12,40] Using a short-term metric inherently ignores the impact of long term, long-lived forcers (CO_2) and on a systems scale this means prolonging the point at which the globe reaches climate stabilisation. Conversely, a long-term metric inherently ignores the large impact of short-lived forcers (methane), which may cause more rapid temperature increases require more drastic emission reduction measures earlier to meet temperature targets.

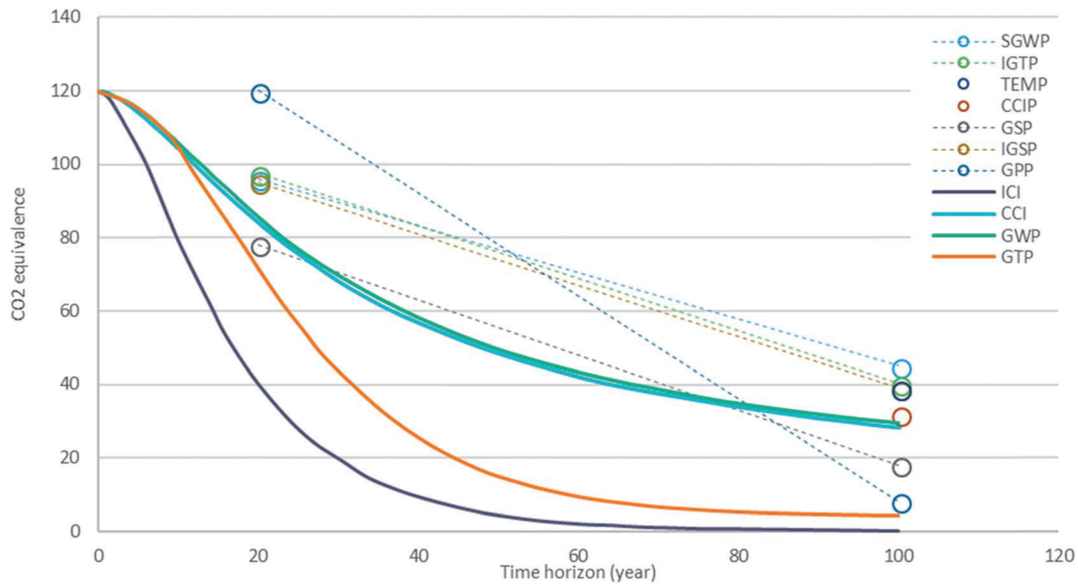

Fig. 6 The CO_2 equivalence of methane using different climate metrics, against the time horizon. Dotted lines are placed between paired values of the same metric where only two points are known. Note, for static metrics the *x* axis denotes the time since the emission and for dynamic metrics CCI and ICI, the *x* axis represents the time away from the end-point stabilisation year (*e.g.* 40 years on the *x* axis means this value is associated with a time horizon of 40 years before the stabilisation period).

Using a GWP100 gives the average radiative forcing occurring over the 100 years after an emission. But why is the average effect over the next 100 years important and are there other important time horizons? The selection of time horizon is a policy decision: are there concerns about short-term or long-term global temperatures? Many countries have committed to reducing GHG emissions by 2030 or 2050, but these are interim targets with the aim of long term decarbonisation. There is an argument to suggest that an appropriate time horizon should be in accordance with 1.5 or 2 °C decarbonisation pathways that require stabilisation of GHG concentrations by 2050–2100 : 30–80 years.[41–43] However, the GWP metric does not measure the impact at a specific time, but the average effect over a period. When concerned with a specific time for stabilisation, an instantaneous metric (such as GTP) may be more appropriate.

As the time of required climate stabilisation grows closer, the importance of methane mitigation grows stronger. Conversely, in 2100, an emission of methane from 2015 will be seen as relatively unimportant. The timeframe after a stabilisation year will also be extremely important in maintaining a stabilised climate, whilst the application of a short time horizon effectively reduces the importance of longer term emissions to zero, which may be inappropriate.

Alvarez *et al.*[12] suggest that for technological environmental analyses, it is most appropriate and transparent to plot estimated GHG emissions over different time horizons. Other studies suggest that a comparison should span a flexible range of time horizons, *e.g.*[12,16] Ocko *et al.*[65] suggest simply presenting GWP from both a 20 and 100 year time horizon. For larger-scale integrated assessment models which project emissions up-to, and beyond, climate stabilisation periods, the use of a single GWP value such as the GWP100 would significantly undervalue the impact of methane emissions. Thus the inclusion of both short and long-term metrics is imperative to assess the robustness of any projections, especially where the contribution of methane emissions is significant.

From the development of metrics that analyse impacts on sea level and precipitation,[28,30] it is clear that potent short lived pollutants like methane may play a strong role in climate change in both the shorter (20 years) and longer (100+ years) time horizons. Both the short term and longer term effects of emissions must be understood and thus the inclusion of multiple time horizons help to prevent any unintended consequences associated with a technology or product switch.

As described in Section 5, there are three metrics described here that do not require the setting of a time horizon, but instead use a discount rate to estimate impacts over an infinite time: the GDP, GCP and SCM metrics. Whilst the avoidance of a time horizon is beneficial, the need to apply a discount rate represents a similar arbitrary weighting of preference for shorter (or longer) time horizons and so there is little advantage from this perspective. The numerical values are even more wide ranging as shown in Fig. 7, perhaps due to the compounding of assumptions relating to discount rates and the cost of damages.

6.2 Physical basis of the metric

The various metrics differ with respect to their physical or socio-economic basis, and are primarily categorised as: radiative forcing; temperature; economic; or a mix of the aforementioned. They can also be categorised in relation to their position along the climate cause–effect chain as shown in Fig. 8. Metrics sitting closer to the end-point effects are more intuitively useful and understandable. As described, GWP is based on radiative forcing, but there is suggestion that a switch from GWP to

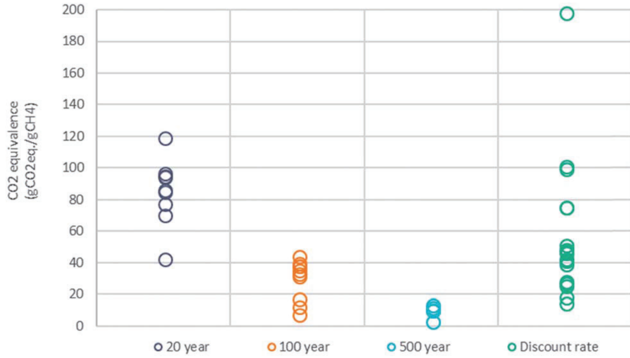

Fig. 7 CO_2 equivalence of methane for different time horizons and compared to metrics which use discount rates instead of time horizons.

a temperature-based metric such as GTP is more appropriate given that our climate targets revolve around global mean temperature changes.[2]

However, at the point in the cause–effect chain where metrics estimate end-point damage, they convert from a physical basis to socio-economic and this carries additional uncertainty. These damage indicators may be extremely useful for broader studies into decarbonisation pathways, but typically require energy/climate/economic system models and are a step away from a simple metric design. The use of simpler physical metrics is preferable for such uses as annual emission inventories from a company or national perspective, or for simpler technological evaluations.

More recent metrics estimating contribution to sea level rise, the GSP, and to precipitation change, GPP, are very useful in improving our understanding of the physical effects of emissions across different timeframes and will help to inform the appropriate CO_2 equivalencies. It is notable that these metrics are broadly within ranges bounded by the GWP and GTP for equivalent time horizons.

6.3 Static *vs.* dynamic metrics

The way that GWP (and GTP) is used in most abatement studies does not take into account the timing of emissions. Typically, one metric (*e.g.* GWP100) is used to estimate emissions, for example from a natural gas well, over the lifetime of the well. However, as a well may be active and emitting for 30 years or more, this means that the end-point of the time horizon is not fixed. For example, if a well emits within the first year of operation, say 2015, the GWP100 would consider the impact up to 2115. If the well still operates and emits at 2045, the GWP100 estimation would consider the impact up to 2145.

Static metrics like the GWP and the GTP use fixed time horizons. This means that the time horizon (*e.g.* 100 years) stays the same length, even when emissions studies may span multiple years (*e.g.* life cycle assessments). However, these metrics may also be used dynamically instead, using a fixed end-point in time rather than a fixed time horizon. This means that for multiple year studies, the end-point (*e.g.* the year 2100) stays the same and the horizon reduces as the year of emission advances. For example, a GWP100 may be used with an emission in 2015, a GWP99 in 2016 and GWP98 in 2017 *etc.*[44] Fig. 9 shows the difference between static (GWP and GTP) and dynamic (ICI and CCI) metrics by defining the CO_2 equivalency value over time.

To use a dynamic approach in a technology assessment, first an end-point must be selected (*e.g.* 100 years from the start of the assessment time). Estimations of emissions must be made for each year of the assessment period (*e.g.* over a 30 year lifetime of a technology). Additionally, a different metric value for each year must be estimated. For example, emissions at year zero will be multiplied by the 100 year metric value, whilst emissions at year one will be multiplied by the 99 year metric value, and so on until the end of the assessment period (*e.g.* emissions at year 30 multiplied by the 70 year metric value). Thus, the use of dynamic metrics adds significant complexity to

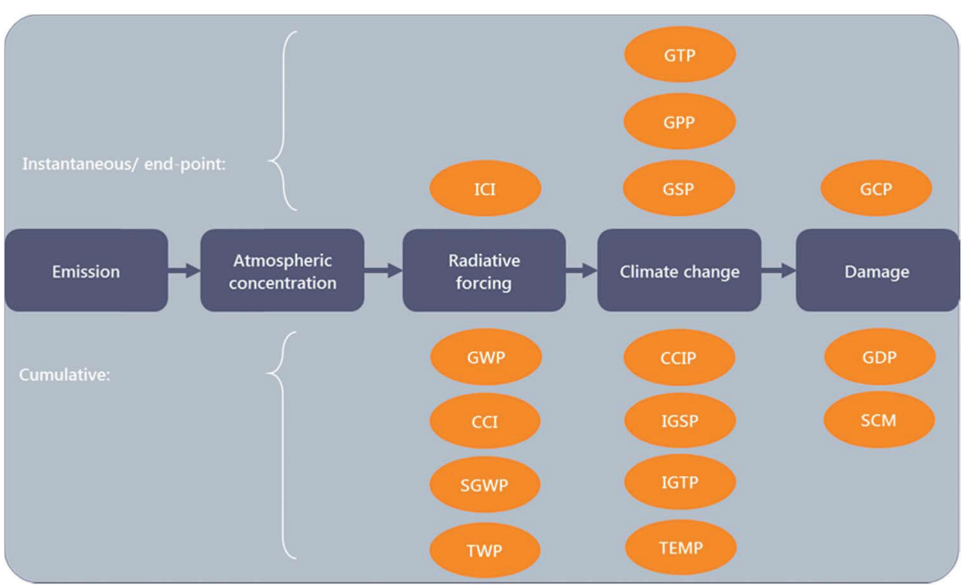

Fig. 8 Climate metrics categorised by: stage in cause–effect chain; whether they indicate instantaneous or cumulative impacts.

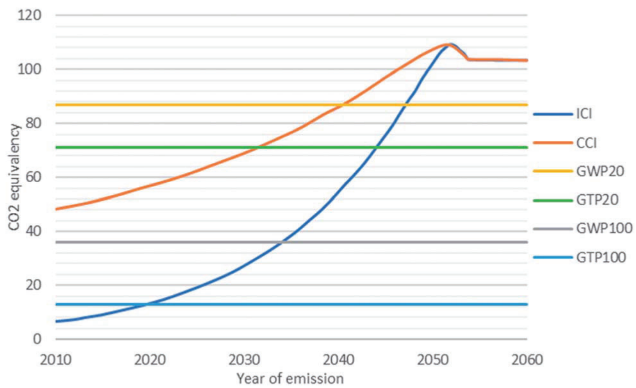

Fig. 9 Comparing GWP, GTP, ICI and CCI metric values over time. ICI and CCI values are dynamic and are set to an end-point of 2059, as per Edwards and Trancik,[16] giving an equivalent initial time horizon of 49 years.

the calculation relative to static metrics. Applications of the use of dynamic metrics in environmental studies include Levasseur *et al.*[44] and Edwards and Trancik.[16]

The use of static metrics must be carried out with care for emissions scenarios over long timeframes, for example with life cycle assessments. When doing so, the definition of the metric changes from its original meaning, for instance with GWP, which is intended to measure the average effect of a single pulse emission over a specific time horizon. Both the pulse and specific time horizon aspects are no longer applicable as there may be sustained emissions over many years.

The use of a dynamic metric may result in significantly different results compared to the use of static metrics.[16] Using the example above, the methane emissions during the first year would have a significantly lower impact on global warming than equivalent methane emissions during the 30th year. Such metrics are the ICI[16] or a dynamic version of the GTP.[2]

Whilst the use of dynamic metrics may be preferable when comparing technologies over long timescales, static metrics are most appropriate for emissions estimates based on shorter timescales, for example annual emissions estimates. Additionally, the projection of a specific stabilisation year for use with a dynamic metric is an assumption, with atmospheric GHG concentration stabilisation years spanning 40 years or more across different emission pathways, as mentioned in Section 6.1. Thus, the use of a simpler static GWP for an LCA that spans 30 years would fall within this uncertainty range. Thus, there may be only marginal benefit in applying a dynamic metric methodology, which may be outweighed by the relative increase in complexity of calculation.

6.4 Simplicity *vs.* tangibility

As metrics move along the cause–effect chain, they become more policy relevant[2] and relatable as an output. For example, temperature change may be a more tangible measure than radiative forcing, whereas damage estimates as a result of climate change are even more so. However, with greater tangibility comes more assumptions, uncertainty and complexity. For example, moving from a physical temperature change to estimating the socio-economic damage caused by that temperature change requires the modelling of climate impacts, population and demand projections, as well as technological resilience and innovation. Thus, there is a trade-off between simplicity, uncertainty and tangibility.

Myhre *et al.*[2] show that uncertainty is higher for GTP than for GWP for example: ±40% for GWP100 compared to ±75% for GTP100 (with a 90% confidence interval). However, the impact of different time horizons gives even more variation in results than this uncertainty. Further, the uncertainty in estimates of methane emissions in the first place have relatively high uncertainties in some cases *e.g.*,[51] which are likely to be of similar order of magnitude to those from GWP or GTP. Some uncertainty is to be expected, which is why sensitivity analyses should be carried out wherever an investment or policy decision is marginal or at risk. It is the authors' opinion that for technology assessments and annual emission inventory estimates, physical climate metrics that enable CO_2 equivalency over a broad range of values best serve the purpose of understanding the range of potential climate impacts.

6.5 Suitability for application

Perhaps most importantly, the chosen metric must be appropriate for the application. Different applications require different levels of complexity and span different time scales as shown in Table 4. Typical uses of climate metrics are:

- Emissions inventories from industry operations.
- National/regional emissions contributions.
- Technology assessments *e.g.* LCA for policy planning.
- Energy system mitigation pathways.

When the result will inform a long-term investment decision or policy, it is imperative that the impacts of using different metrics and time horizons on the result are explored.

Broadly, estimates of emissions over a short timeframe, *e.g.* annual emissions estimated from a company or national perspective, are likely to require a simple and static metric, given the lack of time variation and the requirement for fast and repeated estimation. For a technology assessment or a life cycle assessment that spans multiple years, a suitable metric may be:

Table 4 Categories of applications for the use of climate metrics, with associated qualities and requirements

Application	Timeframe	Calculation complexity	Static/dynamic	Suitable metrics
Annual estimate: facility/region	~1 year	Low	Static	GWP/GTP/similar
Technology assessments	~20 years	Medium	Static or dynamic	GWP/ICI/CCI/GSLP *etc.*
Decarbonisation pathways	~100 years	High	Dynamic	End-point metrics

a dynamic metric which accounts for the longer time frame considered; and a simple metric, given that the scope boundary is small and does not consider wider global implications. Estimates of emissions pathways to meet climate targets over longer time scales and multiple technologies may require metrics that: estimate the effects of climate change, either physical or economic damage; and may utilise more complex approaches such as climate models or end-point metrics.

7. The impact of different metrics on emissions results

As seen in the summary Table 3, the CO_2 equivalency values of methane range from 4 to 120 across metrics and time horizons. Additionally, the end-point metrics SCM and GDP have even higher values associated with the highest discount rates (for example the SCM estimates an equivalency of 199 at 10% discount rate[13]). It is clear that the time horizon (or discount rate) has the largest impact on variation, more so than the metric type. Given that these are static multipliers in emission estimates, the impact of using different static values is large and linear.

To determine the impact of using different static and dynamic metrics and time horizons, this study applies the various metrics and equivalency values to an emissions case study: an estimate of greenhouse gas emissions associated with the production and consumption of various shipping fuels, including liquefied natural gas (LNG), heavy fuel oil (HFO) and methanol. Multi-year technology or fuel assessments typically use a single metric (*e.g.* the GWP100), but this assessment shows that the use of a singly metric inappropriately ignores the importance of timing of emissions and of the differences between short-term and long-term climate impact.

LNG exhibits 25–30% lower CO_2 emissions than liquid fossil fuels such as HFO upon combustion on an energy output basis, but typically has greater methane emissions.[45–48] Total methane emissions are governed by both the upstream supply chain and the engine type: this study investigates the use of a lean-burn spark ignition (LBSI) and a high-pressure dual fuel (HPDF) engine.[45] HFO and methanol are both used within diesel engines, where methanol also has lower CO_2 emissions due to its relatively higher H–C ratio.[48–50] A full environmental assessment has been conducted and is presented in a parallel paper to this, but a summary of the life cycle CO_2 and methane emissions are given in Fig. 10.

For the natural gas supply chain, upstream methane emissions arise from extraction, gathering and processing, liquefaction, storage and bunkering. Median estimates from Balcombe *et al.*[51] were used for production, gathering and processing. Liquefaction figures were estimated based on mean values derived from 6 studies[52–57] and synthesised in Balcombe *et al.*[58] For LNG storage the study uses assumptions made in Lowell *et al.*,[53] whereas for bunkering, it is assumed that 0.22% of LNG is boiled off or displaced as vapour during fuelling, with a 50% capture resulting in 0.11% emission.[53,59]

For methanol, the production and processing of natural gas is the same as included for the LNG supply chain. The inventory for gas reforming and methanol synthesis is derived from the NREL database,[60] using the Ecoinvent 3.3 database for the ancillary impacts.[61] The upstream allocated impacts to heavy fuel oil and marine diesel oil are taken from the Ecoinvent 3.3 database. For HFO, bunker oil with an average sulphur content of 3.5% w/w is assumed. For diesel, the production of low sulphur light fuel oil is used, with a sulphur content of 0.005% w/w. For upstream carbon dioxide emissions, 440 gCO_2/kg HFO and 524 gCO_2/kg diesel is associated with the production up to point of use.[61]

Engine efficiencies, total methane emissions and total CO_2 emissions are given for each fuel/engine option in Table 5. For engine efficiencies, average values from various sources: ref. 45–48, 53, 62 and 63 were taken and emissions are expressed per kWh of power output considering the average efficiency.

As can be seen in Fig. 10, large differences exist across the options in methane emissions both upstream and at end-use, as

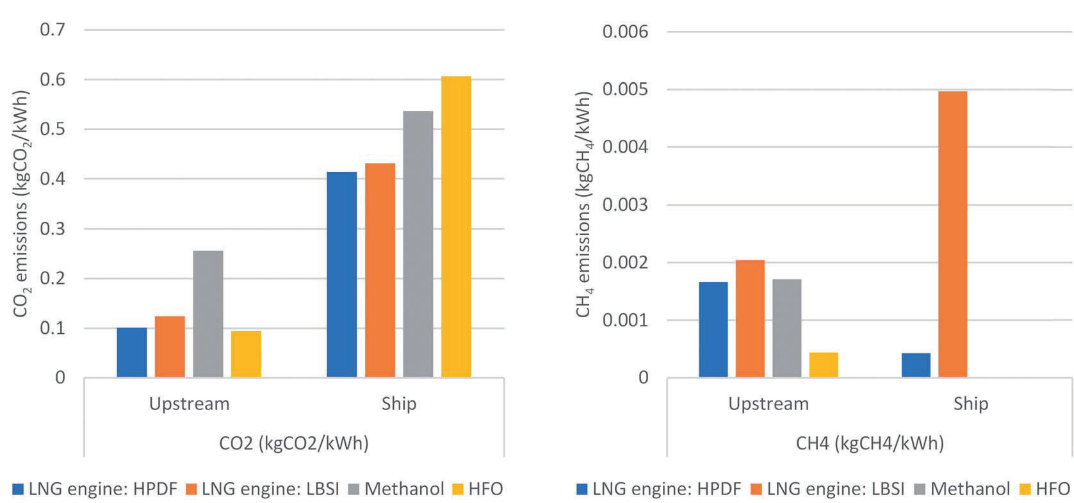

Fig. 10 CO_2 and methane emissions associated with the supply and use of 4 different fuels and engines for ships. Emissions are divided into upstream supply chain and ship usage. Source: ref. 51–61.

Table 5 Summary of inventory of engine efficiencies, methane and CO_2 emissions. Data averages from various sources: ref. 45–48, 53, 62 and 63

	LBSI	HPDF 2-stroke	HFO	MDO	Methanol
Efficiency (% LHV)	45%	51%	45%	45%	45%
Methane (gCH_4/kW h)	4.8	0.3	0.011	0.01	0
CO_2 (gCO_2/kW h)	462.3	427	593.0	524	536.4

well as some moderate variation in CO_2 emissions. Combined life cycle GHG emissions are represented in Fig. 11 for different CO_2 equivalency values assumed. Given the different emission profiles, there exist some crossover points where the rank order of fuels change. Under low equivalency values of less than 20 $gCO_{2eq.}/gCH_4$, both LNG fuelled engines exhibit the lowest GHG emissions. Putting this in context, CO_2 equivalence values of less than 20 are those associated with longer time horizons and end-point metrics which do not account for the high initial forcing impacts. Such metrics with less than 20 $gCO_{2eq.}/gCH_4$ are the GTP at timeframes greater than 45 years, the ICI at timeframes greater than 30 years and the global sea-level rise potential (GSP) and global precipitation change potential (GPP) at 100 year time horizon.

As CO_2 equivalency value increases, the higher methane emissions associated with LBSI LNG engine result in this fuel/engine option exhibiting the highest GHG emissions. Conversely, the LNG fuelled HPDF engine exhibits the lowest impacts across all equivalency values beside the highest at 120 $gCO_{2eq.}/gCH_4$, due to its significantly lower methane slip rates. It should be noted that methanol fuelled engines exhibit higher GHG emissions than HFO across all time horizons due to the high CO_2 emissions associated with methanol production from natural gas, as well as the moderate upstream methane emissions.

To understand the time dependence of emissions, we employ dynamic versions of the GTP and GWP for the above case study. The climate impact of the different fuels varies over time significantly, as shown in Fig. 12. When long time horizons are considered, LNG engines perform favourably, especially in the case of GTP. For GTP and time horizons greater than 40 years, LNG presents a reduced climate impact by 10–20%. However, the LBSI engine with high levels of methane slip performs very poorly with respect to short term climate forcing. With respect to GWP, the integrated nature of the metric means that the initial high climate forcing of LNG engines maintains its impact for the LBSI engine across all timeframes considered, resulting in a higher climate impact than HFO. The HPDF with lower methane slip and low CO_2 emissions has the lowest climate impact across all time horizons.

Two implications arise from this assessment. Firstly, short-term impacts are substantially different to long-term impacts across different technologies and the selection of timeframe may change the rank order of preference. It is imperative that both short and long-term climate impacts are accounted for when considering industrial investment or policy decisions. Secondly, for LNG fuelled engines to reduce GHG emissions compared to HFO, both upstream and end-use methane emissions must be constrained. Engines which inherently exhibit high methane slip are inappropriate for reduction of climate impacts. It should be noted however that LNG offers other benefits than just climate impact, including reduced NO_x, SO_x, particulates as well as cost improvements.

The effect of changing equivalency value on the climate impact of other technology groups is also noticeable. For example, Edwards and Trancik[16] compare the operation of a CNG passenger vehicle *versus* one fuelled with petrol. Using a GWP100 results in the CNG vehicle improving GHG emissions by 10–15%, but with a GWP20 the CNG vehicle exhibits 20% higher emissions than for petrol. Producing a dynamic assessment using ICI and CCI

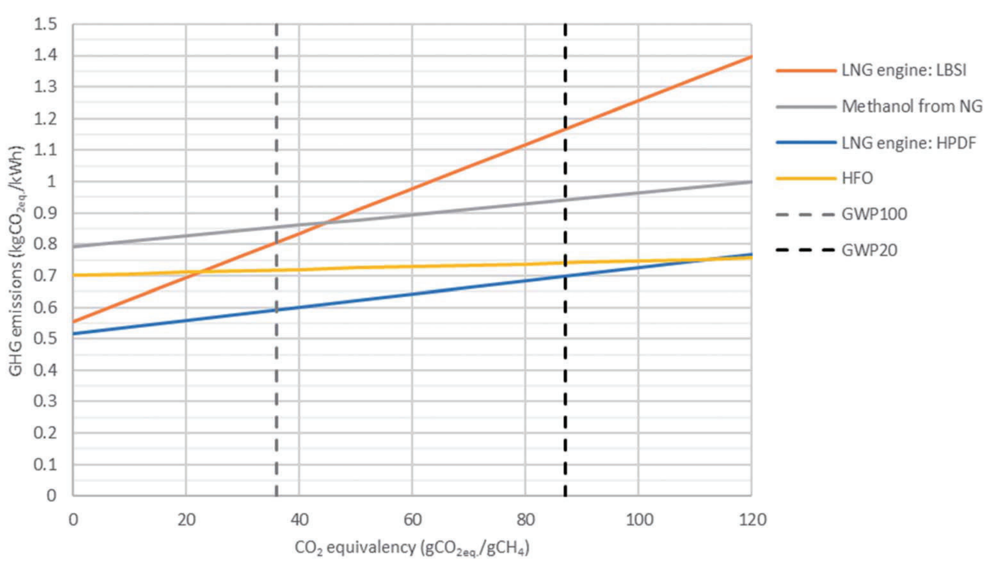

Fig. 11 Estimates of total CO_2 equivalent GHG emissions for different shipping fuels and engines.

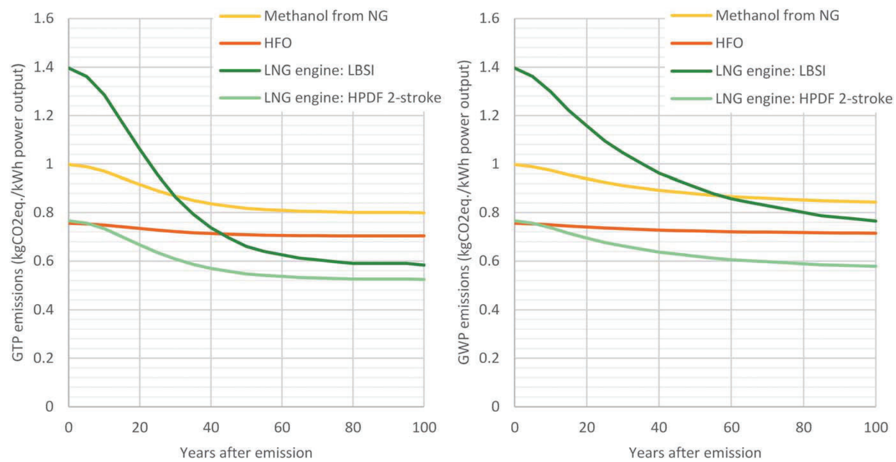

Fig. 12 Life cycle GHG emissions associated with a selection of fuels and marine engine types, expressed for each year after emissions using GTP (left) and GWP (right) metrics.

metrics shows that CNG passenger vehicles offer a climate benefit only over timeframes longer than 20 years.

The comparison of natural gas against coal for power generation is robust in favour of natural gas and shows preference in all but the most conservative of assumptions about GWP values and methane emissions.[64] However, for estimates where carbon capture and storage is used to reduce combustion emissions by up to 90%, the impact of methane emissions proportionally increases. In this case, the choice of metric and time horizon is likely to have a large impact on the relative benefit.

Thus, the selection of metric, and more importantly, time horizon, has a large impact on the ranking of these fuels and technologies, as well as the magnitude of estimates. Investment or policy decisions that trade-off different greenhouse gases like above must ensure that both short-term and long-term climate impacts are taken into consideration.

8. Conclusions and recommendations

This report has investigated the use of various climate metrics and analysed their key attributes and limitations, with respect to methane emissions. There is no single metric or time horizon that is appropriate for all applications and situations. One key point is that methane emissions for the most part are transitory,[33] whereas CO_2 emissions are persistent. Consequently, when considering time horizons the emphasis must not be lost on eliminating CO_2 emissions as, if they are not largely eliminated, the climate will not stabilise. Therefore, any adoption of a shorter time horizon should be tempered with a comparatively longer one.

Given the requirement to stabilise GHG concentrations and to ensure there is no long-term climate change beyond a 2 °C limit, it is inadvisable to use only a 20 year time horizon. A 20 year horizon effectively disregards the impact of emissions after this point, which in the context of comparing methane to CO_2 emissions, dangerously undervalues the long term impact of CO_2. A two-value approach, which indicates the effect over two different time horizons, is suggested by a number of studies.[65]

In selecting an appropriate metric, there is a trade-off between simplicity and transparency.[66] The most appropriate metric depends on the application and which aspect of climate change is most pertinent to the study.[2] Using a single value equivalency such as the GWP100 or GTP100, is the simplest option but hides much information which may be needed to make an investment decision or a policy recommendation. For example, a GHG with a short life but strong radiative forcing may have the same GWP value over a set time horizon as a GHG with a long life but weak forcing effect: the impact of each GHG on climate change may be significantly different but this is lost with such a simplification.[32]

A temperature-based metric such as GTP fits well with a temperature based climate target, but it is suggested that the damage caused by climate change will increase faster than the temperature increase.[13] Consequently, reducing our CO_2 equivalencies from GWP values to GTP values may cause an underestimation of the impact of methane. Even the use of GWP100 may cause an underestimation of the contribution of methane,[16] for example to impacts relating to sea level rise.[28]

The overarching recommendation from this study is to present emissions results with transparency. It is prudent to report methane and CO_2 emissions separately and where climate metrics are used, a summary of the magnitude and type of metric should be given. If the equivalency value has a large impact on results, both low and high values should be used to assess the impact.

Broadly, metric applications can be placed into three categories: short-term (*e.g.* annual) emissions estimates of processes, facilities or regions; multi-year technology assessments or life cycle assessments; and long-term modelling of energy systems and decarbonisation pathways. Recommendations are made for each category.

Estimates of emissions on a short timescale in the order of 1 year typically involve aggregating estimates for a facility or region and require simple static metrics such as GWP or GTP.

Two recommendation options are to: present emissions using a single GWP or GTP metric (50 or 100 year), and include the separated contribution from both methane and CO_2; present two time horizons, a short term (*e.g.* 20 or 50) and a longer term (*e.g.* 100 or more), such that any comparative arguments for technology change holds in both the short term or the long term, or at least that a detriment to either short or long term has been considered.

For technology assessments or life cycle assessments that span 20 or 30 years, suitable metrics could be static (GWP or GTP) or dynamic (*e.g.* ICI or TWP) to account for the emissions timing. However, given the uncertainty associated with a projected stabilisation year, this report considers dynamic metrics to be of only marginal benefit. Additionally, given the increase in complexity associated with using a dynamic metric, the selection of a static metric and incorporating two (or more) time horizons would be appropriate.

For longer term analyses of multiple energy systems over long timeframes, higher levels of complexity are acceptable and application of climate models is most suitable. Where this is not feasible, the application of dynamic metrics or the assessment of both short and long-term time horizons is imperative, especially under scenarios where methane emissions are significant.

In summary, the use of climate metrics in GHG estimation must be carried out with great care and the standard usage of a single global warming potential is not acceptable as it may hide key trade-offs between short and long-term climate impacts. To counter this, transparent reporting of methane and CO_2 emissions is required. It is vital to test any GHG estimates with high and low equivalency values to ensure that we are not simply replacing long-term climate forcing with short-term, or *vice versa*.

Energy, Climate change, Environment

Energy

Methane emissions

The EU methane strategy aims to reduce methane emissions, improve air quality and reinforce the EU’s global leadership in the fight against climate change.

Methane is the second most important greenhouse gas contributor to climate change following carbon dioxide. In fact, methane’s ability to trap heat in the atmosphere is even stronger than that of carbon dioxide.

On a 100-year timescale, methane has 28 times greater global warming potential than carbon dioxide and is 84 times more potent on a 20-year timescale.

According to the International Energy Agency, the annual increase in methane concentration from 2020 to 2021 was the highest on record and real-time data shows that levels continued to increase in 2022. When using fossil gas for electricity generation, lifecycle methane emissions must not exceed 3% of delivered volumes, because in climate terms, it would then be better to use coal for electricity generation. Abating methane emissions is therefore highly relevant to achieving the 2050 climate objectives. Moreover, methane is a potent local air pollutant and contributor to ozone formation, which causes serious health problems.

Key figures on methane

2nd

most important GHG contributor to climate change

60%

of the global methane emissions result from human activity

1/3

of this comes from the energy sector

According to the Climate and Clean Air Coalition (CCAC) Scientific Advisory Panel, reducing methane emissions associated with human activity by 50% over the next 30 years would mitigate against global temperature change by 0.2°C, a significant step towards keeping the overall temperature increase below 2°C.

The International Energy Agency estimates that more than 260 bcm of gas was wasted worldwide in 2021 (https://www.iea.org/reports/global-methane-tracker-2023/overview) due to flaring, venting and leaking and that 47% of those emissions can be mitigated with existing technology through measures, such as leak detection and repair. That gas could contribute to the EU security of supply, greater liquidity and help lower prices. It could also mean that new reserves would not be needed to take us to 2050. Given the market value of the additional gas captured through such measures, 40% of these mitigations would have no net-cost.

EU methane strategy

©European Union

Tackling greenhouse gas emissions is a priority of the European Green Deal.

The EU's methane strategy (COM2020/663), published in October 2020, sets Europe's ambition and aims to curb temperature increases, improve air quality and reinforce the EU's global leadership in the fight against climate change.

It focuses on reducing methane emissions in the energy, agriculture and waste sectors, which account for almost all human-related methane emissions.

This cross-sectoral approach takes targeted action in each area while also promoting synergies across sectors, for example through the production of biomethane.

Regulation on methane emissions reduction in the energy sector

As announced in the EU methane strategy, the Commission adopted on 15 December 2021 a proposal for a regulation aimed at reducing methane emissions in the energy sector.

The provisional agreement was reached *(https://ec.europa.eu/commission/presscorner/detail/en/IP_23_5776)* between the European Parliament and the Council on 15 November 2023. After its formal adoption, it will be published in the EU Official Journal and enter into force 20 days later.

The new legal act will provide for reducing energy sector methane emissions in Europe and in our global supply chains. It aims to stop the avoidable release of methane into the atmosphere and to minimise leaks of methane by fossil energy companies operating in the EU. The new regulation covers

- improved measurement, reporting and verification of energy sector methane emissions
- an immediate reduction in emissions through mandatory leak detection and repair and a ban on venting and flaring practices, which involve the release of methane directly into the atmosphere
- a methane transparency requirement on imports, collecting information on whether and how exporter countries/companies are measuring, reporting and abating methane emissions, with a view to establish a methane intensity profile of those entities

The Commission proposals on measurement and reporting of methane emissions, which build on the Oil and Gas Methane Partnership 2.0 (OGMP 2.0) framework, will help understand the exact locations and volumes of methane emitted, allowing a shift from estimates to direct measurements of methane emissions, checked by independent verifiers. The urgency to tackle methane emissions is reflected in the proposals on mitigation that aim to deliver reductions soon after the legislation will enter into force.

For **oil and gas**, companies would need to frequently survey their equipment to detect leaks. If found, they would need to be repaired immediately, mostly within 5 or 15 working days and monitored to ensure that repairs were successful. The proposal also bans venting and routine flaring, allowing venting only in exceptional or unavoidable circumstances for safety reasons. It allows flaring only if re-injection, utilisation on-site or transport of the methane to a market are not technically feasible, with more restrictive rules for how it can be carried out.

For **coal**, the proposal envisages a phase out of venting and flaring of methane, ensuring that safety aspects in coal mines are accounted for. The proposal also obligates EU countries to establish mitigation plans in the case of abandoned coal mines and inactive oil and fossil gas wells.

Partners and initiatives

As methane emissions transcend national borders, the European Green Deal stresses the need for international collaboration.

Global Methane Pledge

President von der Leyen and President Biden launched the Global Methane Pledge (GMP) at COP26 in Glasgow 2021 to slash methane emissions by 30% by 2030. Since its launch, the GMP has generated unprecedented momentum for methane action. Country endorsements have grown from just over 100 in 2021 to over 150 representing 80% of the global economy, and more than 50 countries have developed national methane action plans or are in the process of doing so.

At the COP28 Global Methane Pledge Summit in December 2023, President von der Leyen presented the first ever EU methane regulation for the energy sector and announced €175 million in funding to methane actions *(https://ec.europa.eu/commission/presscorner/detail/en/ip_23_6057)*. Moreover, she committed to developing a roadmap for COP29 for the global rollout of the "You Collect, We Buy" scheme, whereby the EU incentivises companies to commercialise gas that would otherwise go to waste, announcing that the EU and Algeria would be the first to pilot the scheme.

This video is also available on the EC AV portal. It was produced for COP28 December 2023, and explains the objectives of the Global Methane Pledge.

At the Major Economies Forum in April 2023, the EU joined the **Methane Finance Sprint**, launched by President Biden asking governments to contribute to the goal of mobilising at least $200 million in new methane finance for projects by COP28.

In September 2023, at the occasion of the UN General Assembly in New York, Canada, the Federated States of Micronesia, Germany, Japan, and Nigeria joined the EU and the US as Champions of the Global Methane Pledge.

In June 2022, a **GMP Energy Pathway** was launched at the Major Economies Forum on Energy and Climate to accelerate methane emissions reductions in the fossil energy sector. A **GMP Food and Agriculture Pathway** and **GMP Waste Pathway** were launched in the margins of COP27, where the EU and the US convened a Methane Ministerial to highlight the progress and discuss further implementation steps, including enhanced efforts leading up to COP28.

Joint declaration on reducing GHG emissions from fossil fuels

At COP27 in 2022, the EU also confirmed its commitment on methane emission reduction by endorsing a 'Joint declaration on reducing greenhouse gas emissions from fossil fuels *(https://ec.europa.eu/commission/presscorner/detail/en/statement_22_6827)*', together with the United States, Japan, Canada, Norway, Singapore, and the United Kingdom.

Together they represent 50% of global gas import volumes and over 30% of global gas production. And they aim to take steps to reduce the methane emissions associated with their energy consumption, which can spur emissions reductions across the value chain.

MMRV Working Group

The new International Working Group on measurement, monitoring, reporting and verification (MMRV) was publicly announced on 15 November 2023. It's a follow up action to the Joint Declaration on reducing greenhouse gas emissions from fossil fuels adopted at COP27, where the importance of adopting robust measurement, monitoring, reporting, and verification frameworks at international level was highighted.

The Working Group members include 12 countries, the European Commission and the East Mediterranean Gas Forum (as observer): Australia, Brazil, Canada, Colombia, France, Germany, Italy, Japan, Norway, Republic of Korea, United Kingdom and the United States of America.

It aims to develop a consensus-based approach for the MMRV of greenhouse gas (GHG) emissions across the international supply chain of natural gas, from pre-production through final delivery, to enable the provision of comparable and reliable information as well as to better equip companies with tools to rapidly reduce their GHG emissions.

The Working Group will also advance data accuracy and comparability by building upon well-established and globally recognised frameworks, particularly OGMP 2.0, which today includes over 115 companies with assets in more than 60 countries, representing over 35% of the world's oil and gas production and over 70% of LNG flows.

International Methane Emission Observatory

To help take the issue forward, the Commission supported in 2021 the establishment of the International Methane Emission Observatory (IMEO) together with the UNEP, the Climate and Clean Air Coalition and the International Energy Agency.

Funding from EU Horizon 2020 kick-started the development of the observatory, followed by further contributions from the EU through the Neighbourhood, Development and International Cooperation Instrument (NDICI) and from other partners, such as the Global Methane Hub and Bezos Earth Fund.

The IMEO collects and verifies methane emissions data to provide the international community with an improved understanding of global emissions and where abatement action should be focused. It provides a sound scientific basis for the implementation of the Global Methane Pledge. Its collected data help to prioritize actions and monitor results against commitments made by state actors as well as oil and gas companies.

The IMEO also coordinates the Oil and Gas Methane Partnership 2.0 (OGMP 2.0), the flagship oil and gas reporting and mitigation programme of UNEP. It is the only comprehensive, measurement-based international reporting framework for the sector, which today covers 35% of oil and gas producers and 70% of LNG flows.

In November 2022, at the COP27 in Sharm El-Sheikh, IMEO announced the Methane Alert and Response System (MARS), a satellite-based system to detect methane emissions. It has started through pilots to detect major emissions from the energy sector, and in the future, it will expand to cover other methane emitting sectors, such as waste and livestock.

Climate and Clean Air Coalition

The EU is actively involved in several international initiatives on reducing methane emissions, including through the Climate and Clean Air Coalition (CCAC), established under the United Nations Environment Programme (UNEP). The CCAC works to tackle short-lived climate pollutants such as methane and black carbon in an effort to combat climate change and improve local air quality. In this context, the Commission submitted an EU methane action plan in November 2022 to appear alongside other national plans.

Delaying methane mitigation increases the risk of breaching the 2 °C warming limit

Claude-Michel Nzotungicimpaye [1,2,3✉], Alexander J. MacIsaac[1] & Kirsten Zickfeld [1]

Atmospheric methane levels are growing rapidly, raising concerns that sustained methane growth could constitute a challenge for limiting global warming to 2 °C above pre-industrial levels, even under stringent CO_2 mitigation. Here we use an Earth system model to investigate the importance of immediate versus delayed methane mitigation to comply with the 2 °C limit under a future scenario of low CO_2 emissions. Our results suggest that methane mitigation initiated before 2030, alongside stringent CO_2 mitigation, could enable to limit global warming to well below 2 °C over the next three centuries. However, delaying methane mitigation to 2040 or beyond increases the risk of breaching the 2 °C limit, with every 10-year delay resulting in an additional peak warming of ~0.1 °C. The peak warming is amplified by the carbon-climate feedback whose strength increases with delayed methane mitigation. We conclude that urgent methane mitigation is needed to increase the likelihood of achieving the 2 °C goal.

[1] Department of Geography, Simon Fraser University, Burnaby, BC, Canada. [2] Department of Geography, Planning and Environment, Concordia University, Montréal, QC, Canada. [3] Climate and Environment, St. Francis Xavier University, Antigonish, NS, Canada. ✉email: cnzotung@stfx.ca

Methane (CH_4) is a potent greenhouse gas, second only to CO_2 in the contribution to global temperature increase relative to pre-industrial levels[1]. Atmospheric CH_4 levels have grown rapidly since the year 2007[2,3]. The mean atmospheric CH_4 concentration ([CH_4]) currently exceeds 1900 parts per billion (ppb), which is >2.5 times larger than the pre-industrial average[4]. Recent trends of observed CH_4 levels are tracking future scenarios of unmitigated emissions[5,6]. For more than three decades, global CH_4 emissions have been dominated by anthropogenic sources mostly related to fossil fuel exploitation, livestock production, waste and agriculture[2,3,7]. Several studies have highlighted the importance of CH_4 mitigation for tackling climate change in the current century, in parallel with efforts to decarbonize the world economy[8–10].

A salient outcome of the 2015 Paris Agreement is the international commitment to keep global warming to well below 2 °C above pre-industrial levels, and pursue efforts to limit the mean global temperature increase to 1.5 °C above pre-industrial levels[11]. Achieving these temperate goals will require reaching net-zero CO_2 emissions alongside deep reductions in CH_4 and other non-CO_2 emissions by or around mid-century[12]. While the need for urgent CH_4 mitigation is now recognized (e.g. the Global Methane Pledge following COP26[13]), it is necessary to assess the importance of immediate versus delayed CH_4 mitigation to comply with the temperature goals in the Paris Agreement—particularly taking into account potential Earth system feedbacks. There is still limited knowledge about (i) the importance of biogeochemical feedbacks[14,15] in the context of CH_4 mitigation for achieving the Paris temperature goals[16,17], and (ii) long-term (i.e. multi-century) climate impacts of delaying or failing to mitigate CH_4 in the current century[18,19].

In this study, we use an Earth system model with an interactive CH_4 cycle to investigate the importance of immediate versus delayed CH_4 mitigation to comply with stringent warming limits in the Paris Agreement. It is important to note that: (i) currently, there are very few Earth system models driven by CH_4 emissions in their representation of the global CH_4 cycle[17,20]; and (ii) previous research applying an Earth system modeling approach to investigate CH_4 mitigation and its implication for meeting stringent temperature goals have relied on scenarios of prescribed [CH_4] without considering explicit changes in anthropogenic CH_4 emissions, potential climate-CH_4 feedbacks, and climate impacts of CH_4 mitigation beyond the 21st century[16]. We use version 2.10 of the University of Victoria Earth System Climate Model (UVic ESCM)[21], into which we implemented a simplified representation of the global CH_4 cycle—featuring simulated wetland CH_4 emissions (including CH_4 emissions from previously frozen soil carbon upon permafrost thaw)[22] and atmospheric CH_4 decay (See Methods). We validate the model against historical [CH_4] data and estimations of the global CH_4 budget in recent decades (See Supplementary Notes 1 & 2).

To assess the importance of timing for CH_4 mitigation to achieve the 2 °C temperature goal, we prescribe anthropogenic CH_4 emissions according to two Shared Socioeconomic Pathways (SSPs)[23,24]: (i) SSP1-2.6, a scenario featuring immediate CH_4 mitigation; and (ii) SSP3-7.0, a scenario without CH_4 mitigation throughout the 21st century. We design four additional scenarios of anthropogenic CH_4 emissions by assuming different initiation of CH_4 mitigation over the next few decades. These scenarios follow the SSP3-7.0 trajectory up to a specific year (2020, 2030, 2040 and 2050) and decline linearly to reach the same amount of CH_4 emissions as SSP1-2.6 in 2100, and then evolve according to the SSP1-2.6 extension beyond the 21st century (Fig. 1). These mitigation scenarios assume deep reductions in anthropogenic CH_4 emissions, corresponding to 69–78% of emission reductions between the year of peak emissions and the year 2100

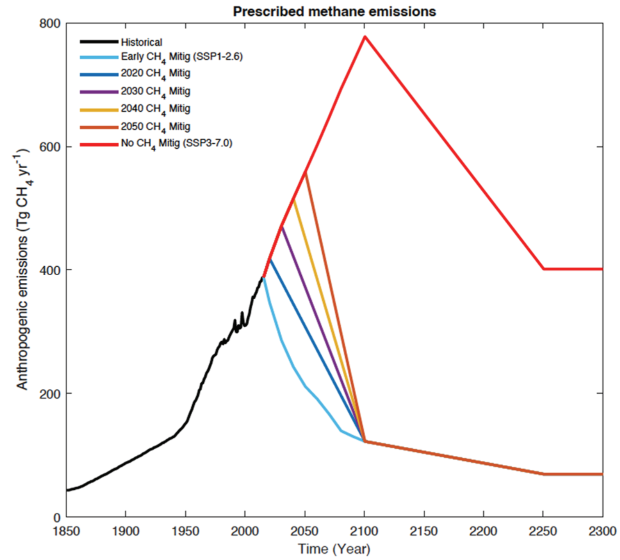

Fig. 1 Anthropogenic CH_4 emissions prescribed to the UVic ESCM in this study. Emissions in the early mitigation scenario ("Early Mitig") correspond to SSP1-2.6, whereas emissions without mitigation ("No Mitig") correspond to SSP3-7.0. Immediate and delayed mitigation scenarios follow the SSP3-7.0 CH_4 emission trajectory to the specified point in time and decline linearly to reach the same amount of CH_4 emissions as SSP1-2.6 in 2100, and evolve according to the SSP1-2.6 extension beyond the 21st century.

(Supplementary Table 1). CH_4 mitigation approaches that are currently achievable with existing strategies and technologies (i.e. technically feasible solutions) could– once deployed– lead to the elimination of >50% of global anthropogenic CH_4 emissions by the year 2050, with large contributions from cutting fossil fuel and solid waste emissions[25]. By design, our idealized mitigation scenarios allow us to compare the effect of immediate versus delayed CH_4 mitigation on the global climate at the end of the 21st century and beyond. We further assume that all other future anthropogenic forcings (including CO_2 emissions) evolve according to SSP1-2.6, which is a scenario aimed at limiting global warming to below 2 °C throughout the 21st century[26].

Results

Delaying CH_4 mitigation results in higher peak warming. The timing of CH_4 mitigation affects peak levels of [CH_4], [CO_2], and surface air temperature (SAT) in the future. According to our model, every 10-year delay in CH_4 mitigation increases the [CH_4] peak by 150-180 ppb (Fig. 2b). As such, delaying CH_4 mitigation to the 2040-2050 decade will increase the [CH_4] peak by 450–540 ppb relative to CH_4 mitigation initiated at or around 2020. The [CH_4] increase has a direct effect on global mean surface air temperature (SAT). For every 10-year delay in CH_4 mitigation, our model simulates an additional peak warming of ~0.1 °C (Fig. 2d). Delaying CH_4 mitigation to or around mid-century will increase the peak warming by 0.2–0.3 °C relative to a CH_4 mitigation initiated at present-day. Through feedback mechanisms operating in the Earth system (discussed below), one indirect effect of delaying CH_4 mitigation manifests with atmospheric CO_2 concentration ([CO_2]). Our model suggests that every 10-year delay in CH_4 mitigation implies an increase in the [CO_2] peak by 2-3 ppm (Fig. 2c). Consequently, delaying CH_4 mitigation to the 2040-2050 decade will increase the [CO_2] peak by 6-9 ppm relative to CH_4 mitigation at present-day. Relative to the early mitigation scenario (SSP1-2.6), delaying CH_4 mitigation to the 2040-2050 decade implies more [CH_4]

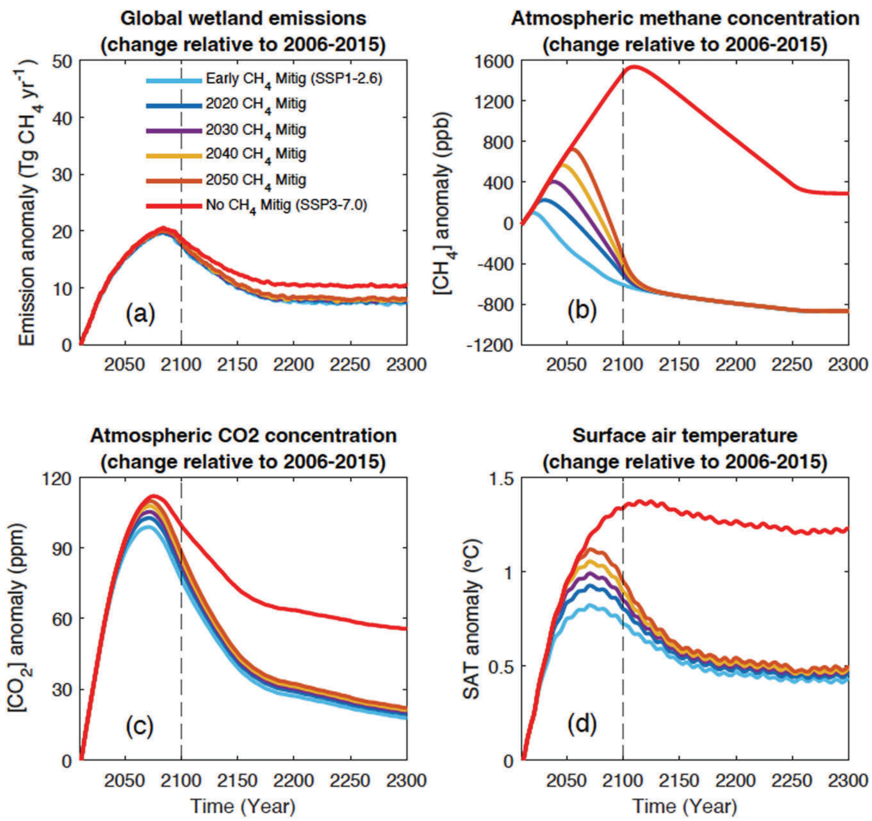

Fig. 2 Projected changes in atmospheric composition and temperature relative to present-day conditions under the mitigation scenarios explored in this study. Changes are shown for (**a**) global wetland CH_4 emissions, (**b**) atmospheric CH_4 concentration, (**c**) atmospheric CO_2 concentration, and (**d**) surface air temperature (SAT) relative to 2006-2015 for different initiation of CH_4 mitigation under the assumption that all non-CH_4 forcing agents (including CO_2) from anthropogenic sources evolve according to SSP1-2.6. The variability in the SAT curves is associated with the solar cycle.

(~200 ppb) and warming (~0.2 °C) at the year 2100 (Fig. 2b, d and Supplementary Note 3).

The decline in [CH_4] in response to CH_4 mitigation depends on the balance between CH_4 sources and sinks (Supplementary Fig. 1). CH_4 sources are dominated by anthropogenic CH_4 emissions (Fig. 1 and S1a), whereas CH_4 sinks in our model are proportional to the atmospheric CH_4 burden (Methods and Supplementary Fig. 1b, c). A delayed CH_4 mitigation results in a higher atmospheric CH_4 burden and [CH_4] than for an early mitigation, which implies a lag in the decline of CH_4 sinks and [CH_4] for the delayed mitigation in comparison to the early mitigation. Implications of this lag are most noticeable towards the end of the 21st century: while total CH_4 emissions converge in 2100 for all mitigation scenarios, the atmospheric CH_4 burden around the year 2100 remains high for delayed CH_4 mitigation relative to early CH_4 mitigation owing to a lag in CH_4 sinks (Supplementary Fig. 2). Overall, relative to the early CH_4 mitigation (SSP1-2.6), simulated CH_4 sinks in 2100 are ~65 Tg CH_4 yr^{-1} higher for CH_4 mitigation delayed to 2040-2050 (See Supplementary Note 4).

The peak warming is amplified by biogeochemical feedbacks. In our model simulations, SAT changes are influenced by biogeochemical feedbacks in addition to the timing of CH_4 mitigation. In particular, we find that the feedback of SAT changes on the atmospheric CO_2 concentration (referred to as the carbon-climate feedback) contributes to increasing peak SAT differences between early and delayed CH_4 mitigation. While we prescribe the same anthropogenic CO_2 emissions in all our model simulations (See Methods), atmospheric CO_2 levels are projected to be higher for delayed CH_4 mitigation scenarios than for early CH_4 mitigation scenarios (Fig. 2c). In comparison to early CH_4 mitigation, delayed CH_4 mitigation results in high [CH_4] levels that lead to high SAT levels. Enhanced global warming results in high [CO_2] levels, which in turn contribute to increase the SAT differences between early and delayed CH_4 mitigation scenarios. Such feedbacks between SAT and [CO_2] involve the response of natural CO_2 sinks to global warming and climate change. For instance, increased SAT enhances the release of CO_2 through soil respiration and weakens the uptake of atmospheric CO_2 by oceans through the solubility pump, resulting in enhanced [CO_2] and an amplification of global warming[14]. Overall, we deduce that the carbon-climate feedback amplifies the SAT response in late versus early CH_4 mitigation scenarios (Fig. 2d and Fig. 3). To quantify the contribution of the carbon-climate feedback to additional peak warming from delayed CH_4 mitigation, we performed additional model simulations with prescribed CO_2 concentration from the early mitigation scenario (i.e. Early CH_4 Mitig SSP1-2.6). These model simulations suppress the warming signal from delayed CH_4 mitigation that is due to the carbon-climate feedback, and their difference with our standard model simulations allows to quantify the magnitude of the feedback. According to our results, the contribution of the carbon-climate feedback to the peak warming increases for every 10-year delay in CH_4 mitigation (Fig. 3). The peak warming attributable to the feedback ranges from ~0.03 °C for CH_4 mitigation initiated in 2020 to ~0.06 °C for CH_4 mitigation initiated in 2050 (Fig. 3).

In contrast, we do not detect a strong feedback between global warming and wetland CH_4 emissions in our model simulations– despite changes in precipitation patterns and wetland areal extents between the different mitigation scenarios explored in this study (Supplementary Fig. 3). Differences in projected wetland CH_4

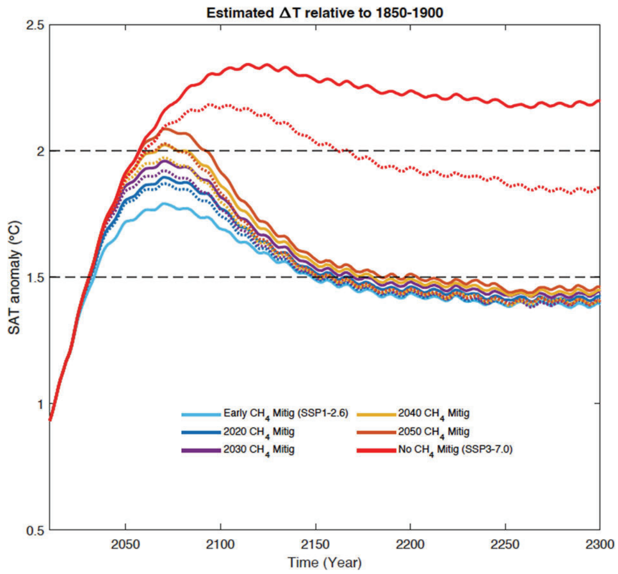

Fig. 3 Projected changes in air temperature relative to the pre-industrial era under the mitigation scenarios explored in this study. Changes are shown for global mean surface air temperature (SAT) relative to 1850–1900 for different initiation of CH_4 mitigation under the assumption that non-CH_4 forcing agents evolve according to SSP1-2.6. An estimate of 0.97 °C is considered for the global warming level in the 2006-2015 decade relative to the 1850–1900 period[29]. The variability in the SAT curves is associated with the solar cycle. Given that the observed historical warming level for the 2006-2015 decade relative to the 1850–1900 period is associated with an uncertainty of ±0.12 °C[29], we provide a version of this figure with the uncertainty range in the supplementary information (Supplementary Fig. 5). The dashed lines correspond to model simulations with prescribed CO_2 concentration from the Early CH_4 Mitig (SSP1-2.6) scenario, which imply climate projections without the carbon-climate feedback. The difference between dashed and continuous lines of the same color illustrates the magnitude of the carbon-climate feedback.

emissions between early and delayed CH_4 mitigation scenarios do not exceed 1 Tg CH_4 yr^{-1} for more than two centuries (Fig. 2a), which translates into a negligible fraction of [CH_4] and SAT differences between these mitigation scenarios. We conclude that the importance of the feedback between wetland CH_4 emissions and climate change is small under the low CO_2 emission scenarios explored in this study.

Timing of CH_4 mitigation and stringent warming limits. Determining the historical warming level is a critical aspect for assessing the implications of future climate projections on global warming limits in the Paris Agreement[27,28]. Our model simulates a global warming level of 1.1 °C for the 2006-2015 decade relative to the 1850–1900 period, whereas the recent Sixth Assessment Report (AR6) by the IPCC provides an estimate of 0.97 °C for the global warming level over the same decade relative to the same baseline period[29]. Hence, for this study, we adopt the above IPCC estimate to project future global warming levels associated with different scenarios of CH_4 mitigation (Fig. 3).

According to our model simulations, the 2 °C temperature goal can be achieved through rapid and deep cuts in anthropogenic CH_4 emissions along with stringent CO_2 mitigation. Our results suggest that global warming relative to the pre-industrial period (1850–1900) could be limited to well below 2 °C throughout the 21st century if global-scale CH_4 mitigation is initiated before 2030 while all other anthropogenic emissions evolve according to SSP1-2.6 (Fig. 3). However, if CH_4 mitigation is delayed to 2040, our results suggest that the 2 °C warming target will be overshot for at least two decades in the 21st century (Fig. 3), with longer mitigation delays implying longer overshoot periods of the 2 °C threshold. As expected with SSP1-2.6, all our considered CH_4 mitigation scenarios imply a breaching of the 1.5 °C limit relative to the 1850–1900 levels (Fig. 3).

Timing of CH_4 mitigation and its implications beyond the 21st century. The timing of CH_4 mitigation over the next three decades has implications beyond the 21st century. While anthropogenic CH_4 emissions prescribed to our model converge by the year 2100 for all considered scenarios other than SSP3-7.0 (Fig. 1), atmospheric [CH_4] levels for delayed and early CH_4 mitigation scenarios converge in the first half of the 22nd century (Fig. 2b). However, SAT differences between our mitigation scenarios persist for more than two centuries in the future (Fig. 2d), owing partly to the carbon-climate feedback (Fig. 2c and Fig. 3) as well as inertia in the climate system. These results suggest that, although CH_4 stays in the atmosphere for only about a decade, delaying CH_4 mitigation by 10–30 years will have an impact on global warming over many centuries.

The timing of CH_4 mitigation has long-term implications for achieving the temperature goals in the Paris Agreement. When implemented alongside CO_2 mitigation, rapid and deep reductions in CH_4 emissions will provide long-term benefits with regards to lowering global warming levels. According to our model simulations, initiating CH_4 mitigation before 2050 will increase the likelihood of limiting global warming to 1.5 °C in the long run—from the second half of the 22nd century onwards, after an overshoot in the first half of the 21st century (Fig. 3). However, even under the assumption of net-zero CO_2 emissions by mid-century, an eventual failure to mitigate CH_4 in the current century will raise global warming to >2 °C above pre-industrial levels throughout the 21st century and beyond (Fig. 3). We conclude that rapid CH_4 mitigation efforts will provide a long-term safeguard for the temperature goals in the Paris Agreement, whereas a failure to mitigate CH_4 within the next few decades will constitute a serious challenge for achieving the 2 °C warming limit.

Discussion

Previous studies have demonstrated that deep reductions in CH_4 emissions alongside stringent CO_2 mitigation by mid-century are needed to limit global warming to below 2 °C above pre-industrial levels, in agreement with our results[18,19,30,31]. Our study presents two additional findings: (i) the importance of biogeochemical feedbacks in the context of CH_4 mitigation to achieve stringent temperature limits, and (ii) long-term climate impacts of a delay or failure to mitigate CH_4 in the current century. Our study shows that the carbon-climate feedback amplifies the SAT response for delayed versus early CH_4 mitigation. In particular, our results suggest that the strength of the carbon-climate feedback increases for every 10-year delay in CH_4 mitigation (Fig. 3). The simulated contribution from the carbon-climate feedback to the peak warming ranges from ~0.03 °C to ~0.06 °C for CH_4 mitigation initiated in 2020 and 2050, respectively. Given that the UVic ESCM has a relatively high carbon-climate feedback parameter compared to most other ESMs[32] and a TCRE (transient climate response to cumulative emissions) value close to the CMIP6 ensemble mean[14,21], we infer that our estimated warming from the carbon-climate feedback lies in the upper 50-percentile of what the CMIP6 ESM ensemble would simulate in the context of this study. With regards to climate-CH_4 feedbacks, our model simulations suggest a negligible contribution from wetland CH_4 emissions to temperature change for every 10-year delay CH_4

mitigation in a low CO_2 emission scenario. However, we do not rule out the potential for a strong climate-CH_4 feedback involving wetlands, wildfires, and atmospheric CH_4 oxidation[15]—which would imply a potential underestimation of the contribution from the climate-CH_4 feedback to the additional peak warming under delayed CH_4 mitigation.

Despite that CH_4 stays in the atmosphere for only about 10 years, delaying CH_4 mitigation by 2-3 decades will have an impact on global warming over many centuries (Fig. 2d and Fig. 3). Such a delayed CH_4 mitigation may result in other long-term impacts such as a persistent sea-level rise over many centuries[33]. On the contrary, early CH_4 mitigation reduces the risk of losing the summer sea-ice across the Arctic Ocean[34]. A failure to mitigate CH_4 in the current century implies a high risk for global warming to exceed the 2 °C warming limit for more than two centuries even under net-zero CO_2 emissions by 2050 (Fig. 3). Such an overshoot of the 2 °C threshold has the potential to increase the risk for record-breaking climate extremes[35] and tipping elements in the Earth's climate system such as the dieback of the Amazon rainforest as well as the melting of the Greenland and West Antarctic Ice Sheets[36].

While mitigation research and efforts generally focus on achieving net-zero CO_2 emissions by 2050[12,19], it is becoming more clear that rapid reductions of both CO_2 and CH_4 emissions are crucial for holding global warming to well below 2 °C above pre-industrial levels[37]. To pave the way for CH_4 mitigation in the context of meeting the temperature goals in the Paris Agreement, there is a growing number of studies on: (i) understanding processes and reasons behind changes in [CH_4] trends in recent decades[2,5], (ii) constraining the global CH_4 budget[2,38], and (iii) developing strategies for reducing anthropogenic CH_4 emissions[39] as well as technologies for atmospheric CH_4 removal[40]. Research suggests that many anthropogenic sources of CH_4 can be reduced cost-efficiently[19,25,39,41], and that the priority for deep emission cuts should be in the energy, industry and transport sectors without neglecting the high potential from the waste and agricultural sectors[6,7,19,30,31,39]. If deployed rapidly, readily available measures for large-scale CH_4 mitigation by sector can contribute to slowdown global warming[18]. In addition to the Global Methane Pledge by >100 countries representing 70% of the global economy[13], multilateral partnerships already exist to support large-scale CH_4 mitigation (e.g. the Climate and Clean Air Coalition as well as the Global Methane Initiative[42–45]). Given that atmospheric CH_4 is a precursor to ground-level ozone (O_3)—an air pollutant with negative impacts on human health and crop yields, CH_4 mitigation offers the opportunity of simultaneously tackling climate change and improving air quality, global health, as well as food security[17,46,47].

Limitations of this study include uncertainties in the areal extent and dynamics of natural wetlands, as well as in the wide array of physical, biological, and chemical controls on CH_4 production and oxidation which determine the response of wetland CH_4 emissions to climate change[48]. Despite its simplicity, our wetland CH_4 model is capable of reproducing present-day wetland CH_4 emissions based on soil moisture, carbon, and temperature simulated by the UVic ESCM[22] (Supplementary Table 2). Additional limitations of this study are associated with: (i) static CH_4 emissions from non-wetland natural sources, and (ii) a constant lifetime for atmospheric CH_4 as part of the parameterization for atmospheric CH_4 decay. Natural CH_4 emissions from non-wetland sources (such as termites, lakes, wildfires, geologic seeps, marine hydrates) are not represented in the UVic ESCM and are held fixed in our model simulations (See Methods). Processes governing the future evolution of these natural CH_4 sources are poorly understood[2,49].

The consideration of a constant lifetime for atmospheric CH_4 is a simplified assumption made in this study as part of initial steps to represent the atmospheric CH_4 decay and the global CH_4 cycle in the UVic ESCM (See Methods and Supplementary Note 5). In reality, the atmospheric CH_4 lifetime varies by a few months to a few years mostly due to changes in atmospheric chemistry associated with CH_4 sinks[50], and this variation in the CH_4 lifetime has been invoked to explain past changes in the growth rates of atmospheric CH_4 levels[3,50]. Variations in the atmospheric CH_4 lifetime are mainly regulated by a chemical feedback involving the oxidation of CH_4 by the OH radical[3,50], a process not simulated by our model. This feedback mechanism is such that increasing [CH_4] (e.g. under delayed CH_4 mitigation) reduces the abundance of the OH radical, which further increases [CH_4] and raises the global warming level. Therefore, one consequence of our assumption of a constant lifetime for atmospheric CH_4 is a potential underestimation of the [CH_4] peak in delayed mitigation scenarios. However, our main result that delaying CH_4 mitigation increases the risk of breaching the 2 °C warming limit is not considerably affected by the use of different values for the atmospheric CH_4 lifetime in the range of published estimates (i.e. 7–11 years)[2] (Supplementary Fig. 4).

By design, this study makes a fundamental assumption with regards to future emission scenarios: effective mitigation of CO_2, other non-CH_4 greenhouse gases (GHGs), as well as aerosols, except for CH_4. This assumption is such that future emissions of non-CH_4 GHGs (including CO_2) and aerosols decline by mid-century according to a scenario consistent with limiting global warming to 2 °C by 2100 (i.e. SSP1-2.6), while anthropogenic CH_4 emissions continue to increase throughout the next three decades and beyond (i.e. SSP3-7.0). While we acknowledge the importance of aerosols and other non-CO_2 forcing agents in the context of climate mitigation to achieve the temperature goals in the Paris Agreement[16,51], our future scenarios focus on CH_4 mitigation to investigate recent concerns raised about sustained [CH_4] growth since 2007 and the associated potential challenge for achieving the 2 °C warming limit even under stringent CO_2 mitigation by mid-century[5,38].

Our study suggests that aggressive reductions of anthropogenic CO_2 emissions without CH_4 mitigation could push the Earth system beyond the 2 °C warming limit above pre-industrial levels for more than two centuries in the future. Initiating large-scale CH_4 mitigation in the current decade, along with stringent CO_2 mitigation, can allow to achieve the temperature goals in the Paris Agreement. However, delaying CH_4 mitigation to the next decade or beyond will increase the risk of breaching the 2 °C warming limit. According to our model simulations, every 10-year delay in CH_4 mitigation will result in an additional peak warming of about 0.1 °C. Consequences of such an increased peak warming over time and breaching the 2 °C warming limit are widespread, including an increased risk for an Arctic Ocean without sea ice in the summer[34], record-breaking climate extremes[35], the dieback of the Amazon rainforest[36], the disintegration of major ice sheets[36], persistent sea-level rise over multiple centuries[33], and several other global and regional impacts of increasing global warming levels on natural and socio-economic systems[52,53]. Considering that [CH_4] has been rising steadily since 2007 in line with unmitigated emission scenarios[5,6], we highlight the importance of immediate cuts in anthropogenic CH_4 emissions globally, along with stringent CO_2 mitigation, in order to increase the likelihood of keeping global warming to well below 2 °C above pre-industrial levels. Actions associated with the Global Methane Pledge[13] launched at COP26 in November 2021 should not be delayed, because every year of delayed CH_4 mitigation implies additional global warming.

Methods

Model description. We use the University of Victoria Earth System Climate (UVic ESCM) for our simulations. The UVic ESCM consists of a 2-D (vertically-integrated) energy-moisture balance model for the atmosphere coupled to a comprehensive 3-D ocean general circulation model (OGCM) with marine biogeochemistry, a thermodynamic sea ice model, and a land surface model with dynamic vegetation as well terrestrial carbon fluxes (in the form of CO_2)[54,55]. In this study, we use a version of the EMIC based on UVic ESCM 2.10[21] which features a multi-layer ground structure (i.e. 14 ground layers of unequal thicknesses extending down to a depth of 250 m) that is capable of simulating permafrost freeze-thaw processes as well as permafrost CO_2 fluxes (i.e. CO_2 release and uptake)[56]. Furthermore, the version of the UVic ESCM used in this study simulates the spatial and temporal dynamics of wetlands[57]. In particular, sub-grid scale wetlands are identified in the EMIC following a TOPMODEL approach for global models[58]. The areal extent of wetlands varies in response to changes in soil hydrology (soil moisture content, runoff, surface inundation, etc.), which is affected by changes in precipitation, evapo-transpiration, temperature, vegetation—among many other atmospheric and terrestrial processes. In this study, we use a modified version of UVic ESCM 2.10 into which we incorporated a simplified representation of the global CH_4 cycle (See next sections).

Wetland CH_4 emissions. Wetland CH_4 emissions are simulated in the UVic ESCM following a recent model development[22]. Wetland CH_4 emissions are calculated as the balance between microbial production and oxidation of CH_4 in the soil column. CH_4 production is calculated in each soil layer as a function of moisture content, carbon content, temperature, and the relative depth from the soil surface. In this approach, soil moisture (i.e. water saturation) represents potential anoxic conditions. Soil carbon represents organic matter that may be accessed by methanogens. Soil temperature allows to estimate potential changes in methanogenic activity, whereas the relative depth from the soil surface allows to represent the net effect of depth-dependent controls on CH_4 production that are unresolved by the UVic ESCM (e.g. the quality of organic matter and the distribution of methanogens in the soil). CH_4 production is assumed to not take place in dry soil layers (i.e soil layers unsaturated with water) as well as in frozen soil layers. CH_4 oxidation is calculated for the entire soil column as a fraction of the amount of CH_4 produced in the soil column. The oxidized CH_4 fraction is determined based on an estimated oxic zone depth, which represents the prevalence of methanotrophs in the soil. This fraction increases as the oxic zone deepens. By design, our model simulates wetland CH_4 emissions associated with CH_4 production across the globe (including CH_4 emissions from previously frozen soil carbon upon permafrost thaw)[22].

Atmospheric CH_4 and associated radiative forcing. A simple one-box model is used to simulate the evolution of the atmospheric CH_4 burden (B) with time as the balance between total CH_4 emissions (E) and total CH_4 sinks (S). The box model is defined as $\frac{dB}{dt} = (E - S)$, where $E = E_a + E_w + E_n$ represents the sum of prescribed anthropogenic CH_4 emissions (E_a), simulated wetland CH_4 emissions (E_w), as well as natural CH_4 emissions from non-wetland sources (E_n) such as termites, wild ruminants, wildfires, lakes, rivers, geologic seeps, and marine hydrates. Given that the UVic ESCM does not incorporate these non-wetland natural sources and in the absence of dataset for CH_4 emissions from these sources, we assume that non-wetland natural CH_4 emissions remain constant in time at 45 Tg C yr^{-1} (equivalent to 60 Tg CH_4 yr^{-1}). This value is in the range of estimated total CH_4 emissions from non-wetland natural sources over the last four decades[2,3] as well as pre-industrial periods[59]. Sinks of atmospheric CH_4 are aggregated into a single term (S) calculated as $S = B\,(1 - \exp(-\frac{1}{\tau_{CH4}}))$, where τ_{CH4} is the atmospheric CH_4 lifetime assumed to be 9.3 years[2]. Similar estimates for the atmospheric CH_4 lifetime have been reported for the pre-industrial era (9.5 ± 1.3 years) and present-day (9.1 ± 0.9 years)[60]. At each time step, $[CH_4]$ is determined based on the atmospheric CH_4 burden (B) by using a factor equivalent to ~2.8 Tg CH_4/ppb. Radiative forcing associated with changes in $[CH_4]$ is calculated using the formulation in ref. [61] and is accounted separately from the aggregated forcing of other non-CO_2 GHGs that is prescribed to the UVic ESCM in its standard configuration[21].

Non-CH_4 radiative forcing agents. To drive the UVic ESCM over the 1850–2300 period (1850–2014 for the historical simulation and 2015-2300 for future projections), we use CMIP6 data for non-CH_4 natural and anthropogenic radiative forcing agents[23,62–64]. For natural forcing agents (volcanic and solar), we use volcanic radiative forcing anomalies spanning the historical period (1850–2014)[64] and solar constant data prescribed to 2300[63]. For anthropogenic forcing agents, we (i) use CMIP6 data for the historical simulation, and (ii) assume that all non-CH_4 GHGs (including CO_2) as well as aerosols evolve according to a scenario consistent with limiting global warming to 2 °C throughout the future (i.e. SSP1-2.6). Specifically, we prescribe CO_2 emissions from fossil fuels as defined in the SSP1-2.6 scenario and their long-term extension[23,24]. The SSP1-2.6 scenario features strong reductions in CO_2 emissions as well as negative CO_2 emissions (i.e. artificial removal of atmospheric CO_2) in the second half of the 21st century[65]. Furthermore, we prescribe gridded land-use change (LUC) data according to SSP1-2.6[66] and the UVic ESCM internally calculates corresponding LUC CO_2 emissions. The radiative forcing of CO_2 is calculated within the UVic ESCM following the formulation from ref. [61]. Radiative forcing values of other non-CH_4 GHGs are calculated externally using concentration data and their extension[23], which are then summed up into an aggregated forcing that is prescribed to the UVic ESCM. For anthropogenic sulfate aerosols, we prescribe SSP1-2.6 gridded aerosol optical depth (AOD) data to the UVic ESCM[67,68] and the model uses this data to internally calculate the associated radiative forcing. While forcing data for CO_2 and other non-CH_4 GHGs extend to 2300[23], forcing data for LUC and sulfate aerosols are prescribed to 2100 and their radiative forcing are held fixed at their 2100 values in our climate simulations.

Reporting summary. Further information on research design is available in the Nature Portfolio Reporting Summary linked to this article.

Data availability

The model outputs analyzed in this study are archived at https://doi.org/10.20383/102.0748[69].

Code availability

The code for the University of Victoria Earth System Climate Model (UVic ESCM) used in this study is available at https://doi.org/10.5281/zenodo.7999745[70].

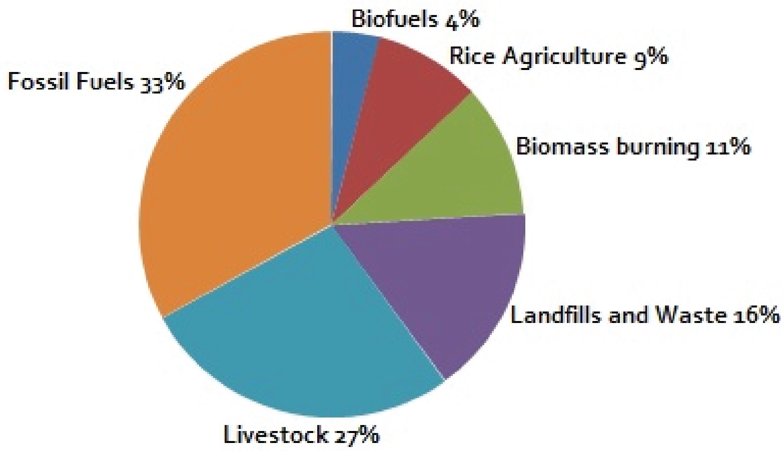
The Challenge

Methane is a powerful greenhouses gas with a 100-year global warming potential 28-34 times that of CO2. Measured over a 20-year period, that ratio grows to 84-86 times.

About 60% of global methane emissions are due to human activities. The main sources of anthropogenic methane emissions are the oil and gas industries, agriculture (including fermentation, manure management, and rice cultivation), landfills, wastewater treatment, and emissions from coal mines. Fossil fuel production, distribution and use are estimated to emit 110 million tonnes of methane annually.



Methane is the primary component of natural gas, with some emitted to the atmosphere during its production, processing, storage, transmission, distribution, and use. It is estimated that around 3% of total worldwide natural gas production is lost annually to venting, leakage, and flaring, resulting in substantial economic and environmental costs.

Coal is another important source of methane emissions (/node/33). Coal mining related activities (extraction, crushing, distribution, etc.) release some of the methane trapped around and within the rock. Methane is emitted from active underground and surface mines as well as from abandoned mines and undeveloped coal seams.

The geological formation of oil can also create large methane deposits that get released during drilling and extraction. The production, refinement, transportation and storage of oil are all sources of methane emissions, as is incomplete combustion of fossil fuels. No combustion process is perfectly efficient, so when fossil fuels are used to generate electricity, heat, or power vehicles these all contribute as sources of methane emissions.

On a global scale, methane emissions from oil and natural gas systems account for 1,680 MtCO2e. The estimates are considered to be uncertain and are thought to be low.

Based on the best currently available data, around 3.6 trillion cubic feet (Tcf) (or 102 billion cubic meters (bcm)) of natural gas escaped into the atmosphere in 2012 from global oil and gas operations. This wasted gas translates into roughly U.S. $30 billion of lost revenue at average 2012 delivered prices, and representes about 3% of global natural gas production.

Emissions are expected to grow under a central growth scenario by 23% between 2012 and 2030.

Regarding the global reduction potential by 2030, it is estimated that emissions could be reduced by 26% using existing technology (equal to 1,219 MtCO2e).

Despite methane's short residence time, the fact that it has a much higher warming potential than CO2 and that its atmospheric volumes are continuously replenished make effective methane management a potentially important element in countries' climate change mitigation strategies. As of today, however, there is neither a common technological approach to monitoring and recording methane emissions, nor a standard method for reporting them.

WESTERN**UNITED**DAIRIES

February 20, 2024

The Honorable Steven S. Cliff
Executive Officer
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Regarding: **Proposed Amendments to the LCFS Program**

Dear Mr. Cliff:

Western United Dairies is the largest dairy farmer trade organization in California representing dairy farms from throughout the state of all sizes. Our members are committed to meeting the goals of SB 1383 and reducing livestock manure methane emissions. As a result of that commitment, many of our members have installed anaerobic digesters to capture manure methane emissions and produce Renewable Natural Gas (RNG), which displaces fossil fuels. In both capturing fugitive methane and displacing fossil fuels these projects significantly reduce greenhouse gas (GHG) emissions. Likewise, these projects also improve air quality by helping to transition away from diesel fueled vehicles to cleaner RNG.

259.1 WUD urges the Air Board to continue to provide credits for avoided methane emissions from livestock manure, which are the most cost effective GHG emissions reductions funded by the State. When asked by the State, dairy farmers stood up and achieved what was asked of them, it is important that the State now uphold its support of these projects through the LCFS program as promised. Therefore, dairy biogas producers should receive full credit for avoided methane emissions from livestock manure that is used to produce biofuels participating in the LCFS program.

The success of the LCFS program cannot be overstated in bringing down the carbon intensity of transportation fuels, which is one of the more difficult sectors to decarbonize. By linking the carbon intensity of fuels to voluntary projects like digesters on dairy farms, the program has also spurred a significant reduction in methane emissions. This has driven change and innovation on farms to be part of the solution. It is important that ARB maintain the course that has gotten us here and not abandon those that have stepped up to be part of the solution. To accomplish this the value of the avoided methane emissions must continue to be included in the carbon intensity score of fuels produced from dairy biomethane. The projects developed by our members to help ARB achieve its goals are not inexpensive to operate and maintain. The LCFS is the most important revenue source for these projects and keeps these projects viable. It also continues to

WESTERN**UNITED**DAIRIES

reward innovation and maintains the pace of emissions reductions, which has been unprecedented.

California dairy farms are very sensitive to leakage with the California dairy herd continuing to migrate to other states as shown in recent ARB reports on dairy and livestock populations, including the ARB GHG inventory. Removing the avoided methane emissions value from the LCFS will add pressure on California dairies to leave California to other states without GHG reductions targets for dairies. This will increase global GHG emissions counter to ARB goals. The most effective way to achieve ARB's GHG goals is to support California's dairy farmers in their reduction of methane emissions thereby providing an example to other states and countries on how to achieve emissions reductions and maintain a healthy farm sector that provides jobs in much needed areas of the state and supports fresh local food production. This is how California can achieve meaningful global GHG emissions reductions by being a successful laboratory of innovation while at the same time supporting our economy.

Consolidation is not unique to California dairies. Many businesses in California have experienced consolidation to survive increasing costs and regulatory pressures, including environmental pressures. Consolidation has been happening in dairies across the United States for over 50 years, and California is no exception. The LCFS program is not driving this, but other business pressures to become more efficient and productive. Scale allows dairies to implement practices that reduce GHG emissions and improve air quality. California dairies also provide important year-round jobs, many to disadvantaged communities, that would disappear without our dairy farms.

Ending credits for avoided methane emissions would be counter to SB 1383. It also sends a message that investments in these projects are risky as the state is not willing to support these projects long term. These projects provide some of the most cost-effective investments the state is making in carbon reductions and should be strengthened, not abandoned. For all these reasons, WUD urges ARB to maintain a lifecycle analysis approach to carbon emissions, including avoided methane emissions. Western United Dairies (WUD) appreciates the opportunity to provide comments regarding the proposed amendments to the Low Carbon Fuel Standard (LCFS).

Sincerely,

Paul Sousa

Paul Sousa, Director of Regulatory and Environmental Affairs

Subject	Low Carbon Fuel Standard

Comment

As President of Castle & Cooke Aviation Services, Inc. headquartered at the Van Nuys Airport in Los Angeles, with 36
260.1 employees in Southern California, I am opposed to the CARB proposal to eliminate the LCFS's current exemption of jet fuel due to the following concerns:

1. The new amendment would increase the current price of jet fuel, negatively impacting the aviation industry's economic impact.

2. Jet fuel was originally recognized by CARB as exempted. This change would increase company demerits if jet fuel were used, negatively impacting overall company goals.

3. SAF production does not match current fuel uptake rates, and this proposal would do nothing to increase SAF availability.

4. Reduction in aviation activity due to the above items could negatively impact my employment numbers reducing payroll and tax contribution to the state.

We appreciate the CARB's consideration of my comments and concerns and look forward to moving ahead to find plausible, economically viable, and mutually beneficial solutions to sustainable aviation through the state.

Comment 270 for Proposed Low Carbon Fuel Standard Amendments (lcfs2024) - 45 Day.

First Name	John
Last Name	Peck
Email Address	familyfarmdefenders@yahoo.com
Affiliation	Family Farm Defenders
Subject	LCFS methane offsetting through biogas digesters needs to stop

Comment

Dear Governor Newsom and California Air Resources Board (CARB) members,

On behalf of Family Farm Defenders, a national grassroots organization based in Madison, WI with over 3000 members in all fifty states, including CA, I am writing to you to express our concern about CAFO biogas digesters being used to offset pollution generated in your state through the Low Carbon Fuel Standard (LCFS)

Pollution trading is fundamentally flawed in that it does not actually require pollution reduction, but allows polluters to instead shift their pollution impact to other communities. Worse
261.1 yet, many of these supposed offsets have been shown to be bogus, meaning that the over all climate change pollution impact is actually worse.

This is certainly true in the case of CAFO biogas digesters, supposedly offsetting carbon dioxide emissions by reducing methane emissions, but in reality many of these biogas digesters are doing neither. In the case of WI there are over a dozen CAFO mega dairy farms who have long been claiming methane offset credits under the LCFS carbon market trading scheme. Thanks to the diligent oversight of many local citizen activists, we know that many of these WI CAFO biogas digesters are not actually functional as claimed and that methane is not being actually being reduced.

When this corruption was exposed in the media, CA authorities had to work hard to claw back the bogus offset credits from the WI CA biogas digesters, but that should not be the belated response if there was proper vetting and accountability mechanisms in place. Concerned private citizens should not have to be the watchdog for taxpayer-subsidized government-created carbon/methane trading offset markets. To be honest, such false offset claims in a pollution trading market is tantamount to wire fraud and should lead to federal prosecution.

Many of the mega dairy WI CAFO biogas digesters implicated in this fraud have a long sordid record of breaking other state and federa laws, including violations of labor laws (some farmworkers have died at these facilities trying to work on the biogas digesters) a

well as numerous environmental regulations related to the Clean
Water and Clean Air Acts. Some of our WI CAFO biogas digesters
have even blown up and been implicated in massive manure leaks
contaminating public water supplies, raising potential liability
concerns for anyone who may be financially connected - such as
those engaged in the CA LCFS carbon trading market.

As a national family farm organization, we would urge you to no
longer allow methane offsets in the LCFS market - these are dubiou
(at best) and the mega dairy CAFOs claiming such credits are
causing serious harm to Midwest rural communities. At minimum,
there should be no "grace period" allowed for such CAFO biogas
offset claims - their lousy track record hardly warrants such. Th
261.2 "life cycle" analysis of supposed methane emissions as a possible
offset for carbon dioxide emission needs to be seriously
reevaluated - especially if the credit claims are egregiously
overstated or even totally bogus.

The best offset would be giving LCFS credits to rotational grazin
dairy operations (which are actually the most economically viable
and climate friendly here in the Midwest according to many studie
from the UW-Madison Center for Dairy Profitability), but that is
261.3 sadly not acceptable under the current LCFS carbon trading system
Apparently, if a family farmer does NOT create a methane problem i
the first place (by not confining their animals in a building and
then putting their manure into anaerobic lagoons) then they can n
get any taxpayer subsidized carbon credit for solving the climate
crisis.

If the State of California is serious about reducing GHG emission
through a pollution trading system, then they should not allow
corrupt CAFO operators across the country to take advantage of
261.1 cont. shoddy oversight and lackadaisical accountability to bilk taxpaye
through bogus offsets.   We ask that you no longer shift your
pollution responsibility onto Midwest rural communities (or
anywhere else for that matter) and terminate the methane biogas
digester offsets in the LCFS program.

Board Comments Home

February 20, 2024

Ms. Liane Randolph
Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95864

Re: CARB Proposed Low Carbon Fuel Standard Amendments

In response to California Air Resources Board (CARB)'s proposed updates to the Low Carbon Fuel Standard (LCFS) [1], Japan Hydrogen Forum (JH2F) is pleased to submit the following comments for consideration. JH2F is an organization formed in 2021 to contribute to the goal of decarbonization in the United States, consisting of 31 Japan-affiliated companies with hydrogen related technologies from production, carrier conversion, transportation, storage to utilization, including hydrogen fuel cell providers for heavy-duty (HD) truck and cargo handling equipment OEMs and retail hydrogen refueling station (HRS) providers in California. We would like to express our sincere gratitude for your staff's work on the development of the proposed rule and their commitment to improving the LCFS to achieve carbon neutrality by 2045 and reduce greenhouse gas emissions 85% below 1990 levels by 2045.

While acknowledging the continued improvements to the program, we would propose some critical refinements to ensure the success of hydrogen, and its necessary role in meeting California's 2045 carbon neutrality goal.

Increasing CI Targets and Market Stability

263.1 We strongly support staff's recommendation of the 30% reduction in fuel carbon intensity (CI) by 2030
and a 90% reduction in fuel CI by 2045 from a 2010 baseline. However, we are concerned that the
historically low credit prices [2] will continue through 2025, which has a chilling effect on providers'
263.2 financing further stations and is increasingly discouraging OEMs from committing capital to Hydrogen
fuel cell light-duty (LD) and HD vehicles. Unlimited biodiesel and renewable diesel supply has been one
of the leading causes of the LCFS credit market's inability to effectively support other pathways.

We therefore urge starting with tighter targets and policies that can result in the immediate recovery of credit prices. We request the Board implement the one-time 5% CI step down and the auto acceleration mechanism (AAM) sooner than the proposed date.

777 S. Figueroa St., Suite 3750 | Los Angeles, CA 90017 | Japan Hydrogen Forum (JH2F) | USA - JETRO

Infrastructure Crediting

Crediting Period

263.3 The shift from a 15-year to a 10-year timeframe for HRI crediting has a significant impact on station financing and economics. Notably, this change introduces a new challenge for HD stations, which are both larger and more capital-intensive. The shorter 10-year timeframe contrasts with the previously longer capacity crediting period, creating a misalignment with the capital costs associated with hydrogen station infrastructure. Reevaluating the timeframe in consideration of the unique characteristics and financial requirements of hydrogen station infrastructure is crucial for fostering a conducive environment for hydrogen development in this sector.

LD HRI program

263.4 In addition to the crediting period of 10-year timeframe, limiting capacity to 600 kg/d, hinders the growth of the HRS network. This is especially true for the 600 kg/d capacity cap given that medium-duty (MD) trucks typically fill at neighborhood fueling stations, not HD stations along freeways (i.e., truck stops). We urge the Board to simply extend the LD HRI program "as is" and revisit in a few years to ensure the program is operating as intended and serving disadvantaged communities.

Inequity in Capacity Crediting Standards

263.5 We agree that renewable hydrogen production is the ultimate pathway for transportation, however, the imposition of an 80% renewable content requirement exclusively for HRI may be premature and overly restrictive, particularly in comparison to Fast-Charging Infrastructure (FCI). This requirement places hydrogen at a competitive disadvantage against other energy sources, which benefit from substantial federal, state, and ratepayer subsidies not extended to hydrogen, and could significantly increase relative costs. We believe that the exclusive application of this requirement to hydrogen tilts the scale heavily against fuel cell pathways. We suggest that this additional requirement should be eliminated as it is unnecessary and counter to the carbon intensity focus and technology neutral principles that have driven innovation and investment in the LCFS program to date.

We appreciate your consideration and thoughtful feedback to address our concerns. We look forward to contributing to California's goal of zero-emissions transportation.

Sincerely,

Takehito Yokoo
Chairperson,
Japan Hydrogen Forum

RE: Notice of Public Hearing to Consider Proposed 2024 Low Carbon Fuel Standard Amendments (LCFS)

Dear Chair Randolph and Honorable Board Members:

Fermata Energy is pleased to provide comments in response to the Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments.[1] In June 2023, Fermata Energy staff members had the opportunity to meet CARB representatives Joshua Cunningham, Analisa Bevan, and Leslie Goodbody at the California-UK Vehicle-to-Everything ("V2X") Global Expert Mission. The discussion in this meeting included the proposal to extend the LCFS program scope to value V2X benefits, which was supported by Fermata Energy, ev.energy, and others. Our first three proposals are not addressed in the proposed LCFS Amendments, and as such, we raise new issues for CARB's consideration. Our fourth recommendation supports the revisions to Section 5.b of the "Proposed Regulation Order: *Proposed Amendments to the Low Carbon Fuel Standard Regulation*," on the use of LCFS Holdback Funds for V2X Programs.[2]

Background: Founded in 2010, Fermata Energy is a leading Vehicle-to-Everything ("V2X") bidirectional charging services provider. Fermata Energy designs, supplies, and operates the technologies required to integrate electric vehicles ("EVs") into homes, buildings, and the electric grid. Fermata Energy's V2X platform incorporates CHAdeMO and CCS connectors in a

[1] See California Air Resources Board Notice Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments available at https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_notice.pdf,

[2] See Section § 95483. Fuel Reporting Entities. < (c) For Electricity Used as a Transportation Fuel. (1) Residential EV Charging. (A) Base Credits. < 5b, at page 45,https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_appa1.pdf

bidirectional charger and management software platform that connects the EV and electricity user to the grid. Fermata Energy's V2X platform extends the value of an EV and allows the vehicle to act as a dispatchable energy storage resource when the vehicle is not in use.

Fermata Energy's customers today are earning thousands of dollars per EV and EVSE pair through Vehicle-to-Grid ("V2G") and Vehicle-to-Building ("V2B") programs nationwide. The company's bidirectional EV charging system is the first to be certified by UL Solutions in North America to UL 9741, the Standard for Bidirectional EV Charging System Equipment and is the first to earn approval in the U.S. from a major OEM for battery warranty.

In addition to developing the hardware and software required to perform V2X activities, Fermata Energy has spent over 10 years studying how V2X can unlock additional value streams from EVs, including those that are commercially viable today without regulatory intervention and how to best monetize these value streams. Fermata Energy has extensive experience with analyzing use cases, monetization mechanisms, and business models to maximize the benefits of V2X technologies. Vehicle Grid integration ("VGI") encompasses both V1G (smart and managed charging solutions) and V2X (bidirectional power transfer to the grid, building, home, microgrid, or any other external load source). While V1G enables EVs to participate in off-peak charging programs and provide automated load management, V2X unlocks additional value streams and benefits for ratepayers and the grid by enabling the discharge of power stored onboard an EV. V2X that Fermata Energy provides unlocks the value of EVs to provide all of the services that that V1G does, in addition to backup power/resilience, demand charge management, demand response, system-wide peak shaving, and ancillary services, among others.

The interest in V2X commercialization is widespread and accelerating. In addition to the launch of the Ford Lightning (EV F150 pickup truck) V2H offering, 2023 saw several EV manufacturers announce plans to make their EVs bidirectional.[3] Furthermore, several electric vehicle supply equipment ("EVSE") manufacturers announced plans to bring bidirectional chargers to market, expanding the limited number of bidirectional chargers that are available today.[4] The ACC II amendments are timely and offer an opportunity for CARB to ensure that manufacturers' bidirectional EVs meet basic interoperability standards for bidirectional charging and demonstrate these capabilities through assurance testing.

Fermata Energy Recommendations

1. **Proposed Methodology for Accounting for Energy for Transportation for V2X Customers:** We would like to propose the following formula to account for energy for
264.1 transportation for V2X customers that wish to generate LCFS credits. Electricity dispensed from electric vehicle supply equipment ("EVSE") for transportation can be netted out from the overall electricity dispensed for a V2X system that includes a bidirectional charger that has an approved interconnection agreement with the electric distribution company ("EDC") according to the following:

Electricity charged for driving (kWh) = Total electricity charged (kWh) - Electricity discharged (kWh)

Note: Where charged and discharged electricity are the energy flows measured at the charger meter.

$$Electricity\ charged\ for\ driving\ (kWh)\ =\ [Total\ electricity\ charged\ (kWh)\ -\ Electricity\ discharged(kWh)]$$

The two energy uses of a V2X charger are 1) driving (transportation) and 2) exports to buildings or the grid, so the total energy charged at any charger will be equal to the energy required to refill the battery for those uses. This means that for V2X services, energy discharged (kWh) = energy charged (kWh). The remainder of charging at a V2X charger is to refill from driving uses. We understand and appreciate that this proposed methodology above can be adopted with a technical note (e.g., Guidance Document or similar) and therefore does not require an amendment to the LCFS program amendment. However, we take this opportunity to share our above proposed methodology to be included in the public record as CARB considers LCFS program amendments and would prefer the greater certainty that a regulatory amendment provides.

2. **Consideration for Account for V2X Discharge in LCFS Methodology**

The stated aims of the LCFS program are: "[...] to decrease the carbon intensity of California's transportation fuel pool and provide an increasing range of low-carbon and
264.2 renewable alternatives, which reduce petroleum dependency and achieve air quality benefits."[5]
Fermata Energy understands the scope and purpose of the program, and that LCFS is a fuels regulation aimed at decarbonizing the transportation sector. However, below, we expand upon how accounting for V2X discharge in the LCFS methodology will help CARB achieve the stated

[5] https://ww2.arb.ca.gov/our-work/programs/low-carbon-fuel-standard/about#:~:text=The%20LCFS%20is%20designed%20to,and%20achieve%20air%20quality%20benefits

goals of the LCFS program and further its mission.[6] CARB may have to expand the scope of LCFS to fully incentivize the potential of bidirectionally-enabled EVs to support transportation decarbonization and provide the associated air quality benefits.

Decreasing the Carbon Intensity of CA's Transportation Fuel Pool

Bidirectionally-enabled EVs decrease the carbon intensity of California's transportation fuel pool in the same way as other EVs: by displacing the emissions from mobility (driving) from a conventional fuel to an alternative fuel (electricity). This is included in the methodology proposed in (1) above. The formula is attractively simple, however it does not take into account the potential benefits of V2X for further lowering CO2 from transportation assets.

V2X Discharge Enables EVs to Generate Revenue for Grid Services, Lowering EV TCO, and Helping Accelerate EV Adoption and Renewables Integration in CA

EVs are the primary mechanism to achieve transportation decarbonization. V2X accelerates the transition to electric vehicles, by providing new value streams that increase
264.2 consumer adoption of EVs by lowering EV total cost of ownership (TCO). This also increases the range of consumer options in selecting an EV, which is aligned with the goals of the LCFS program.

In addition to lower EV TCO, V2X supports renewables integration. By fully unlocking the ability of EVs to respond as grid-supporting, flexible load resources, V2X can help California achieve a cleaner generation profile. Bidirectional EVs can discharge to the grid during the CA system-wide peak and be aggregated into Virtual Power Plants (VPPs) to displace fossil-fuel powered peaker plants. Bidirectional charging can also charge when there is excess solar and wind power generation, thereby reducing renewable energy curtailment.

Achieving further air quality benefits from the transportation sector, beyond the transportation sector, by reducing both grid and transportation emissions

What an EV does when it is parked is just as important as what an EV does when it is driving. Recognizing V2X in LCFS can turn transportation assets into carbon sinks; bidirectional charging, when optimized for carbon-signals, can lead to a net displacement of CO2 emissions. By following a carbon signal and discharging at high Carbon Intensity (CI) times and charging at low CI times, V2X EVs create a net environmental benefit, turning EVs into potential carbon sinks. The LCFS market design may need to change to create the incentives for EVs to provide these additional environmental benefits. While this may necessitate an expansion of LCFS's

[6] "CARB's mission is to promote and protect public health, welfare, and ecological resources through effective reduction of air pollutants while recognizing and considering effects on the economy. CARB is the lead agency for climate change programs and oversees all air pollution control efforts in California to attain and maintain health-based air quality standards." https://ww2.arb.ca.gov/about

official scope, these goals do align with CARB's broader mission as an organization and the spirit of the LCFS program.

Proposed formula for CARB to include V2X discharged energy in LCFS accounting

Fermata Energy proposes that CARB make the total energy cycled through the vehicle battery in the course of V2X operations eligible for LCFS credits. The formula would account for the hourly energy charge and discharge flows and the associated hourly carbon emissions, which could lead to either adding or subtracting LCFS credits from a participants' credits earned depending on performance.

The proposed formula for V2X is then:

$$\sum_{h=0}^{h=H} Net\ Electricity(h) \times CI(h) = [Electricity\ charged(h) - Electricity\ discharged(h)] \times CI(h)]$$

Where H is the total number of hours in the year, h is the hour, Electricity charged and Electricity discharged are the hourly energy measurements at the charger, and CI is the carbon intensity recorded for hour h.

Worked example of V2X as net carbon sink

Here, we propose the example use case of a delivery truck at a warehouse with V2G charging infrastructure on-site. This medium-heavy duty vehicle has a usable battery capacity of 120 kWh, and is parked at its designated parking space and charger. At 7 am, as instructed by Fermata Energy's algorithms, the truck starts discharging electricity for 2 hours until 9 am,
264.2 discharging a total of 40 kWh of electricity. During this time, the carbon intensity of the CA grid is 450 gCO2/kWh on average. Fermata Energy's V2X software ensures that the vehicle is left with enough state of charge to complete its morning duty cycle. At 9 am, the vehicle leaves the warehouse and drives 50 miles, for which it uses 15 kWh of electricity. When the vehicle returns to the warehouse, Fermata Energy charges it from about mid-day to 2:30 pm, recharging 15 + 40 kWh = 55 kWh, when the CI of the grid is 0 gCO2/kWh. This creates a carbon footprint for the vehicle of (55 x 0) - (40 x 450) = -18,000 gCO2/kWh, i.e. a net CO2 reduction of 18 kg.

Conclusion on including V2X discharge

In summary, supporting V2X EVs are still primarily transportation assets that are purchased for mobility as a primary use; but their full potential should be addressed via the LCFS program. CARB has an opportunity to incentivize EVs to generate far greater emissions reductions by making V2X eligible for carbon credits in the LCFS program. Standard EV charging, in comparison, can only minimize emissions from mobility, i.e. offset its own carbon footprint. V2X EVs can generate far greater emissions reductions, beyond the vehicle use itself by enabling discharge to the grid during peak CI times. Fermata Energy recommends that the program fully incentivize these benefits for the state at large by making all V2X discharged and charged energy accountable for LCFS credits. This change would help achieve the program's goal of lowering emissions in the state.

264.3 **3. Consideration of WattTime Data for More Accurate Carbon Intensities (CI) Values**

Fermata Energy recommends that CARB consider using WattTime Data or a similar provider for LCFS CI values. More accurate, granular data on marginal carbon intensities of charging from grid electricity in California is widely available today, from data providers such as WattTime or electricitymaps.

WattTime provides average and marginal operating emissions rates (AOER and MOER) for California grid areas, at 5-min intervals. WattTime data is used in the Self-Generation Incentive Program (SGIO), which is another CA program that aims to reduce carbon emissions from subsidized assets (battery energy storage systems), for which the data is made available to registered users for free (via CEC's MIDAS open access portal).

Fermata Energy has assessed the difference in the CI assumptions required by the LCFS program vs. the marginal operating emissions rates (MOER) calculated by WattTime. We have compared the two data sets and their impact on emissions calculations for two representative vehicle profiles: a residential and a fleet use case over a year. We found that the LCFS CI assumptions significantly underestimate the emissions relative to using the WattTime MOER (see Appendix Table on page 8). This means that EV market participants optimizing against the LCFS CIs are not achieving as many emissions reductions as they could, even for standard charging technologies.

While Fermata Energy cannot comment on the differences in these underlying models, the extent of the difference between the two data sources (CARB vs. WattTime) warrants investigating the accuracy and reliability of the LCFS assumptions. Fermata Energy recommends that CARB consider re-evaluating the current CI methodology and updating the CI assumptions for the smart charging pathway calculations.

If WattTime data is correct, the current assumptions favor LCFS market participants (including Fermata Energy) by underestimating their CO_2 emissions, and therefore giving them access to more credits than they would otherwise be able to obtain using more granular real-time CI values. This leads to potential over compensation of market participants, and unnecessary costs to the program and the state. Improving the data accuracy will therefore improve the actual environmental impact of EV charging (including V2X), incentivize market players to develop better charge management strategies, and lead to lower LCFS program costs by ensuring participants are not overcompensated.

Lastly, Fermata Energy recognizes that optimization for CI's and V2X monetization
opportunities may sometimes conflict. The formula proposed on hourly CI accounting of V2X
264.4 net energy flows is not necessarily aligned with our economic interest nor that of our
commercial and residential customers. To avoid this misalignment, CARB should ensure that
sufficient financial incentives are available through the LCFS program so that participants are
incentivized to reduce the carbon emissions.

4. Support for Use of LCFS Holdback Funds for Grid-Supported V2X Programs

Fermata Energy supports CARB's proposal to use LCFS Holdback Funds on VGI and V2G
264.5 programs.[7] However, we urge CARB to ensure that funding for V2G programs be limited to only
those that use grid-supported or "grid-tied" technologies and use cases. Non-grid-tied forms of V2G, such as islanded backup power, do not provide the same decarbonization benefits to the grid. Fermata Energy agrees with the pre-approved uses for these other holdback projects. In addition, we proposed that the list of holdback projects be amended so that it is clearer that grid-tied V2G projects can qualify as both equity and non-equity holdback projects. The proposed regulation is unclear and it looks like V2G projects only qualify as non-equity holdback. This should be fixed as V2G projects can benefit the communities and individuals defined as equity in Section 95483 (c)(1)(A) 5.

Fermata Energy appreciates the opportunity to provide these comments in response to CARB's Proposed LCFS Amendments. We look forward to collaborating with CARB as they finalize the proposed amendments to LCFS.

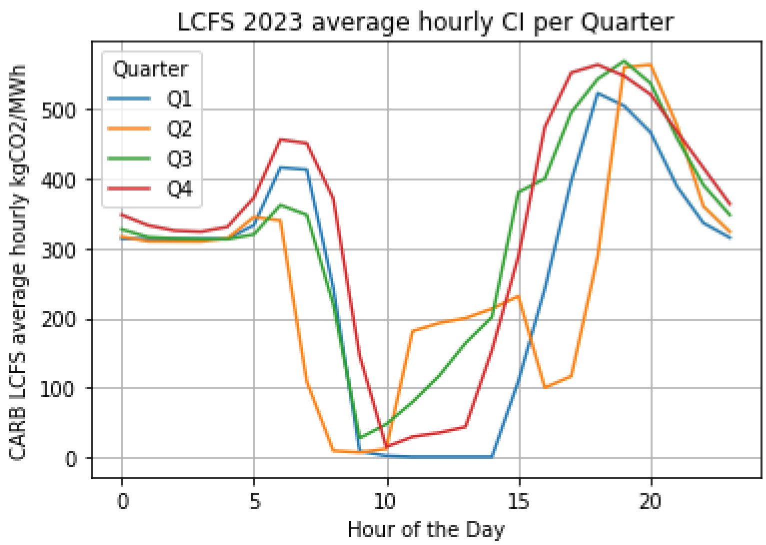
Appendix

Fig A Comparison of quarterly average hourly carbon intensity data



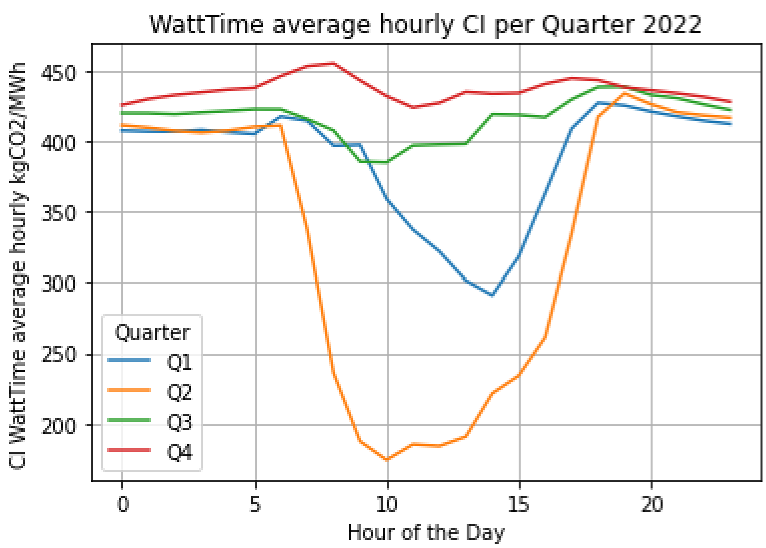


Table A - V2X emissions calculations for different user profiles and CI data sources

This table presents the environmental impact of two example V2X profiles in CA: one for a residential user and one for a V2G fleet vehicle, calculated using each of the two CI data sources for 2022

The charging and discharging profiles were obtained from Fermata Energy's optimization forecast. They represent the behavior of an EV owner aiming to maximize their economic revenue from V2X (detailed assumptions available upon request).

Units: kg CO2/year (for year 2022)	**LCFS Smart Charging CIs**	**WattTime MOER**
Residential	-716	-5,676
Fleet	6,559	-23,695

Note: A positive number reflects a net benefit in CO_2 reduction i.e. carbon removal due to V2X discharge offsetting V2X charging. CARB's CI assumptions would lead to an estimation of a net carbon benefit of a fleet V2X EV.

Liane Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: 2024 Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph:

I write on behalf of the Biotechnology Innovation Organization (BIO) - the world's largest biotechnology focused trade group with members that produce agricultural, environmental, industrial, and health care products – to comment on the California Air Resources Board (CARB) 2024 proposed amendments to the Low Carbon Fuel Standard (LCFS).

Specific to the pending rulemaking, BIO members produce both the feedstock and biofuels from which California's LCFS – along with the state's environment and economy - has benefitted so greatly the last 14 years.

Effective since 2011, California's LCFS has, by any standard, been wildly successful. In 2022 alone, the LCFS program helped to replace nearly two billion gallons of regular diesel fuels with a combination of renewable diesel, biodiesel, electricity, and hydrogen. Since compliance began, the program has helped replace more than 8.6 million gallons of diesel. In 2023, California hit an important milestone in its shift away from polluting fuel sources, with clean fuels replacing over 50% of the diesel used in the state in the first quarter of the year.

Thanks to the LCFS' technology neutral, market driven approach, California also receives significant volumes of other low carbon fuels, including ethanol, biomass-based diesel, and biomethane. To that end, since the inception of the LCFS, California has increased consumer choice by considerably diversifying the fuel mix and, in doing so, the state has doubled the volume of low-carbon fuel consumption. Collectively, alternative fuels supported by the LCFS displaced over 3.9 billion gallons of petroleum fuel in 2022 in California.

265.1 It is therefore puzzling then that CARB is proposing unworkable certification requirements instead of relying on existing and proven certification programs. Moreover, CARB's multiple references about "deforestation" in the documents accompanying the rulemaking seem to bely a general unawareness of the significant gains farmers have made in productivity over the years, leading to higher yields on the same or fewer acres, with less carbon intensive inputs. It also telling that the primary references for the "deforestation" claims come from European and not U.S. sources, leading one to wonder about the applicability and relevance of such information. Furthermore, the timber sector is in dire need of additional markets for low grade timber, so the idea that large swaths of land in the U.S. land is being deforested either in the agriculture or forestry sectors to benefit from California's LCFS appears unsubstantiated and misplaced.

265.2 Not only is proposed Section 95488.9(g): "Sustainability Requirements for Crop-Based and Forestry Based Feedstocks" not technology neutral, it appears aimed at eliminating the low carbon fuels that have been largely responsible for the program's overall success.

Frankly, it isn't clear why crop and forestry-based fuels are being singled out for meeting social and economic criteria, which have implications for any fuel pathway participating in the LCFS program, including electric vehicles. These additional criteria have the potential to add substantial administrative burden to both farmers and fuel producers, potentially creating barriers to participation in the LCFS. As such, this requirement should be dropped altogether.

265.3 BIO also wishes to take this opportunity to urge CARB push for the use of E!5 in California in whatever way possible. Although E!5 is technically not related to this rulemaking, it should be noted that California is one of only two states that does not permit the sale of E15.

Allowing E15 will help reduce the carbon intensity of the state's gasoline supply and cut emissions of criteria pollutants. In fact, the University of California-Riverside's Center for Environmental Research and Technology found that replacing E10 with E15 in California will significantly improve air quality. Additionally, E15 is EPA-approved for nearly all vehicles on the road and offers meaningful cost savings, but Californians are currently paying more at the pump because CARB has not yet approved E15.

Again, BIO appreciates the opportunity to comment on CARB's proposed amendments to the LCFS. Please feel free to contact me at gharrington@bio.org or (202) 365-6436 if you have any questions regarding BIO's comments.

Sincerely,

Gene Harrington
Senior Director, State Government Affairs, Agriculture & Environment

Life Cycle Assessment of U.S. Soybeans, Soybean Meal, and Soy Oil

Executive Summary

Life cycle assessment (LCA) is a rigorous study of the inputs and outputs of a particular product or product system which provides a scientific basis for evaluating the environmental impacts through each phase of the life cycle. LCA is an alternative to the single-criterion decision-making that currently guides many environmental choices.

This LCA is designed to be used by the United Soybean Board (USB) and the National Oilseed Processors Association (NOPA) to better understand the current state and environmental impact of the U.S. soybean industry's farming, processing, and oil refining operations. This report documents the methodology, data, details, and results of the LCA on the impacts of one kilogram (kg) of soybeans, one kilogram (kg) of soybean meal, one kilogram (kg) of crude soy oil, and one kilogram (kg) of refined soy oil produced in the United States. Primary data were obtained from direct information sources electronically collected from farmers and processors, with the assistance of USB and NOPA staff. Secondary data were obtained from the U.S. Department of Agriculture (USDA), U.S. Lifecycle Inventory (USLCI), and Ecoinvent databases.

Findings in this study provide a snapshot of industry performance based on acquired primary data from USB and NOPA members in support of this assessment:

- **Soybean cultivation data reflect 454 farms across 16 states.**
- **Soybean meal, crude soy oil, and refined soy oil data reflect 52 U.S. soybean processing plants and 27 co-located soy oil refineries operating across 18 states.**

Key Findings

Based on 2020 - 2021 harvesting yields reported by U.S. soybean farmers and 2021 operations and production data for U.S. soybean processing plants and co-located soy oil refiners as reported by NOPA members, **the global warming potential (GWP) profile decreased considerably for all evaluated U.S. soy commodities** compared to previously reported findings published in 2015 and 2010.

U.S. Soybeans, Soybean Meal & Soy Oil GWP Profile Reductions Since 2015

- 19% per kg U.S. soybeans
- 6% per kg U.S. soybean meal
- 22% per kg U.S. crude soy oil
  - 8% per kg U.S refined soy oil (produded at co-located processing/refining cites)

Previous life cycle assessments were commissioned by USB in collaboration with NOPA, each prepared and evaluated by different LCA practitioners. Data for oilseed processing operations was not formally collected as part of the 2015 assessment.*

Findings presented in this LCA show that herbicides, field operations, and fertilizer are the main drivers of most environmental impact categories assessed for soybean cultivation. **This analysis assumes an average production yield of 51 bushels per acre harvested, based on USDA estimates.** The percentages that each soybean agriculture component contributes to each impact category are shown in Table 0.1.

Table 0.1 – Agriculture Component Contributors by Impact Category

Impact Category	Field Operations	Fertilizer	Fungicide	Herbicide	Insecticide
Global Warming Potential	38.58%	24.37%	1.30%	31.92%	3.83%
Fossil Fuel Depletion	30.25%	27.82%	1.38%	36.61%	3.94%
Eutrophication	0.93%	90.69%	0.06%	8.08%	0.24%
Smog	51.00%	26.41%	0.58%	20.13%	1.87%
Acidification	28.81%	28.95%	1.09%	37.83%	3.32%
Ozone Depletion	5.92%	29.88%	2.22%	55.19%	6.80%
Carcinogenics	10.52%	51.12%	0.25%	37.06%	1.05%
Non-Carcinogenics	2.95%	22.71%	0.10%	7.68%	66.55%
Respiratory Effects	13.94%	42.22%	0.83%	40.51%	2.51%
Ecotoxicity	0.58%	4.73%	0.17%	36.48%	58.03%
Land Use	98.87%	0.57%	0.03%	0.42%	0.10%
Water Consumption	90.85%	5.99%	0.02%	2.92%	0.21%
Cumulative Energy Demand	25.44%	23.73%	1.78%	43.72%	5.33%

Soybean cultivation and harvesting, followed by energy usage in processing, are the main drivers of all impacts from soybean meal and soybean oil production. During processing, soybeans are

* The 2015 LCA study relied on NOPA member data for 50 processing plants based on previously reported data used for the 2010 study. In preparing the processing operations data used for the 2015 study, NOPA members reviewed the 2010 dataset and elected to revise only the electricity use input value. As such, the 2015 dataset reported the weighted average value instead of the upper bound value which was used for the 2010 study. This change was made so that the input value better reflected typical operating conditions at a soybean processing plant.

responsible for approximately 65% of the crude soy oil and soybean meal cradle-to-gate impacts, while energy usage is responsible for approximately 32%, depending on the impact category.

To account for the high amount of variability in agricultural practices, a range of sensitivity studies were conducted to evaluate the validity of the results and their dependence on the assumptions made throughout the LCA. The specific studies focused on:

- *Harvest yields* – testing the extent to which lower (41 bushels per acre, past yields) or higher (61 bushels per acre, average high yields) harvest yield assumptions affect impacts. Impact results at the lower and upper bound of the soybean yields show a 20% change over the baseline case (51 bushels per acre, average yield used in this study).

- *Diesel* – testing the sensitivity of results to the amount of diesel used during soybean farming. The baseline of 1.4 gallons of diesel per acre was compared to 2.5 gallons per acre, 5 gallons per acre, and 6 gallons per acre. Most categories remained constant or showed a small (1% - 5%) to moderate (5% - 21%) increase in impacts. Smog, however, showed significant increase in impacts (20% - 90% increase for soybeans, 17% - 70% for crude soy oil and soybean meal, and 12% - 52% increase for refined soy oil) due to the chemical reactions that occur when diesel is combusted.

- *Allocation method* – testing how utilizing economic allocation or energy content allocation instead of mass allocation affects environmental impacts attributed to each product. Since four times more meal is produced than oil, meal will always have a higher percentage of the impacts. However, results show that the gap between their respective shares of impacts decreases with economic and energy content allocations: 20% oil / 80% meal for mass allocation, 33% oil / 67% meal for allocation by energy content, and 41% oil / 59% meal for economic allocation.

Sensitivity analysis is a tool used in LCA to identify whether the model and results are dependent upon assumptions made. Assumptions and uncertainties are inherent within LCA and cannot be avoided; however, sensitivity analyses allow the practitioner to validate the strength of the assumptions used in a study. The results of the various sensitivity analyses show that for certain impact categories, there can be significant deviation in the results based on the assumptions made.

The sensitivity analyses conducted focused on the assumptions that would have the largest impact on the LCI (i.e., method of allocation and yield per acre). Both assumptions are integrally intertwined with all the LCI calculations, therefore, variation in these assumptions is expected to cause significant deviations. These assumptions were developed through primary data collection, expert validation, and research into industry common practices. As such, these assumptions have been determined to be the most accurate way to represent the soy industry in the United States.

Acknowledgements

Sustainable Solutions Corporation (SSC) gratefully acknowledges John Jansen and Jack Cornell from USB, Lauren Maul from Smith Bucklin, and Katie Vassalli from NOPA for their significant support and contributions throughout this project. They provided domain expertise on soybean agriculture and soybean processing, led surveys, and provided accurate primary data.

Additionally, SSC, along with USB and NOPA, would like to thank all the U.S. soybean growers and soybean crushers who provided valuable facility operations data and shared their institutional

knowledge about soybean farming, processing, and oil refining operations to ensure the high quality of this study.

List of Tables

1.0 Introduction

Life cycle assessment (LCA) is a powerful tool used to quantify the environmental impacts associated with the various stages of a product's life. This section provides a background and overview of LCA methodology and benefits.

1.1 Background

Soybean is a major commodity crop. Global production went from less than 50 million tons in the year 1970 to 161 million tons in the year 2000 and over 350 million tons in the year 2020. The U.S. and Brazil alone account for two-thirds of this production, with the U.S. being the largest producer and second largest exporter of soybeans. Soybeans comprise about 90% of U.S. oilseed production in the agricultural sector.

The use of LCA is growing rapidly in many industries including agriculture, food, chemical, and fuel. To support this growth and the increased demand for environmental profiles like carbon footprints, the United Soybean Board (USB) and the National Oilseed Processors Association (NOPA) commissioned an update to their life cycle assessment. This report is designed to benchmark the global warming potential of U.S. soybeans, soybean meal, and soy oil to help U.S. producers better assess and understand their contribution to the environmental impacts of U.S. soy lifecycle from farm gate (soybeans) to factory gate (soybean meal and soy oil). Findings of this study may also be used to evaluate what changes in industry practices may have contributed to the observed reductions between the data collection years (e.g. 2021, 2015 and 2010).

These datasets provided by USB and NOPA members will further be used to update public life cycle inventory database (e.g. U.S. GREET Model, Federal LCA Commons) for these commodities. These data may also be used to update LCA profiles of downstream products such as human foods, animal feeds, biofuels, and other industrial applications. This LCA is valuable to USB as a tool for competitive positioning.

1.2 Overview of Life Cycle Assessment

Life Cycle Assessment (LCA)[2] is an analytical tool used to comprehensively quantify and interpret the environmental flows to and from the environment (including emissions to air, water, and land, as well as the consumption of energy and other material resources) over the entire life cycle of a product (or process or service). By including the impacts throughout the product life cycle, LCA provides a comprehensive view of the environmental aspects of the product and an accurate picture of the true environmental tradeoffs in product selection.

The standards in the ISO 14040-series set out a four-phase methodology framework for completing an LCA, as shown in Figure 1.1: (1) goal and scope definition; (2) life cycle inventory

[2] This introduction is based on international standards in the ISO-14040 series, *Environmental Management – Life Cycle Assessment.*

(LCI); (3) life cycle impact assessment; and (4) interpretation. An LCA starts with an explicit statement of the goal and scope of the study; the functional unit; the system boundaries; the assumptions, limitations and allocation methods used; and the impact categories chosen. In the inventory analysis, a flow model of the technical system is constructed using data on inputs and outputs. The input and output data needed for the construction of the model are collected (including resources, energy requirements, emissions to air and water, and waste generation for all activities within the system boundaries). Then, the environmental loads of the system are calculated and related to the functional unit, to finalize the flow model. Inventory analysis is followed by impact assessment, where the LCI data are characterized in terms of their potential environmental impact (e.g., acidification, eutrophication, and global warming potential effects). The impact assessment phase of LCA is used to evaluate the significance of potential environmental impacts based on the LCI results. The impact assessment data are interpreted and validated by sensitivity analysis performed by the LCA practitioner to provide useful data to the company that commissioned the LCA.

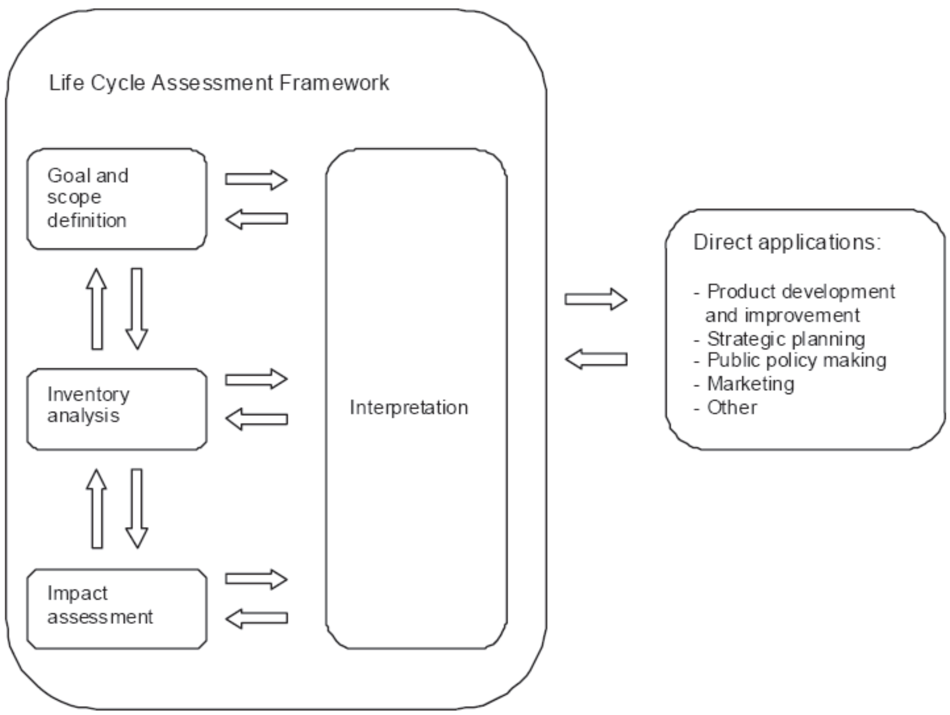

Figure 1.1 – The Four Stages of Life Cycle Assessment

The working procedure of LCA is iterative, as illustrated with the back-and-forth arrows in Figure 1.1. The iteration means that information gathered in a later stage can cause effects in a former stage. When this occurs, the former stage and the following stages must be reworked, taking into account the new information. Therefore, it is common for an LCA practitioner to work at several stages at the same time.

This LCA study is characterized as a "cradle-to-gate" study examining soybean cultivation and processing from raw material extraction through the processing facility gate. For this life cycle assessment, Sustainable Solutions Corporation (SSC) collected specific data on energy and material inputs, wastes, water use, emissions, and transportation impacts for the cultivation and processing of soybeans in the United States for the calendar year 2021. This LCA was conducted using SimaPro software with the National Renewable Energy Lab (NREL) USLCI database serving as the primary source of life cycle inventory data for secondary raw materials and processes. Where data were not available in the USLCI database, data from the Ecoinvent LCI database, private SSC LCI databases, and published reports were used. Data from any European databases were adapted using U.S. electricity impacts. The TRACI 2.1 impact assessment methodology was used to calculate the environmental impacts in this LCA. TRACI was developed by the U.S. Environmental Protection Agency (EPA) as a tool to assist in impact analysis in Life Cycle Assessments, process design, and pollution prevention. Impact categories include:

1. Global Warming Potential
2. Acidification
3. Carcinogens
4. Non-Carcinogens
5. Respiratory Effects
6. Eutrophication
7. Ozone Depletion
8. Ecotoxicity
9. Smog
10. Fossil Fuel Depletion
11. Water Consumption
12. Land Use
13. Cumulative Energy Demand

2.0 Goal and Scope Definition

The nature of life cycle assessment is to include a wide range of inputs associated with the product analyzed. Constraining the LCA scope is an essential part of the study. The following section defines the goal, scope, and boundaries of this LCA study.

This LCA went through a formal critical review by Marty Heller, AgResilience Consulting, LLC in January of 2024, as is required by ISO 14040 Standards for external release. The study was conducted following appropriate ISO standards and best practices and is intended to assist USB and NOPA with understanding the life cycle impacts of their products.

2.1 Goal of the Study

The goal of this analysis is to identify and quantify the environmental impacts associated with each stage in the cradle-to-gate life cycle of soybeans, soybean meal, crude soy oil, and refined soy oil, including soybean cultivation and harvesting, transportation, and processing.

USB and NOPA partnered together initially in 2010 to complete a similar analysis to ascertain the environmental impacts of soybeans, soybean meal, crude soy oil, and refined soy oil. In 2015, a second analysis was performed. For this study, NOPA members reviewed the 2010 LCA dataset and updated certain values to reflect a weighted average value. NOPA members concluded that this revision to the dataset was required in order to better represent the actual operating conditions required for soybean processing. See Appendix A for a detailed historical comparison of the results.

Intended Uses

LCA is a tool that can effectively be applied for process improvements, education and market support, environmental management, and sustainable reporting. USB and NOPA, who are the primary audience of the study, intend to use the study results for the following purposes:

- To understand and evaluate the impacts of soybeans, soybean meal, crude soy oil, and refined soy oil across the products' life cycle.
- To prepare for sustainable supply chain requirements, carbon taxes, and other potential policy requirements.
- For competitive analysis and positioning to analyze and evaluate claims or LCA information published in the future by competing industries.
- As a basis for future publication of a soybean, soybean meal, crude soy oil, and refined soy oil LCA if required by the market or if desired by USB and NOPA for marketing or competitive purposes.
- As a tool to illustrate the reduced environmental impacts to regulatory agencies (such as state/local environmental agencies or U.S. EPA) of agricultural practice, process, facility, or raw material improvements.
- To meet future requirements for green purchasing programs for the U.S. government, corporations, or other businesses.

2.2 Functional Unit

All flows to and from the environment within the system boundary (see Section 2.3 below) are normalized to a unit summarizing the function of the system. The functions of soybeans, soybean meal, crude soy oil, and refined soy oil are to be used in food manufacturing, biodiesel production, and industrial production.

Once the primary functions of the systems are defined, a functional unit is selected in order to provide a similar basis, consistent with the above-mentioned goals, for summarizing the LCA. The functional units utilized for this study are one kilogram (kg) of each product. This functional unit is consistent with the goal and scope of the study. Table 2.1 list specific details of soybeans, soy oil, and soybean meal.

Table 2.1 – Soybeans, Soybean Meal, Crude Soy Oil, and Refined Soy Oil Product Details

	Soybeans	Soybean Meal	Crude Soy Oil	Refined Soy Oil
Processing Location	United States	United States	United States	United States
Functional Unit	1 kg of soybeans	1 kg of soybean meal	1 kg of crude soy oil	1 kg of refined soy oil
Weight	1 kg	1 kg	1 kg	1 kg

The functional unit is the basis for reporting in an LCA. It provides a unit of analysis and comparison for all environmental impacts. Both crude soy oil and soybean meal are produced simultaneously. This required the allocation of impacts between the meal and the oil. Mass allocation was selected in order to remain consistent with previous studies.

2.3 System Boundary

This project considers the life cycle activities from resource extraction through processing facility gate. Figure 2.1 defines the system boundary for soybeans and soybean products included in this study. The study system boundary includes the transportation of major inputs to (and within) each activity, based on logistics data provided by USB and NOPA by common modes. Any site-generated energy and purchased electricity is included in the system boundary. The extraction, processing and delivery of purchased primary fuels, e.g., natural gas and primary fuels used to generate purchased electricity, are also included within the boundaries of the system. Purchased electricity consumed at the various site locations is modeled based on U.S. grid averages, using the models published in the USLCI and Ecoinvent cut-off databases.

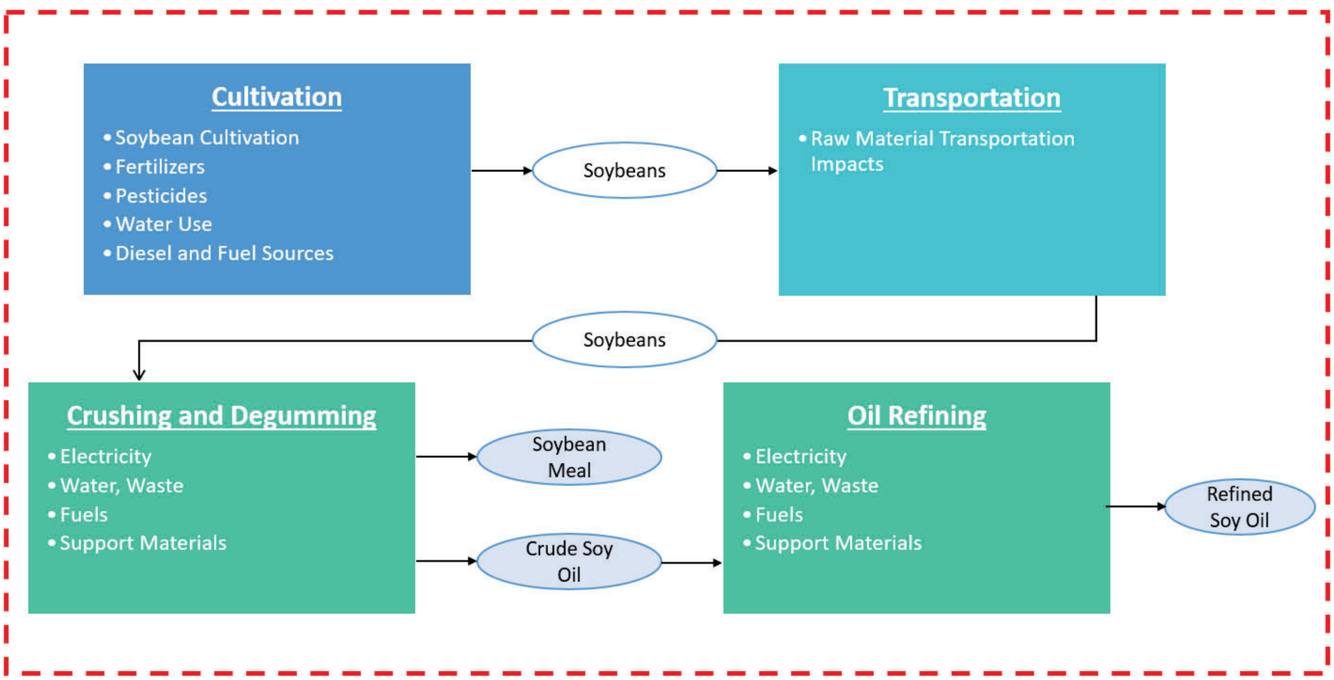

Figure 2.1 – System Boundary for Soybeans, Soybean Meal, Crude Soy Oil, and Refined Soy Oil

Both human activity and capital equipment were excluded from the system boundary. The environmental effects of manufacturing and installing capital equipment and buildings have generally been shown to be minor relative to the throughput of materials and components over the useful lives of the buildings and equipment. Human activity involved in the cultivation and processing of soybean products and their component materials no doubt has a burden on the environment; however, the data collection required to properly quantify human involvement is particularly complicated and allocating such flows to the production of the soybean products, as opposed to other societal activities, was not feasible for a study of this nature. Typically, human activity is only considered within the system boundary when value-added judgments or substituting capital for labor decisions are considered to be within the scope of the study; however, these types of decisions are outside this study's goal and scope. The details of the data excluded from the system boundary can be found in the subsequent inventory sections.

Table 2.2 – System Boundary Description

Included	Excluded
• Soybean cultivation, harvesting, and agricultural waste • Soybean transportation to processing facilities • Energy and inputs for soybean processing (the crushing and degumming process) • Energy and inputs in oil refining process	• Construction of capital equipment • Transportation of chemicals applied in fields • Maintenance of operation and support equipment • Human labor and employee commute

2.3.1 Cut-off Criteria

Processes whose total contribution to the final result, with respect to their mass and in relation to all considered impact categories, is less than 1% can be neglected. The sum of the neglected processes may not exceed 5% by mass and by 5% of the considered impact categories. For that a documented assumption is admissible.

For Hazardous Substances, as defined by the U.S. Occupational Health and Safety Act, the following requirements apply:

- The Life Cycle Inventory (LCI) of hazardous substances will be included if the inventory is available.
- If the LCI for a hazardous substance is not available, the substance will appear as an input in the LCI of the product if its mass represents more than 0.1% of the product composition.
- If the LCI of a hazardous substance is approximated by modeling another substance, documentation will be provided.

This LCA complies with the cut-off criteria since no known processes were neglected or excluded from this analysis outside of the specific items listed under "Excluded" in Table 2.2.

3.0 Data Sources and Modeling Software

The quality of the results of an LCA study are directly dependent on the quality of input data used in the model. This section describes the data quality guidelines used in this study, the sources from which the data were selected, the software used to model the environmental impacts, and any data excluded from the scope of the study.

3.1 Data Quality

3.1.1 Primary Data

Primary data were obtained from direct information sources electronically collected from farmers and processors with the assistance of USB and NOPA staff.

Soybean Cultivation Data

An online survey performed by USB in partnership with OBP, a marketing firm for agriculture, tourism, and food provided soybean cultivation primary data. Farmers were asked about soybean yield and moisture content, how much was spent on electricity and natural gas, fuel usage, waste produced, soil health, water quality related practices, and conversion of acres. 454 U.S. soybean farmers across 16 states completed the survey providing data for 2020 and 2021.

Soybean Processing and Soy Oil Refining Data

Primary data for soybean processing were based on NOPA member company responses to an electronic data collection survey performed by NOPA in partnership with SSC and Clean Fuels Alliance America. NOPA member-owned companies were asked to provide facility data about the transportation of inputs, processing and refining inputs/outputs, energy usage, and related sources.

For this study, NOPA provided SSC with aggregated data based on survey responses for 11 NOPA member companies, representing a total of 52 soybean processing plants and 27 co-located soy oil refineries operating across 18 states.

NOPA member facility data were submitted for calendar year 2021 NOPA Member Soybean Processing Operations based on analysis of aggregated NOPA member facility data. Individual facility data was anonymized and aggregated, then validated by NOPA's Certified Public Accountant. Analysis of the aggregated data was conducted by NOPA's Environmental Advisory Group prior to submission to SSC.

3.1.2 Secondary Data

Secondary data were obtained from USDA, USLCI and Ecoinvent databases. Where used, this study adopts critically reviewed data for consistency, precision, and reproducibility to limit uncertainty. Secondary data sources used are complete and representative of the U.S. in terms of the geographic and technological coverage and are a recent vintage (i.e., less than ten years old). Datasets that utilized data that were more than ten years old were updated with more recent data when possible. Secondary datasets used from the USLCI database utilize mass or energy allocation (process dependent) and datasets from the Ecoinvent database utilize economic or energy allocation. The allocation methodology implemented in secondary datasets is not always consistent with the allocation methodology used in this LCA study; however, those datasets represent the most appropriate options for the inventory.

Deviations from these initial data quality requirements for secondary data are documented in the report, found in Appendix B.

3.1.3 Data Quality Factors

The results of an LCA are only as good as the quality of input data used. Important data quality factors include precision (measured, calculated, or estimated), completeness (e.g., unreported emissions or excluded flows), consistency (uniformity of the applied methodology throughout the study), and reproducibility (ability for another researcher reproduce the results based on the methodological information provided). The primary data collected from USB and NOPA members were from the latest data available. Secondary datasets were taken from SimaPro databases, either USLCI or Ecoinvent. These databases are widely distributed and referenced within the LCA community and are either partially or fully critically reviewed.

Precision

There is a wide variability of farming, and this study attempts to capture this breadth of farming practices. The precision for primary data for processors is considered high; however, the uncertainty of the primary data has not been quantified. While the uncertainty of the primary data was not directly quantified, steps were taken to ensure the datasets were appropriate for use in the study. These steps included data validation with USB and NOPA personnel, data comparison to the previous U.S. Soybean LCAs, and evaluation against data published by credible sources, most notably the USDA survey database. More information on these steps can be found in the *Consistency* section.

Secondary data sets were used for raw materials extraction and processing, end of life, transportation, and energy production flows. The Ecoinvent database was used for most of the raw material data sets, such as chemical applications and fuels. Since the inventory flows for Ecoinvent processes are very often accompanied by a series of data quality ratings, a general indication of precision can be inferred. Using these ratings, the data sets used generally have medium-to-high precision. Precision for the datasets used from the USLCI database was not formally quantified. However, many data sets from the USLCI were developed based on well-documented industry averages with data quality indicators provided for each flow.

Completeness

The processes modeled represent the specific situations in the soybeans' cradle-to-gate life cycle. Data were evaluated for completeness to ensure that all relevant inventory items that were above the required reporting threshold, per the cut-off criteria, were included. System boundaries and exclusions are clearly defined in the sections above, and no other data gaps were identified.

Consistency

Farming survey data represented soy production for 2020 and 2021. Primary soybean cultivation data were obtained through a survey that was filled out by 454 soybean farmers across 16 states in the U.S. Soybean farms below 300 acres were excluded along with three outliers, establishing a sample size of 377 farms. Operations below 300 acres were determined to not be representative of the common U.S. cultivation practices based on discussions with industry experts. These smaller scale operations have much lower production volumes than larger ones and tend to utilize more unconventional cultivation methods due to the flexibility of managing lower volumes. These unconventional methods were excluded as they were expected to cause inaccurate reductions of environmental impacts, based on efficiencies of managing lower volumes, that do not correctly represent the U.S. soybean industry's common cultivation practices.

Individual farming survey responses were summed at the state level, for each inventory input and output, and benchmarked using the sum of total production at the state level, to calculate a state average LCI based on the interests of USB. A weighted average based on total production of individual states, relative to the total U.S. production calculated from the farm surveys, was used to develop the U.S. average LCI. Non-responses and zero values were included in the average when the majority of questions were answered by the respondent but were otherwise excluded. A statistical analysis of key energy inputs is presented in Table 3.1. The mean depicts the average of all survey respondents, while the weighted mean (i.e., state-level production-weighted average) captures the LCI values found in Table 5.1 on a per acre basis.

In the NOPA data, four outliers were examined to ensure that their exclusion would not alter or distort the results of the study and removed from the data as appropriate. Two outliers were found in the crushing and degumming process and two were found in the oil refining stage. Since the data represented a reasonable sample size over a 12-month period under normal operating conditions, the consistency is considered high. Secondary data were modeled using either USLCI or Ecoinvent databases as available. Proxies were only identified and used if secondary data were not available in these or other databases. This methodology provided consistency throughout the model.

Table 3.1 – Statistical Analysis of Survey Energy Data

Input	Unit	Weighted Mean	Mean	Minimum	Maximum	Standard Deviation	Coefficient of Variation
Electricity	MJ/acre	8.47E+01	6.38E+01	2.12E-02	9.00E+02	1.01E+02	119%
Natural Gas	MJ/acre	1.78E+02	2.66E+02	1.75E-01	8.68E+03	7.53E+02	423%
Diesel	gal/acre	5.15E-01	7.79E-01	1.00E-05	2.56E+01	2.44E+00	474%
Gasoline	gal/acre	8.12E-02	1.22E-01	1.18E-05	4.26E+00	4.56E-01	562%

Methodological consistencies between the previous studies were intentionally kept similar where relevant and appropriate to ensure a level of comparability exists between studies. This was done so that USB and NOPA could use this study internally to evaluate the effect of operational changes that have been implemented geared towards regulatory compliance in environmental impacts, increasing reliability, lowering costs, and improving sustainability.

Reproducibility

Most datasets are from nationally accepted and publicly available databases, ensuring reproducibility by an average practitioner. Confidential data from the plant would inhibit reproducing these results without access to the data.

Representativeness

The representativeness of the datasets is chosen to be for the United States, capturing average technologies of the major producers and distributors. Soybean processing and refining has data for a significant and highly representative fraction of producers. The average soybean acreage harvested in 2020 and 2021 was 84,457,500 acres. The total soybean acreage of the 377 farms that met the inclusion criteria was 378,592 acres, meaning the survey responses utilized in this study accounted for 0.45% of the total soybean acreage harvested in the U.S. between 2020 and 2021. However, soybean agriculture data are deemed to be representative of the average farming conditions stemming from the key U.S. geographies. Of the farming survey respondents, 39% are from the "I" states (Iowa, Illinois and Indiana), which correlates strongly with the states regarded as most relevant to soybean production.

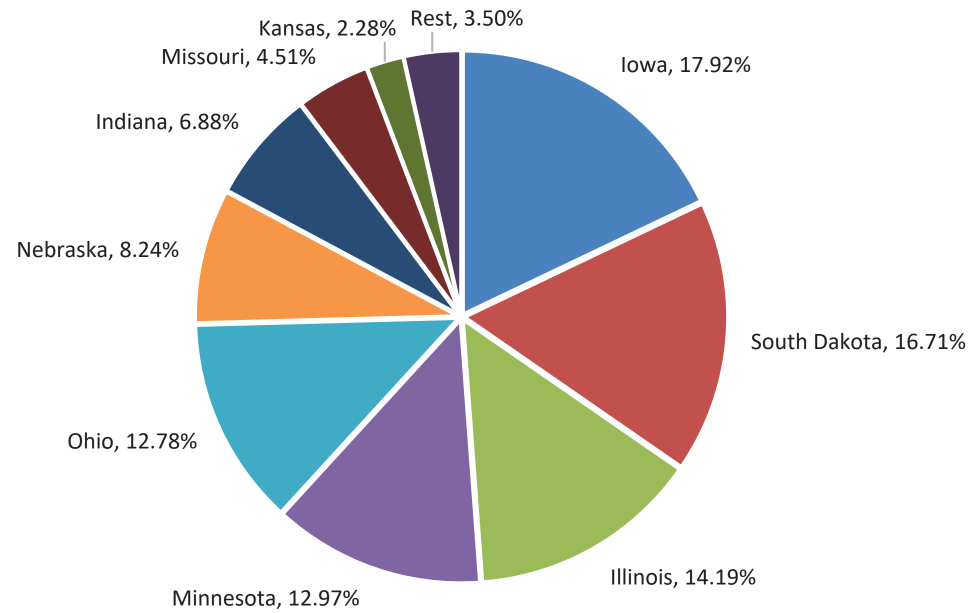

Figure 3.1 – Location of Farming Survey Respondents

Uncertainty

Uncertainty for primary energy data collected through the farming survey were quantified through statistical analysis. The collected data and allocation methodologies were determined to be accurate by USB and NOPA personnel based on the common industry practices, however, individual farming practices can vary widely due to a number of variables, so the range of input variables can vary significantly as shown in Table 3.1. Most of the secondary data sets in USLCI and Ecoinvent databases have some uncertainty information documented and varies per model.

The primary data from the manufacturer were from the latest data available, incorporating the most recent updates to the process into the model. Each dataset used was taken from SimaPro databases, either USLCI or Ecoinvent. These databases are widely distributed and referenced within the LCA community. The datasets use relevant yearly averages of primary industry data or primary information sources of the manufacturers and technologies. The uncertainty of each dataset is not formally quantitatively known. Each dataset is from publicly available databases, ensuring reproducibility. The datasets chosen are representative of the United States average technologies of the major producers and distributors and of recent and modern vintage. Below is a more detailed description of the datasets used in the model of raw materials extraction and processing for the major components of soybean cultivation and processing and refining of soy oil and soybean meal.

3.2 Data Sources

The United States is considered as the geographic boundary of this study. The reference year is 2021 since the primary soybean cultivation and processing data were gathered for that calendar year. Both primary and secondary LCI and metadata are used throughout the study.

3.2.1 Soybean Cultivation

Primary soybean cultivation data were obtained through a survey conducted by an independent third party in March of 2022. The third-party survey was focused on obtaining primary data from U.S. soybean farmers in order to accurately capture the practices used in U.S. soybean cultivation. Approximately 60,000 soybean farmers across the US were invited to participate in the survey by sharing data related to their growing metrics during the 2020 and 2021 growing seasons. The metrics of interest included yield; moisture content; spend on electricity, natural gas, and fuel; and volume of different types of waste produced. Of the participants invited, 454 soybean farmers spanning 16 different US states completed the survey. SSC determined that the states that responded to the survey represent an average approximation of U.S. soybean cultivation based on discussions with industry experts. Ranges in acreage, average yield per acre, and average moisture content were used to validate the discussions with industry experts. Data collected in the survey included the harvest acreage of alternate and cover crops. Soybeans are commonly grown in rotation with crops such as corn, wheat, and other crops in order to capture some of the operational benefits that exist utilizing this method. As such, the field operation inventory was allocated to soybean cultivation based on total harvest acreage.

During the data analytics process, SSC removed outliers from the utilized survey data by excluding data that could be deemed erroneous or irrelevant. An example of an erroneous data point is a response that indicated a yield of more than 100 bushels of soybeans per acre. An example of an irrelevant data point is a response from an operation with less than the minimum size which could accurately be classified as an "average" U.S. soybean operation. This number was determined to be 300 total acres. Operations below 300 acres were determined to not be representative of the common U.S. cultivation practices based on discussions with industry experts; and as such, these operations were excluded to focus the study on larger production practices.

Once outliers were removed from the dataset, the individual farming survey responses were summed at the state level, for each inventory input and output, and benchmarked using the sum of total production at the state level, to calculate a state average LCI based on the interests of USB. A weighted average based on total production of individual states, relative to the total U.S. production calculated from the farm surveys, was used to develop the U.S. average LCI on a 1 kg of soybean basis.

3.2.2 Soybean Processing

Data on primary soybean processing of soybean meal, crude soy oil, and refined soy oil were provided by NOPA, based on data gathered from 52 (crushing and degumming) facilities and 27 (oil refining) co-located facilities. All secondary data are taken from literature, previous LCI studies, and USDA and life cycle databases. The USLCI database (www.nrel.gov/lci) is frequently used in this analysis. Much of the LCI data residing in the USLCI database pertain to common fuels – their combustion in utility, stationary and mobile equipment inclusive of upstream or pre-combustion effects (i.e., raw material extraction). Generally, these modular data are of a recent vintage (less than ten years old). This study draws on these data for combustion processes, electricity generation, and transportation on a regional United States basis. These data are free and publicly available, and thus, offer both a high degree of transparency and an ability to replicate the results of the study; however, there are limitations, as some processes are missing for some of the products available in this LCI database, creating an issue with respect to completeness.

When United States data were not available for a product or process, North American or European Ecoinvent LCI database was utilized. This database contains over 3,500 LCI modules for processes and products, all of which have undergone peer review. The basic assumption when using these data is that North American and European production processes are generally similar to the United States, but that these data need to be adapted for United States circumstances (e.g., electricity grids, fuels and transportation modes and distances need to be modified to better reflect the United States operations). Such adaptation was conducted whenever necessary.

3.3 Modeling Software

SimaPro v9.2.0.2 software was utilized for modeling the complete cradle-to-gate LCIs for soybean agriculture, soybean meal, crude soy oil, and refined oil. All process data including inputs (raw materials, energy, and water) and outputs (emissions, wastewater, solid waste, and final products) are evaluated and modeled to represent each process that contributes to the life cycle of soybean products. The study's geographical and technological coverage has been limited to the United States. SimaPro was used to generate life cycle impact assessment (LCIA) results utilizing the TRACI impact assessment methodologies as well as single impact assessments (Global Warming Potential and Cumulative Energy Demand). See Section 4.1 for a description of the selected LCIA categories and characterization measures used in this study.

4.0 Life Cycle Impact Assessment (LCIA)

The environmental impacts of a product can be categorized and presented in many ways. This section briefly describes the methodology used to develop the impact assessment and defines the selected impact categories used to present the results. This section also lists assumptions of the study and describes the inherent limitations and uncertainty of the LCA results.

4.1 Impact Categories/Impact Assessment

As defined in ISO 14040:2006, "the impact assessment phase of an LCA is aimed at evaluating the significance of potential impacts using the results of the LCI analysis." In the LCIA phase, SSC modeled a set of selected environmental issues referred to as impact categories and used category indicators to evaluate the magnitude and significance of the potential environmental impacts. These category indicators are intended to "characterize" the relevant environmental flows for each environmental issue category to represent the potential or possible environmental impacts of a product system. The LCIA results are relative expressions and do not predict impacts on category endpoints, the exceeding of thresholds, safety margins, or risk.

ISO 14044 does not specify any specific methodology or support the underlying value choices used to group the impact categories. The value-choices and judgments within the grouping procedures are the sole responsibilities of the commissioner of the study.

The framework surrounding LCIA includes three steps that convert LCI results to category indicator results. These include the following:

1. Selection of impact categories, category indicators, and models.
2. Assignment of the LCI results to the impact categories (classification) – the identification of individual inventory flow results contributing to each selected impact indictor.

3. Calculation of category indicator results (characterization) – the actual calculation of the potential or possible impact of a set of inventory flows identified in the previous classification step.

To maximize the reliability and flexibility of the results, SSC used an established impact methodology for assigning and calculating impacts. The Tools for Reduction and Assessment of Chemical and other environmental Impacts (TRACI) methodology was used for all calculations of environmental impact. TRACI was developed by the U.S. EPA to assist in impact analysis in Life Cycle Assessments, process design, and pollution prevention.

4.2 Selected Impact Categories

While LCI practice holds to a consistent methodology, the LCIA phase is an evolving science and there is no overall generally accepted methodology for calculating all of the impact categories that might be included in an LCIA. Typically, the LCIA is completed in isolation of the LCI. The LCI involves the collection of a complete mass and energy balance for each unit process under consideration. Once completed, the LCI flows are sifted through various possible LCIA indicator methods and categories to determine possible impacts. Due to the United States focus of this LCA study, SSC used the TRACI LCIA methodology to characterize the study's LCI flows. Impact categories include:

1. *Ozone Depletion* (kg CFC-11 eq) – Certain chemicals, when released into the atmosphere, can cause depletion of the stratospheric ozone layer, which protects the Earth and its inhabitants from ultraviolet radiation. This radiation can have a negative impact on crops, materials, and marine life, as well as contributing to cancer and cataracts. This impact measures the release of those chemicals.
2. *Global Warming* (kg CO_2 eq) [IPCC AR5] – The methodology and science behind the Global Warming Potential calculation can be considered one of the most accepted LCIA categories. Because this study also tracks an overall life cycle carbon balance, the carbon dioxide emissions associated with biomass combustion are included in the Global Warming Potential calculation per the Intergovernmental Panel on Climate Change (IPCC) methodology. Carbon dioxide and other greenhouse gases are emitted at every stage in the life cycle. These gases can trap heat close to the Earth, and the global warming potential attempts to express the radiative forces of these different gasses and their contribution to global warming relative to the effect of carbon dioxide.
3. *Smog* (kg O_3 eq) – Under certain climatic conditions, air emissions from industry and transportation can be trapped at ground level where, in the presence of sunlight, they produce photochemical smog, a symptom of photochemical ozone creation. While ozone is not emitted directly, it is a product of interactions of volatile organic compounds (VOCs) and nitrogen oxides (NOx). The Smog indicator is expressed as a mass of equivalent ozone (O_3).

4. *Acidification* (moles SO_2 eq) – Acidification is a more regional rather than global impact affecting fresh water and forests as well as human health when high concentrations of SO_2 (and other chemical compounds) are attained. Acidification is a result of processes that contribute to increased acidity of water and soil systems, frequently through air emissions that contribute to acid rain. The largest contributors to acid rain are sulfur dioxide and nitrogen oxide. The acidification potential of an air emission is calculated relative to the acidification produced by SO_2 molecules; and therefore is expressed as potential SO_2 equivalents on a mass basis.

5. *Eutrophication* (kg N eq) – Eutrophication is the fertilization of surface waters by nutrients that were previously scarce. When a previously scarce or limiting nutrient is added to a water body, it leads to the proliferation of aquatic photosynthetic plant life. This may lead to the water body becoming hypoxic, eventually causing the death of fish and other aquatic life. Contributions from both nitrogen and phosphorus nutrient emissions are included in this indicator. This impact is expressed on an equivalent mass of nitrogen (N) basis.

6. *Human Health: Carcinogens* (CTU_h) – This impact assesses the potential health impacts of more than 200 chemicals. These are average general health impacts, based on emissions from the various life cycle stages, and do not take into account increased exposure that may take place in manufacturing facilities or on farms. These impacts are expressed in terms of Comparative Toxic Units (CTU_h). For human health this represents the estimated increase in morbidity in the total human population per kg of chemical emitted.

7. *Human Health: Non-Carcinogens* (CTU_h) – This impact assesses the potential health impacts of more than 200 chemicals. These health impacts are general, based on emissions from the various life cycle stages, and do not take into account increased exposure that may take place in manufacturing facilities. These impacts are expressed in terms of Comparative Toxic Units (CTU_h). For human health this represents the estimated increase in morbidity in the total human population per kg of chemical emitted.

8. *Respiratory Effects* (kg $PM_{2.5}$ eq) – This impact methodology assesses the potential impact of increasing concentrations of particulates on human health, as well as emissions that may contribute to particulate matter formation. Most industrial and transportation processes create emissions of very small particles which can damage lungs and lead to disease and shortened lifespans. This impact is expressed in terms of $PM_{2.5}$ (particulates that are 2.5 microns or less in diameter).

9. *Ecotoxicity* (CTU_e) – Many chemicals, when released into the environment, can cause damage to individual species and to the overall health of an ecosystem. Ecotoxicity measures the potential damage to the ecosystem that would result from releasing that chemical into the environment. This impact is measured in terms of Comparative Toxic Units (CTUe) and provides an estimate of the potentially affected fraction of species (PAF) integrated over time and volume per unit mass of chemical emitted.

10. *Fossil Fuel Depletion (MJ surplus)* – Maintaining fossil fuel resources for future generations is an essential part of sustainable development. This impact category measures the depletion of those resources in terms of megajoules (MJ). Fossil fuels are used as energy sources as well as raw materials for chemical production.
11. *Land Use* (m^2a crop eq) [ReCiPe] – Development of uninhabited land has been a major focus in the sustainable development industry, especially in the agricultural sector, where developing for socio-economic gain often results in long-lasting changes to the soil. This impact category primarily measures the impact of the occupation of land on terrestrial species by change of land cover and actual use of new land. The impact assessment also accounts for some transformation of land from pre-existing ecosystems. Land use characterizes intensities in terms of the equivalent square meters of annual cropland land use. There are various characterization factors for different land use types; including transformation, occupation, and relaxation.
12. *Water Consumption* (m^3) [ReCiPe] – Freshwater consumption is a growing concern in the global sustainability community because the freshwater resource available on the planet has been rapidly depleted over the past century. This indicator quantifies the removal of water from the watershed such that it is not available for use by other users. This impact category reports the inventory of water consumption that the process requires, in terms of cubic meters.
13. *Cumulative Energy Demand* (MJ) – This impact methodology assesses the total energy consumed throughout the life cycle. Cumulative energy demand is the sum of all energy sources drawn directly from the earth, such as natural gas, oil, coal, biomass, hydropower energy, and more. It takes into account all upstream and downstream processes and calculates the energy demand during different stages in the life cycle. This is an important impact category as higher energy demand translates to higher environmental impact. This impact category can help identify areas for improving and optimizing energy efficiency.

While the TRACI methodology supports fossil fuel depletion (on a global scale), it does not readily report primary energy use as an impact category. Primary energy use on a cumulative energy demand basis is tabulated and summarized as an impact category based on the LCI flows. Energy use is a key impact indicator over which soybean farmers and soybean meal and oil producers are likely to assert a considerable level of control and, therefore, is a good internal target for resource conservation. Cumulative energy demand is the sum of all energy sources drawn directly from the earth, such as natural gas, oil, coal, biomass, or hydropower energy. The total primary energy contains further categories, namely non-renewable, renewable, and feedstock energy. Yield is another key indicator where soybean farmers have some control, and it plays a significant role in determining the average environmental impacts of each functional unit. Additionally, farmers can focus their efforts on optimizing other agricultural inputs, such as fertilizers and herbicides, to maximize their impact reduction while reducing costs.

5.0 Soybean Production

5.1 Important Assumptions

Life cycle analysis requires that assumptions are made to constrain the project boundary or model processes when little to no data are available. In this study of soybeans, the following assumptions were made:

- Data from the survey are complete and representative of the U.S. average farming practice based on the methodology outlined in Section 3.2.
- Data collected in the survey included the harvest acreage of alternate and cover crops. Soybeans are commonly grown in rotation with crops such as corn, wheat, and other crops in order to capture some of the operational benefits that exist utilizing this method. As such, the field operation inventory was allocated to soybean cultivation based on total harvest acreage.
- USDA data were used for fertilizers & pesticides. Survey data were collected for yield but then it was decided to use USDA data for yield to maintain a conservative value for yield and remain in alignment with the USDA data used for field applications.
- Nitrate and phosphorus emissions were modeled following existing soybean models, which obtained their information from the USDA digital commons project. Emissions rates were calculated in alignment with the IPCC methodology for managed soils.[3] Dinitrogen monoxide emissions from anthropogenic nitrogen conversion were calculated as 1.11 kilograms per hectare, using the IPCC methodology for managed soils.
    - The calculation methodology included accounting for tier 1 direct and indirect emissions from synthetic fertilizer, manure, crop resides, and nitrogen fixation.
- When a material is not available in the available LCI databases, another chemical which has similar manufacturing and environmental impacts may be used as a proxy to represent the actual chemical. The Proxy Chemical List used in this analysis includes:
    - Alachlor as a proxy for acetochlor.
    - Pesticides without Ecoinvent background data and representing a minority fraction of material inputs were aggregated and proxied as generic pesticides.

5.2 Life Cycle Inventory

A thorough analysis of the material inputs and the product recipe was completed for the inventory of this study. The soybean cultivation inputs are listed in Table 5.1 below.

[3] IPCC N_2O Emissions from Managed Soils, and CO_2 Emissions from Lime and Urea Application

This section describes the cradle-to-gate life cycle inventory of soybeans.

Primary data on field operations for 2020 and 2021 were collected from surveys completed by U.S. soybean farmers. Secondary data on fertilizer use were obtained from the USDA 2020 census. A detailed analysis of the cultivation process was completed by SSC to understand soybean farming practices.

The process starts when soybean seeds are planted in the spring once soil temperature reaches sufficiently warm temperatures, typically in early spring. The type of seed depends on the location, as different soybean types are better suited to different climates and growing conditions. Water, fertilizers, and pesticides are used in custom quantities to help maximize yields without wasting resources. As soybean plants grow throughout the year, eventually their flowers turn into pods containing 1 - 4 seeds each. The soybeans are ready to harvest in the fall. In some countries, like Brazil, the warm climate allows for a second harvest in a year, but the U.S. is limited due to its cold winters. However, double cropping is practiced in some states in the South and southern Midwest, where winter wheat is planted in the fall and harvested in the spring. A variety of technologies are used by farmers throughout the process for everything from planting, irrigation, and fertilizing to harvesting.

Field operations data on electricity, fuel, and waste are based on survey responses from U.S. farmers. Of the respondents, 377 had soybean operations exceeding 300 acres and were included in the dataset. Production-weighted averages based on state-level production share were used to calculate the lifecycle inventory. The lifecycle inventory is based on an average yield of 51 bushels of soybeans per acre.

Soybean cultivation is modeled within LCA by considering energy, water, and materials which go into the field and waste and emissions that are outputs from the agricultural process.

Table 5.1 – U.S. Average Soybean Cultivation Inputs

Category	Product Recipe	Unit	Quantity per kg of Soybeans
Field Operations	Electricity	MJ	6.10E-02
	Natural Gas	MJ	1.28E-01
	Diesel	MJ	1.69E-01
	Gasoline	MJ	9.60E-02
	Propane	MJ	2.60E-02
	Water	m^3	4.18E-02
Fungicides	Picoxystrobin	kg	4.51E-05
	Pyraclostrobin	kg	3.95E-05
	Azoxystrobin	kg	3.69E-05

Category	Product Recipe	Unit	Quantity per kg of Soybeans
	Propiconazole	kg	3.43E-05
	Mefentrifluconazole	kg	3.33E-05
	All Other Fungicides	kg	1.70E-04
Herbicides	Glyphosate	kg	1.75E-03

	Bifentrhin	kg	4.77E-05
	Chloratraniprole	kg	4.44E-05
	All Other Insecticides	kg	1.86E-04
Fertilizer	Potash	kg	2.91E-02
	Phosphate	kg	1.80E-02
	Nitrogen	kg	5.56E-03
	Sulfur	kg	4.25E-03

5.3 Soybean Production Results

This section presents the results of the LCA study. It includes energy, global warming, and other quantified impacts for each of the TRACI impact categories.

The impacts for one kg of soybeans were estimated based on the inputs detailed in Table 5.1, utilizing a modified TRACI v2.1 methodology that includes water consumption and land use (see

Section 4.2 for methodology explanation). Figure 5.1, found below, shows the graphical analysis of the driving factors in each impact category. Absolute values can be found in Table 5.2.

Table 5.2 – U.S. Soybean Analysis per 1 kg of Soybeans

Impact Category	Unit	Field Operations	Fertilizer	Fungicide	Herbicide	Insecticide	Total

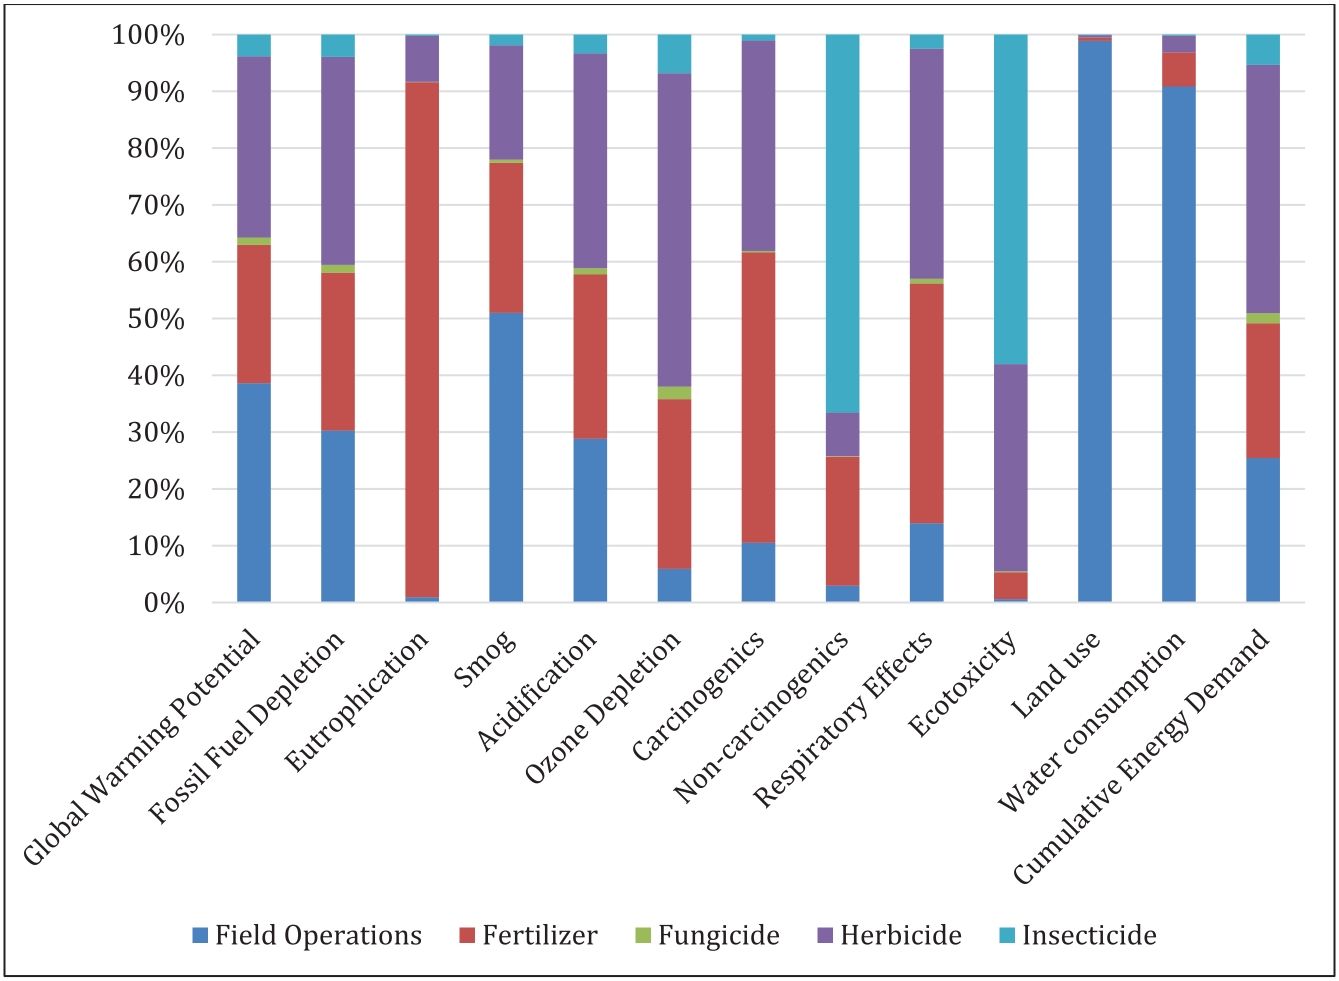

Figure 5.1 – U.S. Soybean Analysis per 1 kg of Soybeans

Figure 5.1 illustrates how each component is driving impacts in each of the 13 impact categories. Overall, field operations, fertilizer, and herbicides are significant contributors to impacts in most categories. Field operations are particularly substantial when it comes to land use and water consumption. Field operations include the measurement of the use of land, as well as energy and water inputs. Land use impacts are driven by operations, as agriculture requires vast quantities of land, and soybeans are an agricultural product. Similarly, while producing fertilizers and pesticides requires some energy, agriculture is much more energy-intensive due to the quantity of fuel needed to operate the equipment required to plant and harvest the soybeans.

Field operations, fertilizer, and herbicide are further analyzed next. Figure 5.2 and Table 5.3 show the breakdown of the different components that make up field operations.

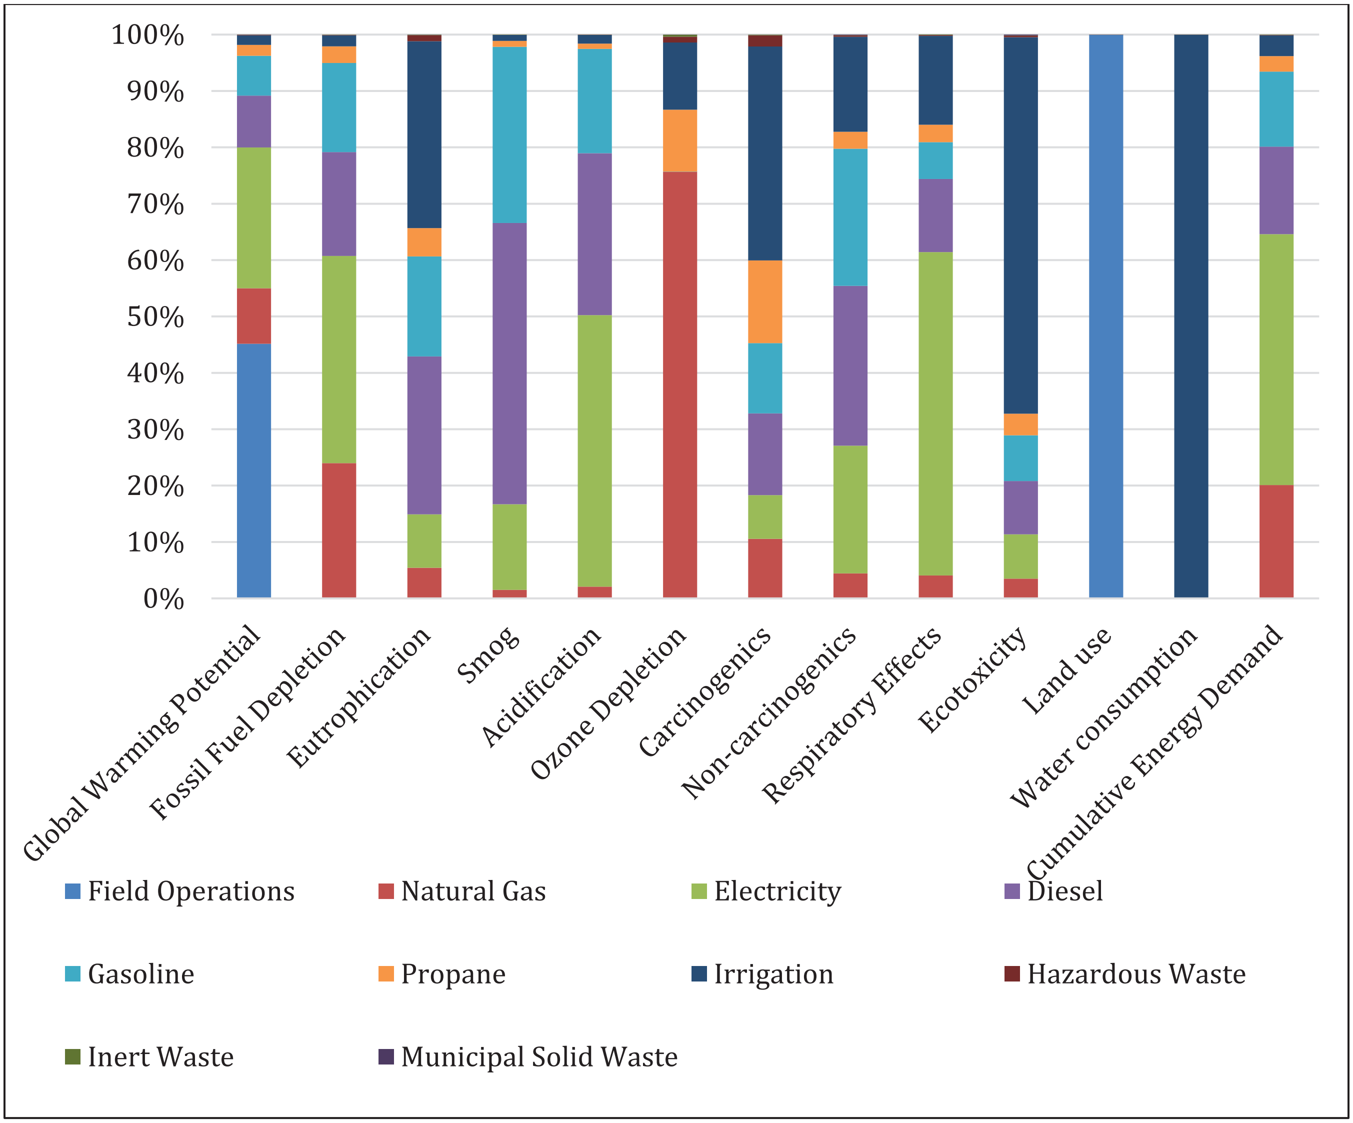

Figure 5.2 – Impacts of Field Operations per kg of Soybeans

Note: Field Operations includes impacts from land occupation and direct emissions to air from N_2O.

Table 5.3 – Impact of Field Operations per kg of Soybeans

Field operations, which accounts for land occupations and direct air emissions, are the main drivers of eutrophication and land use. Soybeans are a nitrogen fixing crop, meaning that they naturally release nitrogen, in the form of nitrate, into the ground. This can be carried by rain and irrigation into nearby bodies of water, such as lakes and rivers, resulting in higher levels of eutrophication. Figure 5.3 and Table 5.4 show the results of impacts from fertilizer.

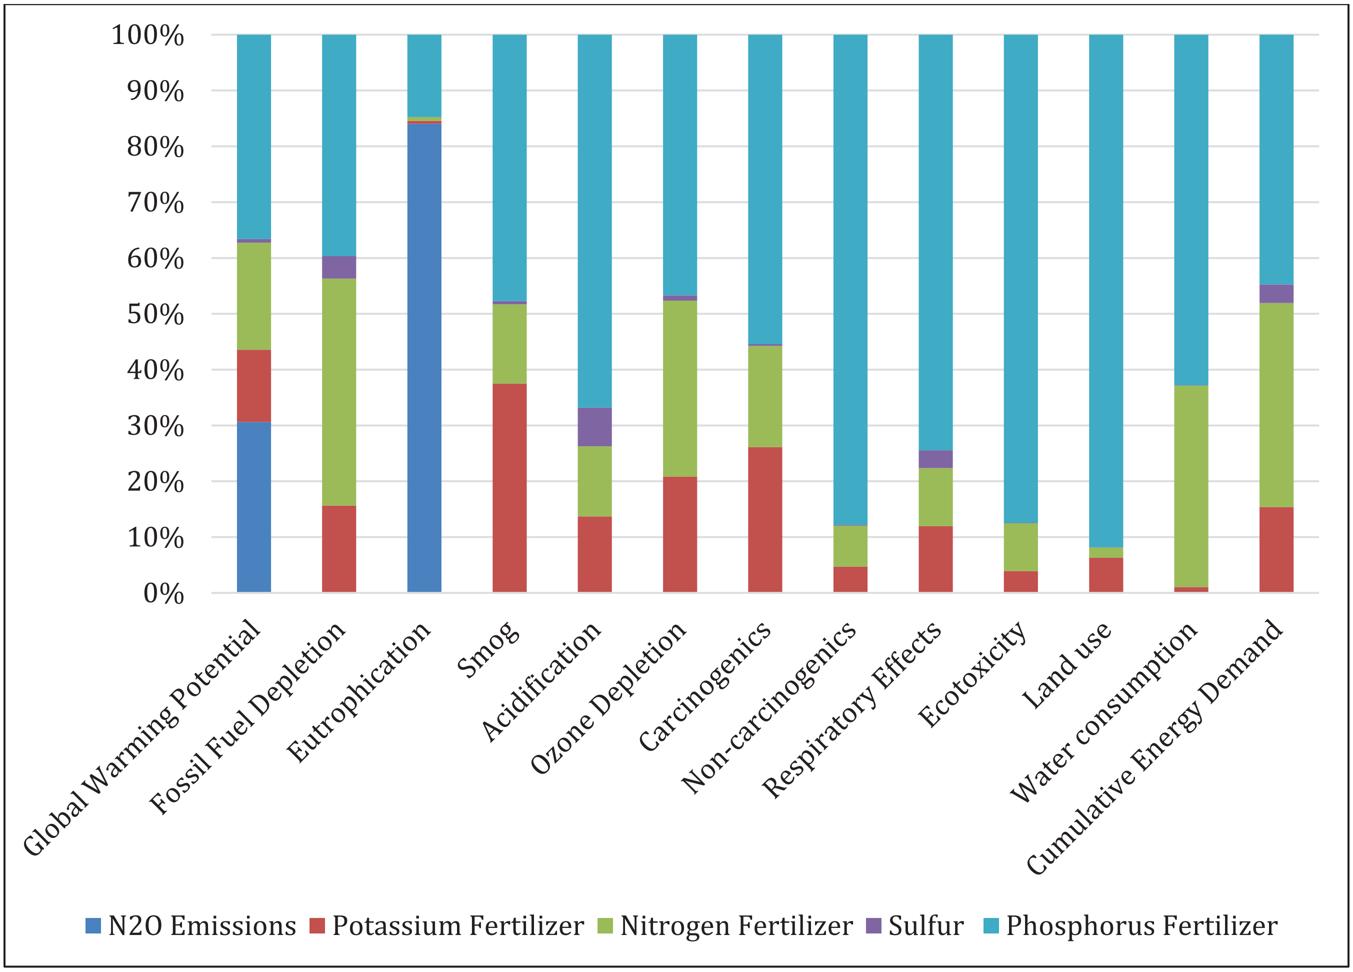

Figure 5.3 – Impacts of Fertilizer per kg of Soybeans

Table 5.4 – Impacts of Fertilizer per kg of Soybeans

The main driver of environmental impacts in most categories is phosphorus fertilizer. This is because phosphates represent the second most used fertilizer for farming soybeans and energy intensive materials in their upstream manufacturing (e.g., sulfuric acid). The one exception is eutrophication, which is dominated by fertilizer emissions to water. Fertilizer runoff, due to rain or irrigation, can reach nearby bodies of water, leading to algae blooms. The results shown above account for the soybean nutrient uptake from applied fertilizers, thus the impacts are attributed to excess fertilizer application.

There were also multiple types of herbicides, as illustrated in Figure 5.4. below.

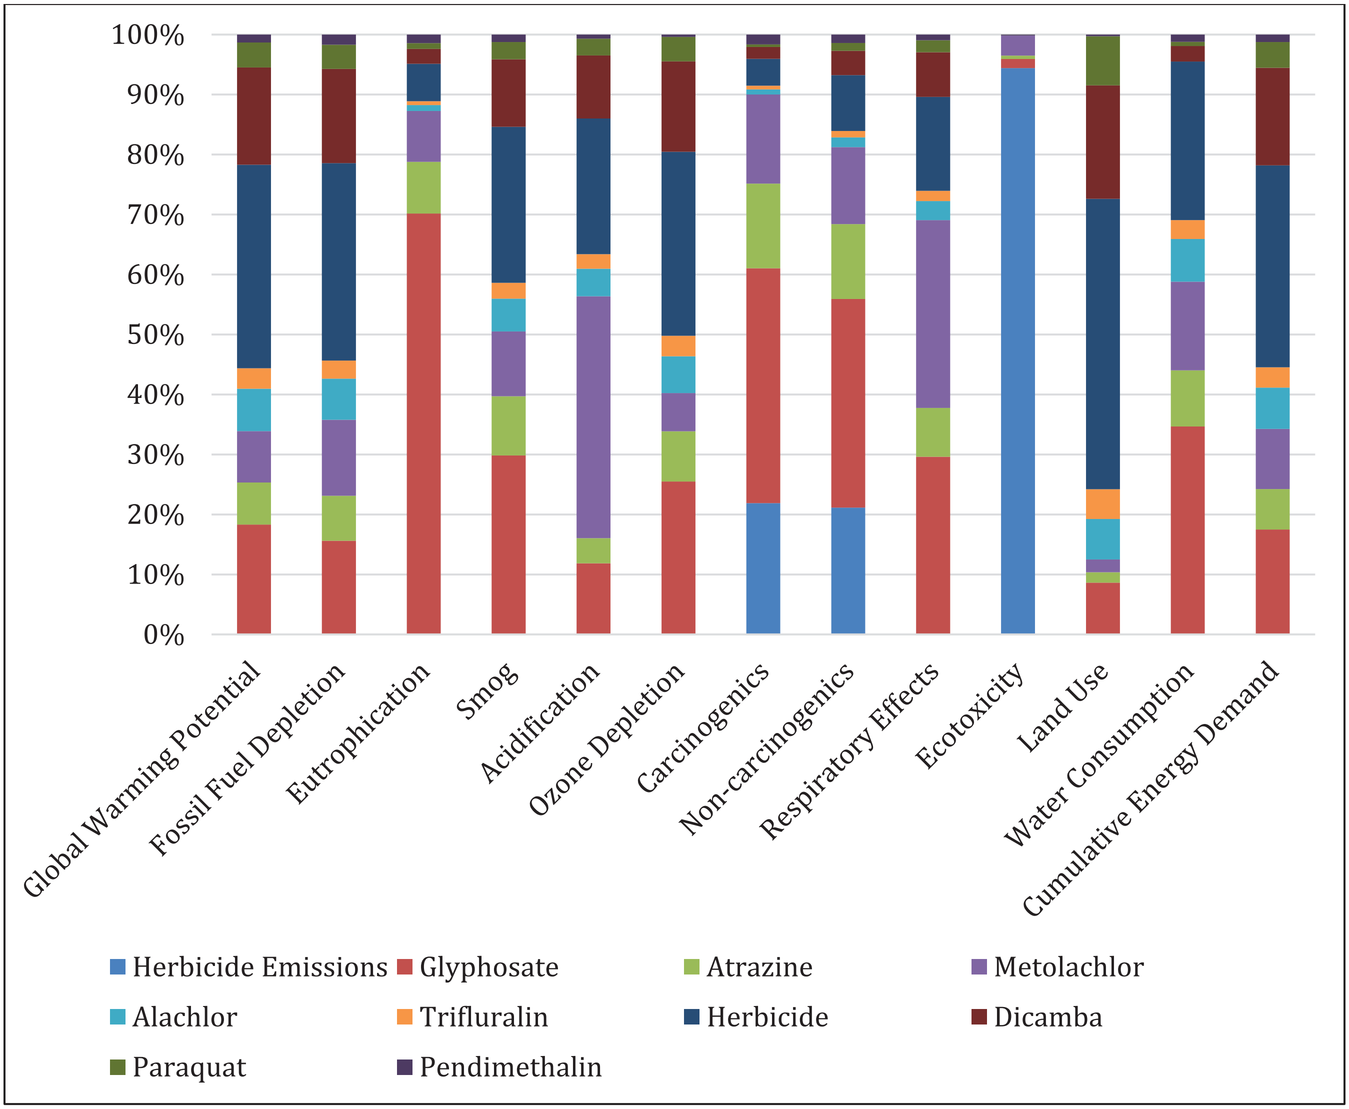

Figure 5.4 – Impacts of Herbicides per kg of Soybeans

Glyphosate and herbicide are the most prominent drivers of several impact categories. This is because of higher impact materials and energy needs in the synthesis of glyphosate and other herbicides.

Results were compared to those found in the previous LCA study performed by Quantis in 2015. This comparison can be found in Appendix A.

6.0 Crude Soybean Oil and Soybean Meal Production

6.1 Important Assumptions

In this study of soybean meal and crude soy oil, SSC made the following assumptions:

- Data provided are complete and representative of U.S soybean processing operations.
- Allocation by mass of co-products was used to distribute impacts to crude soy oil and soybean meal.
    - Allocation was determined to be 20.17% to crude soy oil and 79.83% to soybean meal, based on the mass output of the co-products when processing a single soybean. Consequently, the impacts associated (on a per kg basis) with soybean meal and soybean oil production are identical.
    - Soybean hull allocation was conducted by mass and included with soybean meal as it doesn't go through further processing after crushing phase.
- Hexane inputs are directly related to solvent loss, which typically occurs during extraction in the form of emissions. Actual hexane data were not collected for the purposes of this study. Instead, the total hexane emissions value used in the model is based on a solvent loss factor of 0.2 gallons/ton of conventional soybeans crushed as specified under the National Emission Standards for Hazardous Air Pollutants: Solvent Extraction for Vegetable Oil Production [40 CFR 63.2840].
    - Using this value provides a conservative estimate of total hexane emissions as it represents the maximum hexane loss threshold allowed under U.S. regulations. This approach is consistent with the previous 2015 and 2010 LCA studies where hexane emissions from soybean processing facilities were estimated using the same loss factor as designated under 40 CFR 63.2840.
- Soybeans are the primary material input and used in their entirety to produce soybean hulls, soybean meal, and crude soy oil. Soybean hulls are not discarded, rather they are either cycled back into the process to be added to soybean meal or sold as is to downstream manufacturers for further use.
    - Hull output values have been combined and reported as part of the meal hull output value. Soy hulls are not the primary outputs resulting from soybean processing, and thus were not called out as a specific product for analysis as part of this study.
- Actual total pounds of soybean inputs were reported as an aggregated average, while other input/output values were reported per 1,000 bushels with an assigned weight of

60 lbs. bu. Consequently, the aggregated data used in the analysis of soybean processing operations did not reflect a 1:1 mass balance for soybean inputs and product output values reported in Table 6.1.

- Other factors that may further contribute to the mass balance misalignment that resulted in the 1.03 kg soybean input value reported in Table 6.1:
    - USB reports an average bushel weight of 58.6 pounds,[4] whereas NOPA assumed an average bushel weight of 60 pounds in aggregating individual facility data for oilseed processing and co-located refining operations. This was done in order to align with data as reported in previous studies, and to maintain consistency with assumptions for hexane use based on the maximum threshold as allowed by EPA under 40 CFR 63.2840, identified above.
        - Actual bushel weight may vary due to a variety of product quality factors including amount of moisture within the soybean, amount of residual crop-waste and size of individual beans. Soybeans are sold as a commodity by bushel based on an average weight that is adjusted to account for product quality impacts.
    - There is a recognized material loss that occurs during processing due to dust generation and soybean hull spillage during the crushing and degumming process. Dust generation that is not captured by filter systems can be aggregated and incorporated back into the process for soybean meal production. Due to the variation in the number of cycles through the process, the output material is difficult to trace to a final system output. As such, the loss is captured as additional input material.
- All soybean products are transported by bulk via barge, railcar, tank truck, and/or pipeline.
- When a material is not available in the available LCI databases, another chemical which has similar manufacturing and environmental impacts may be used as a proxy, representing the actual chemical. The Proxy Chemical List used in this analysis includes:
    - Heat, onsite boiler, softwood mill average, NE-NC/MJ/RNA as proxy for "Biomass."
    - Heat, from steam, in chemical industry {RoW}| steam production, as energy carrier, in chemical industry | Cut-off, U" as proxy for "Purchased Steam."
    - Diesel as proxy for "Other Fuels."

[4] See Appendix D for crude soy oil and soybean meal inventory adjusted for USB bushel weight of 58.6 pounds.

6.2 Life Cycle Inventory

This section describes the cradle-to-gate life cycle inventory of soybean meal and crude soybean oil. Data on the soybean crushing and degumming process were collected from members of the National Oilseed Processors Association (NOPA) processing facilities located in the U.S. for the 2021 calendar production year. The participating processing plants provided resource transportation mode and distance data to support the calculation of raw material transportation flows. The transportation LCI data from the USLCI database (kg-km basis) were used to develop the resource transportation LCI profile.

Over 50 percent of NOPA member companies that participated in this study reported data for crushing and degumming as well as co-located refining processes. SSC completed a detailed analysis of the manufacturing process steps involved in the production of soybean meal, crude soybean oil, refined soybean oil, and specialty products following the solvent extraction stage to understand these production processes, as illustrated in Appendix C.

NOPA member soybean facilities operate seven days a week, 24 hours a day, 365 days a year and modifying its production schedule as needed to perform routine maintenance inspections, replace/repair equipment, address facility permitting requirements, advance facility modification/construction projects, etc. Transportation data was provided by NOPA to account for the delivery of soybeans at the processing facility. Soybeans are received at the processing facility by truck (84% of soybeans delivered); rail (13% of soybeans delivered); or barge (3% of soybeans delivered). Upon delivery, the first step is to grade the beans for moisture, damage, foreign materials, and color.

In the U.S. up to 13% moisture is allowed, though a moisture level within the range of 8-9% is typically observed. Some facilities may use non-invasive Near Infrared (NIR) to measure oil content as well. Following inspection, soybeans are sent to a temporary storage container.

From the storage bin. the soybeans are first dehulled, dried and cracked, either through a conventional or hot dehulling process. The hulls are ground and pelletized while the "crack" is rolled into thin flakes to expose the oil cells.

The flakes are then sent through an extractor where hexane is used to separate the oil from the flake. The flakes are then removed from the oil and hexane mixture, desolventized to remove residual solvent from the flakes, then toasted, dried and cooled before being ground into soybean meal. Concurrently, hexane is separated from the oil which can then be placed in a centrifuge to remove gums from the oil to produce degummed crude soybean oil.

Soybean hulls, meal and crude soy oil are co-products of NOPA member oilseed processing operations, and as globally traded commodities, all products must meet federal, state and industry standards in accordance with U.S. laws and regulations. Consequently, because these commodities are produced simultaneously, this study allocates the impacts between meal and oil as equal. Mass allocation was selected in order to remain consistent with previous studies.

To produce soybean meal and crude soy oil, energy, water, and materials go into the process and wastewater and emissions are outputs from the manufacturing process. SSC conducted an inventory based on the allocation described above. Table 6.1 details the process inputs and outputs.

Table 6.1 – Soybean Processing Inventory

Energy Inputs	Unit	Quantity per kg of Soybean Meal or Crude Soy Oil
Electricity	kWh	3.90E-02
Natural Gas	mmbtu	6.71E-04
Coal	mmbtu	5.55E-05
Biomass	mmbtu	5.18E-06
Other Fuels	mmbtu	8.13E-06
Purchased Steam	mmbtu	5.20E-04
Material Inputs	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Soybeans	kg	1.03E+00
Hexane	kg	5.52E-04
Water	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Inflow	L	3.54E-01
Wastewater	L	1.41E-01
Evaporated Water	L	2.13E-01
Transportation	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Truck	kgkm	7.20E+01
Rail	kgkm	4.82E+01
Barge	kgkm	2.21E+01
Emissions	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Hexane	kg	5.52E-04
Note: Soybean meal and crude oil are co-products resulting from crushing operations. Consequently, inventory data was unable to be allocated to product specific processes and the product values are the same.		

6.3 Crude Soy Oil and Soybean Meal Production Results

Processors purchase the raw materials and control operational processes used to produce meal and oil; however, their ability to directly influence the production of raw materials, and thus environmental impact, is typically outside their control. Environmental impacts that occur in soybeans shipping, processing, and final product shipping are directly under NOPA members' purview. This puts much of the environmental impact of the final product out of the control of soybean processors unless material substitutions can be made. However, since this is a cradle-to-gate study that ends at the factory gate, final product shipping is not be included in this paper.

6.3.1 Crude Soy Oil and Soybean Meal Processing Impacts ONLY

Energy is the main component of the crushing and degumming process to manufacture soybean meal and crude soybean oil. It is also required to grow or extract, process, and ship raw materials to the plant.

Table 6.2 below lists the amount of cumulative energy consumed during the manufacturing process for crude soy oil and soybean meal most directly under the control of NOPA member processing facilities. All the energy consumption was calculated in megajoules (MJ), using the cumulative energy demand impact category defined in Section 4.2, to allow for comparison of energy consumption across all uses. Cumulative energy demand is the sum of all energy sources drawn directly from the earth, and accounts for all upstream and downstream processes. This energy consumption is based on the original manufacturing inventory in Section 6.2 where allocation and fuels and energy sources are discussed.

Table 6.2 – Energy Use During Soybean Processing

Manufacturing Energy Consumption	Energy Use per kg of Crude Soy Oil or Soybean Meal (MJ/kg)
Electricity	1.40E-01
Natural Gas	7.08E-01
Coal	5.85E-02
Biomass	5.46E-03
Other Fuels	8.58E-03
Purchased Steam – Natural Gas	2.94E-01
Purchased Steam – Coal	7.18E-02
Purchased Steam – Biomass	1.78E-01
Purchased Steam – Liquid Petroleum Gas	4.39E-03
Total	**1.47E+00**
Note: Soybean meal and crude oil are co-products resulting from crushing operations. Consequently, the energy use data was unable to be allocated to product specific processes and the product values are the same.	

Figure 6.1 shows the same energy breakdown in a pie chart. This further illustrates the overwhelming contribution that natural gas (and purchased steam from natural gas) contributes to energy used to produce crude soy oil and soybean meal in the U.S.

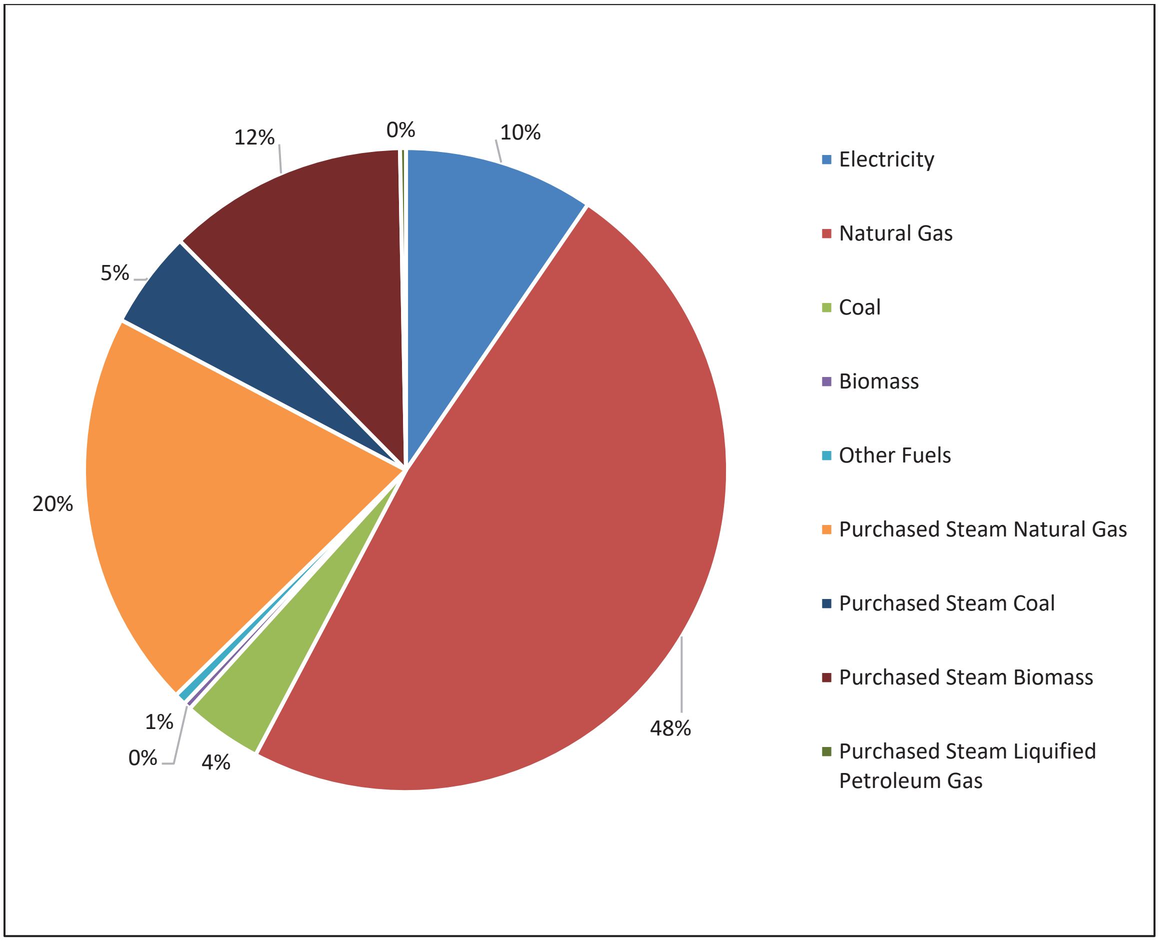

Figure 6.1 – Energy Breakdown for Crude Soy Oil and Soybean Meal Production

The impacts of processing of one kilogram of soybean meal or one kilogram of crude soybean oil from the inputs included in Table 6.1 were estimated utilizing the modified TRACI v2.1 methodology. The results are displayed in Figure 6.2 and quantified in Table 6.3.

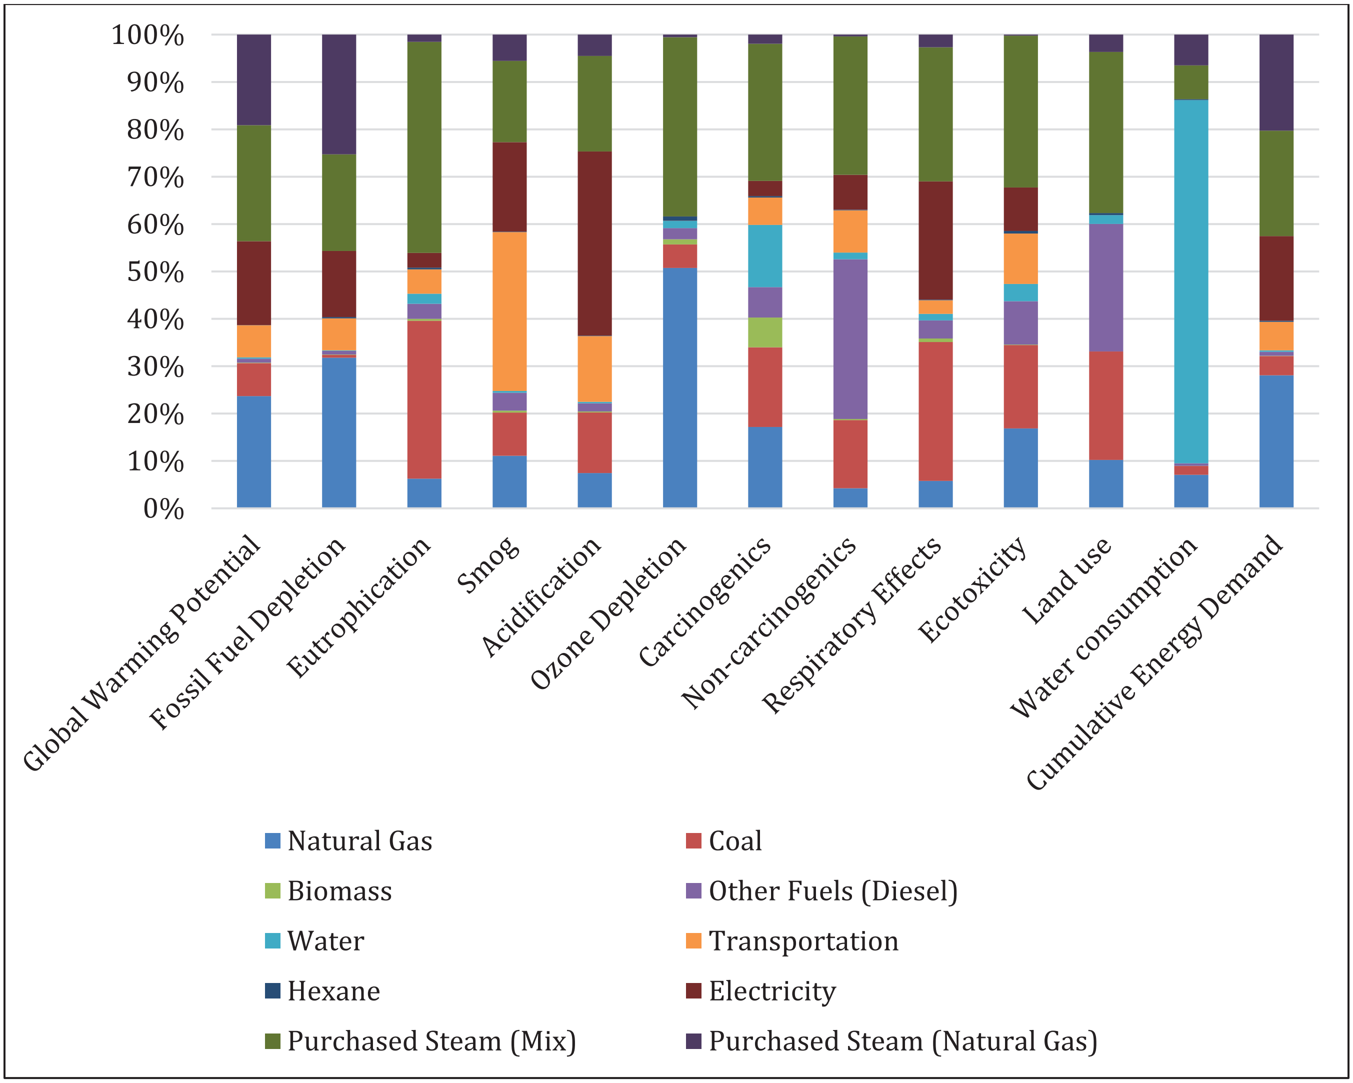

Figure 6.2 – Impacts of Soybean Processing for 1 kg of Soybean Meal or 1 kg Crude Soy Oil

As expected, natural gas and purchased steam are significant components of most impact categories, followed by electricity. Natural gas is typically used for heating and steam generation which is used during drying and oil/solvent recovery process steps.

Table 6.3 – Impacts of Soybean Processing for 1 kg of Soybean Meal or 1 kg Crude Soy Oil

Table 6.4 displays the breakdown of Global Warming Potential (GWP) from the manufacturing of crude soy oil and soybean meal in the U.S. Similar to energy use, the majority of GWP in the manufacturing process is from purchased steam and natural gas consumption, as well as electricity.

Table 6.4 – GWP from the Manufacture of Crude Soy Oil and Soybean Meal in the U.S.

Processing Component	Crude Soy Oil or Soybean Meal GWP (kg CO_2 eq/kg)
Natural Gas	2.98E-02
Coal	8.75E-03
Biomass	9.75E-05
Other Fuels (Diesel)	1.07E-03
Water	3.65E-04
Transportation	8.50E-03
Hexane	6.07E-05
Electricity	2.22E-02
Purchased Steam (Mix)	3.08E-02
Purchased Steam (Natural Gas)	2.40E-02
Total	**1.26E-01**

Note: Soybean meal and crude oil are co-products resulting from crushing operations. Consequently, the GWP data was unable to be allocated to product specific processes and the product values are the same.

Figure 6.3 shows the same GWP breakdown in a pie chart. This further illustrates the contribution that purchased steam, natural gas, and electricity contribute to GWP from the production of crude soy oil and soybean meal in the U.S.

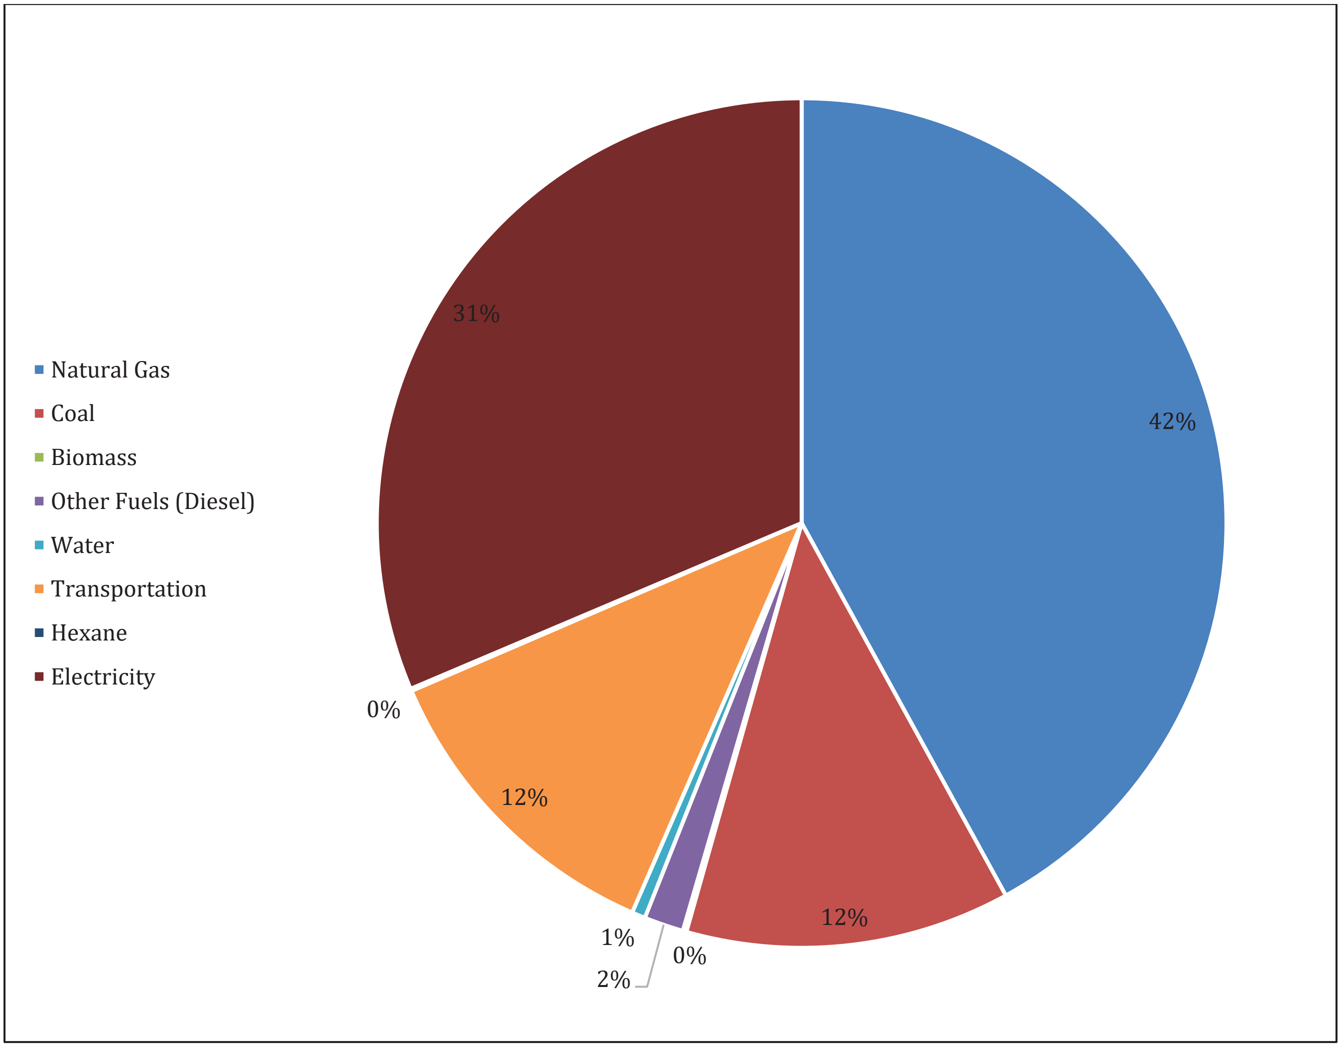

Figure 6.3 – GWP of 1 kg of Crude Soy Oil or 1 kg of Soybean Meal

6.3.2 Overall Impacts

Besides energy demand and carbon emissions during processing, the soybeans also have embodied impacts. SSC ran a modified TRACI analysis to include the soybeans needed for making 1 kg or crude soy oil or 1 kg of soybean meal, as presented in Table 6.1. Results are displayed in Figure 6.4, and specific numbers are included in Table 6.5 and Table 6.6.

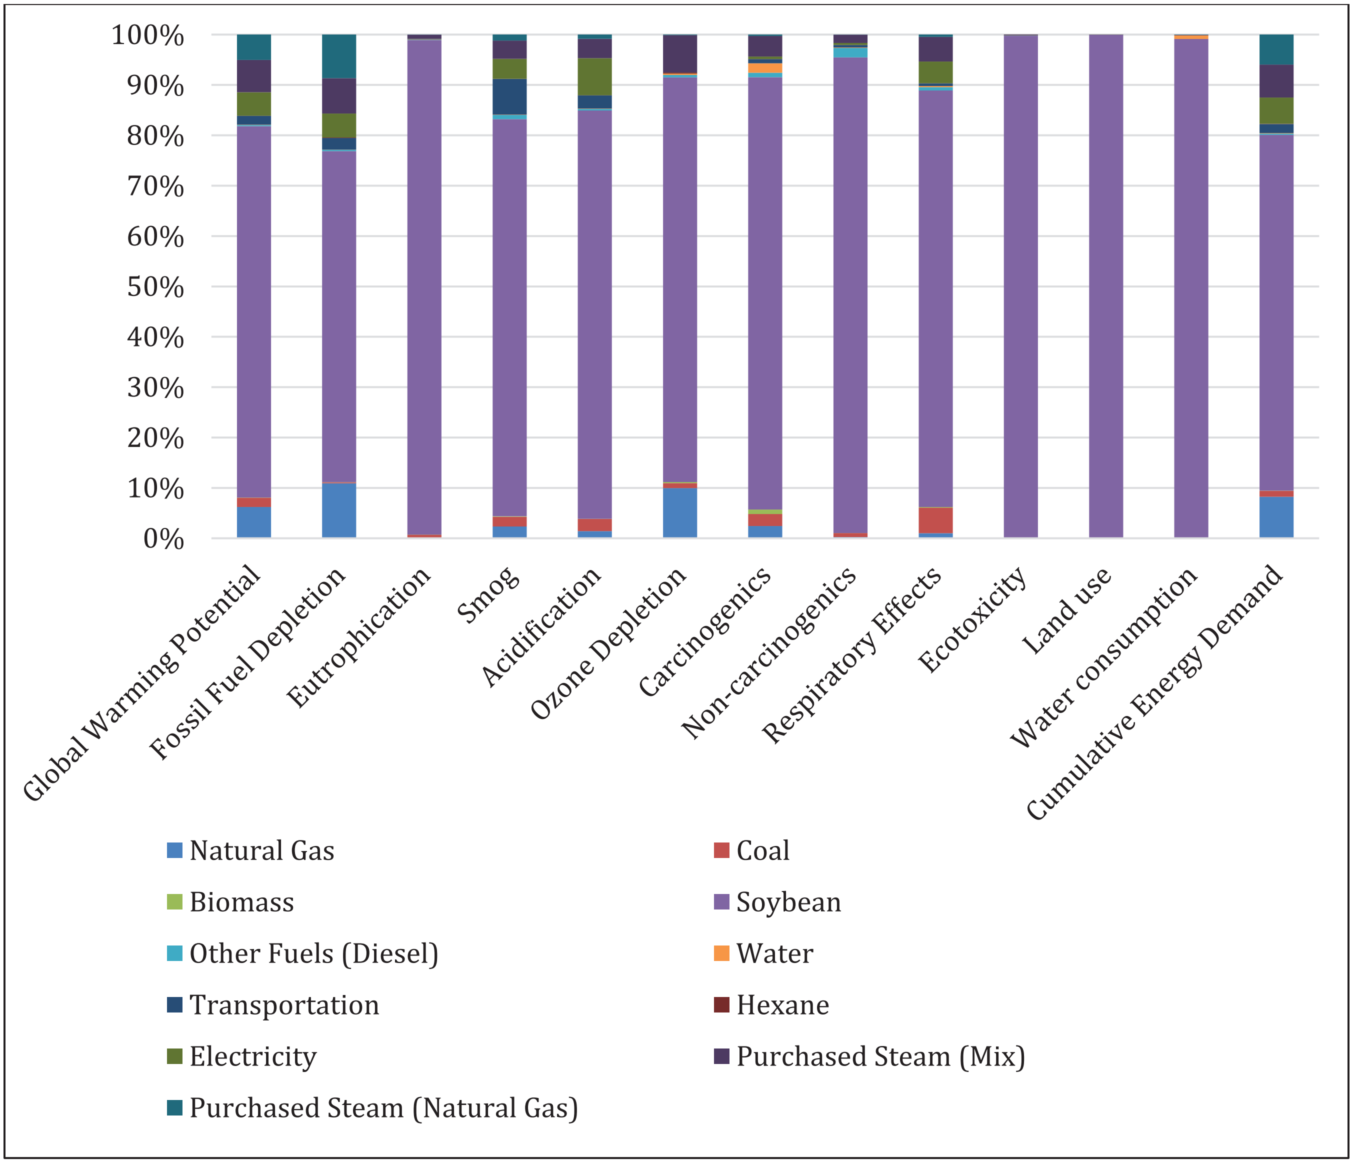

Figure 6.4 – Overall Impacts of the Crushing and Degumming Process for 1 kg of Crude Soy Oil or 1 kg of Soybean Meal

Table 6.5 – Environmental Impacts from Producing 1 kg of Crude Soy Oil

As shown in the figure above, the manufacturing impacts are dominated by the soybeans. This is because soybeans are the only ingredient in making crude soybean oil and soybean meal. Furthermore, growing soybeans is a process that takes several months before a harvest. This is more energy and resource-intensive than processing after harvesting. These results were also compared to the 2015 study, which can be found in Section A.2 of Appendix A.

7.0 Refined Soy Oil Production

7.1 Important Assumptions

In this study of refined soy oil, SSC made the following assumptions:

- Data provided are representative of U.S soy oil refining operations. NOPA member companies provided soy oil refinery data for 27 refineries co-located with soybean processing plants that produce crude soy oil and soybean meal.
- Crude soy oil is the primary material input used in the production of refined oil. Depending on plant design and co-location of processing and refining operations, crude soy oil may be delivered as degummed or not degummed oil.
    - Crude soy oil inputs were determined based on total percentage of degummed (39%) and not degummed (61%) crude soy oil reported by NOPA member companies.
- Actual total pounds of crude oil inputs were reported as an aggregated average, while all other input/output values were reported based on unit per short tons refined. Consequently, the aggregated data used in the analysis of soy oil refining operations did not reflect a 1:1 mass balance for crude soy oil inputs and refined oil output values reported in Table 7.1.
- Assumptions outlined in Section 6.1 also contributed to mass balance misalignment that resulted in the 1.02 kg crude soy oil equivalent value.
- This study assumes crude oil was delivered to the refinery from the processing plant via intra-facility piping, due to the co-located nature of the facilities represented in data provided. However, some facilities may also receive crude oil inputs from other transportation modes (e.g., truck, barge, rail). Refineries which are not co-located with a processing plant will typically receive crude soy oil by truck, rail or barge. For this reason, secondary transportation data were used for analysis.
- When a material is not available in the available LCI databases, another chemical which has similar manufacturing and environmental impacts may be used as a proxy, representing the actual chemical. The Proxy Chemical List used in this analysis includes:
    - Diesel as proxy for "Other Fuels."

7.2 Life Cycle Inventory

This section describes the life cycle inventory of refined soy oil. Data were collected from NOPA members for 27 soy oil refineries that are co-located with crushing operations. Once the solvent has been separated from the oil (discussed under Section 6.2 above and illustrated within Appendix C), crude oil is placed in a centrifuge to remove gums and soap stocks from the oil. Soy oil may be sold at this stage as “crude, degummed soy oil,” primarily as a feedstock for vegetable oil refining.

After degumming is completed, the oil is run through diatomaceous earth to take out impurities. Soy oil may be sold at this stage as “once refined soy oil”, primarily as a feedstock for the production of biodiesel.[5] The next step is to modify color and clarify the oil using bleaching clays. Soy oil may be sold at this stage as “once refined and bleached soy oil”, primarily as a feedstock for the production of renewable diesel and sustainable aviation fuel.[6] Finally, the soy oil may undergo a final deodorization step to meet U.S. Department of Agriculture and U.S. Food and Drug Administration product quality standards. Soy oil sold following this stage are typically used in the manufacturer and production of animal feed and human food applications.[7]

An inventory detailing the process steps for soy oil refining are shown in Table 7.1. The term inventory is used in LCA to refer to the list of inputs and outputs that are required to achieve the product function unit (e.g., 1.0 kg for purposes of this LCA).

Table 7.1 – Soy Oil Refining Inventory

Energy Inputs	Unit	Quantity per kg of Refined Soy Oil
Electricity	kWh	6.09E-02

7.3 Refined Soy Oil Environmental Impacts

7.3.1 Oil Refining Impacts ONLY

Crude soy oil can be further processed to become refined soy oil. The refining process consists of eliminating any impurities from the crude soy oil. SSC estimated the impacts of this process with the modified TRACI methodology based on the inputs included in Table 7.1 and are displayed in Figure 7.1 and quantified in Table 7.2.

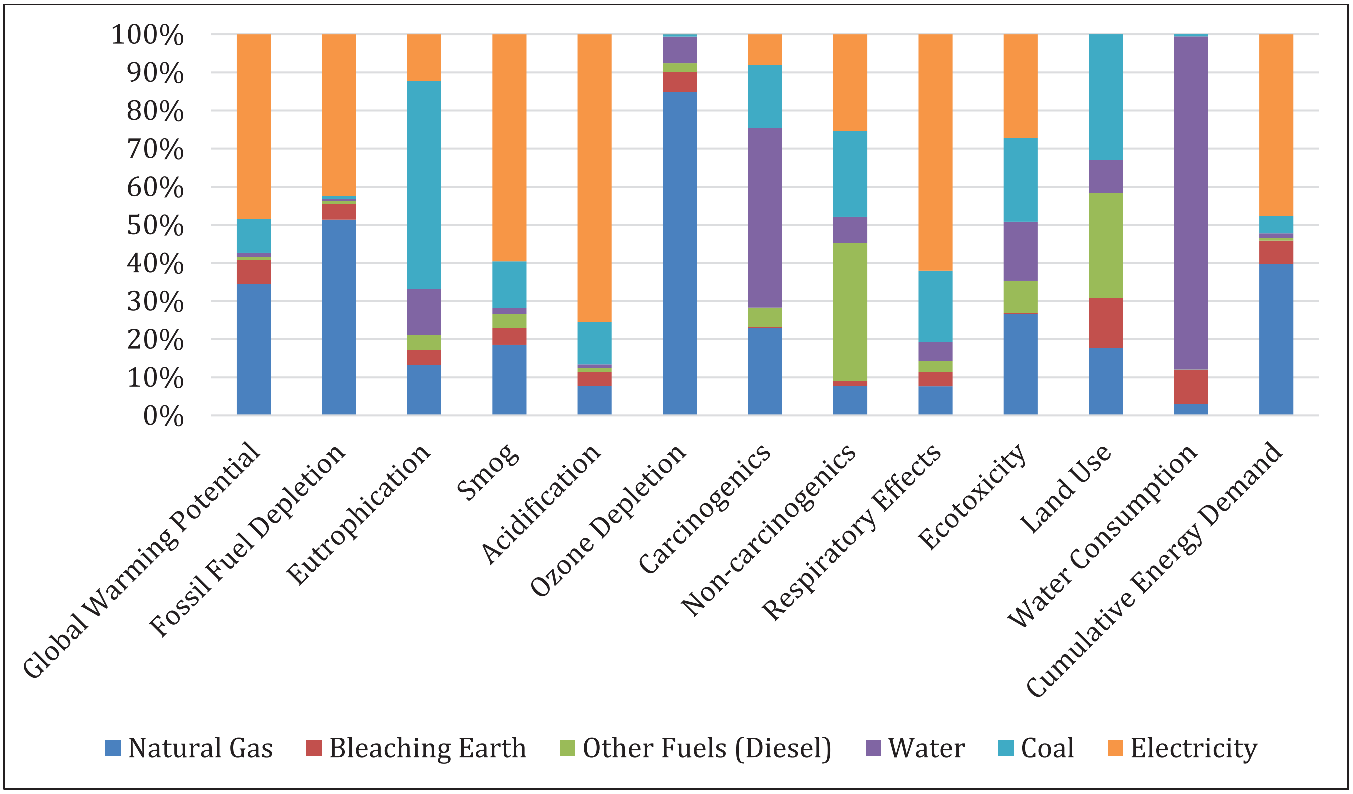

Figure 7.1 – Soy Oil Refining Impacts

Here, natural gas and electricity are the main drivers of most impacts. This is because most of the inputs for refining oil are energy, and natural gas and electricity are the main two sources of energy used for soybean oil refining.

Table 7.2 – Soy Oil Refining Impacts

Impact Category	Unit	Natural Gas	Bleaching Earth	Other Fuels (Diesel)	Water	Coal	Electricity	Total

7.3.2 Overall

The graphs in this section are designed to communicate the overall cradle-to-facility-gate environmental impacts of refined soybean oil. These include soybean agriculture, transportation to oil processing facility, the crushing and degumming process, and soybean oil refining.

Table 7.3 and Figure 7.2 demonstrate the overall environmental impact (using the modified TRACI methodology) of manufacturing one kilogram of refined soybean oil. The figure illustrates the relative impact contribution from each of the life cycle stages (soybean cultivation and harvesting, soybean transportation, the crushing and degumming process, and soy oil refining) to each of the environmental impacts. In this analysis, soybean transportation impacts are separated from the "soybean cultivation and harvesting" stage.

Table 7.3 – Refined Soybean Oil Environmental Impacts using the TRACI Impact Methodology

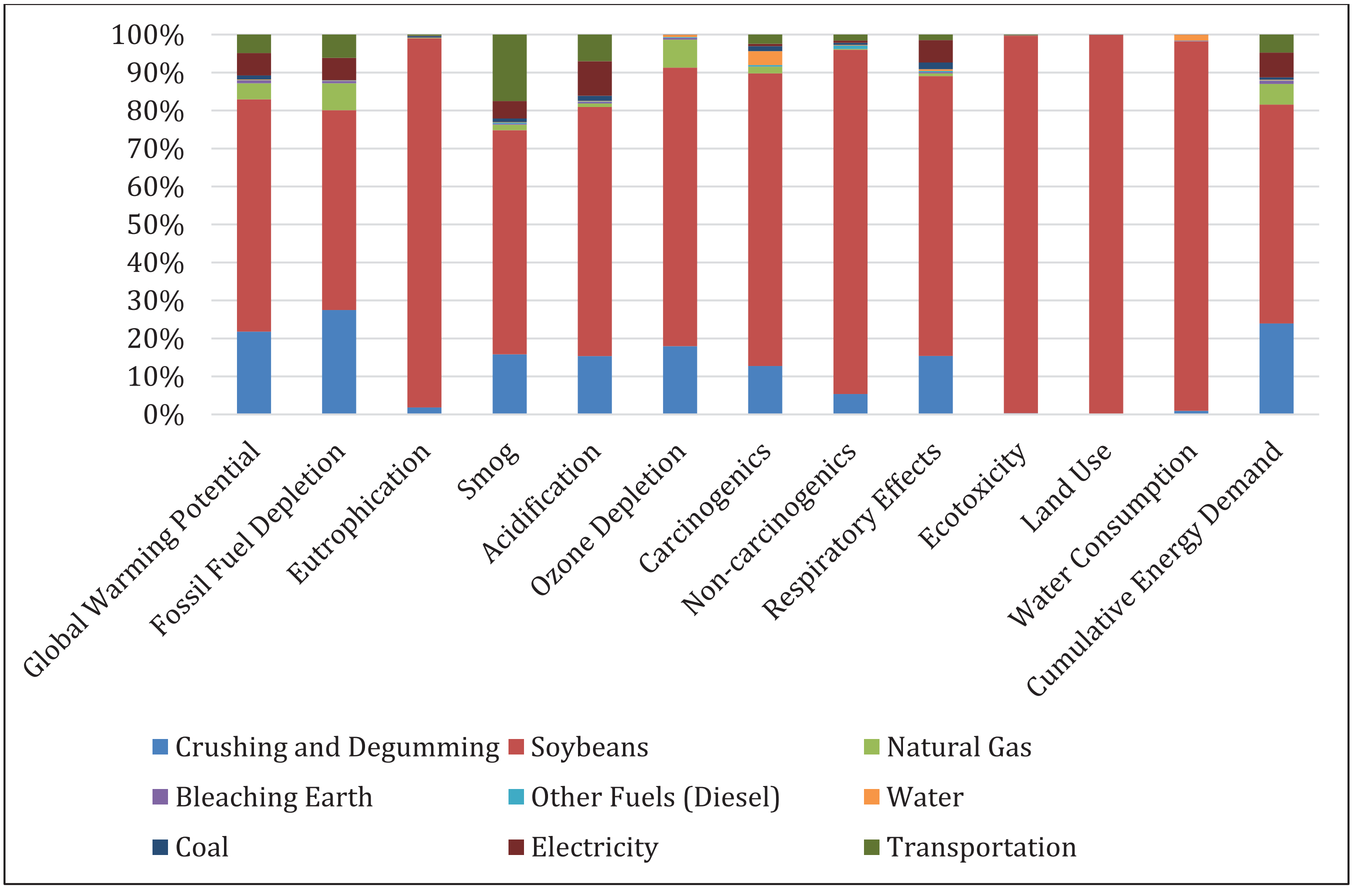

Figure 7.2 – Environmental Impacts of Refined Soybean Oil (TRACI Impact Assessment Methodology)

Overall, soybean cultivation and harvesting is the main driver of environmental impacts, with its contribution ranging from approximately 54% for GWP to almost 100% for land use.

Figure 7.2 shows that, similarly, to results for the crushing and degumming process to produce crude soybean oil, soybeans contribute a majority of the impact in most categories for refined soybean oil. The crushing and degumming process also has a slightly higher impact than oil refining. For eutrophication, human toxicity and ecotoxicity, the majority of the impacts occur also in the soybean agriculture stage, mostly due to the use of fertilizers and crop residue of nitrogen. Overall, environmental impacts of refined soybean oil have also declined overtime when compared to the results from the 2015 study, as shown in Figure A.4 in Appendix A.

8.0 Additional Analysis – Biofuels

Soybeans are 18-20% oil by mass and have fewer nutrient requirements than any other oilseed crop. Consequently, one of the primary uses for soy oil is as a renewable, plant-based feedstock in the production of biodiesel, renewable diesel and sustainable aviation fuel. In fact, U.S. Energy Information Agency data indicate that over 60 percent of U.S. biodiesel today is produced from soy oil.

Biofuels are vital in meeting U.S. transportation needs and climate policy objectives. For example, soy-based biodiesel offers a more sustainable energy source than fossil fuels, and has replaced billions of volumes of petroleum-based diesel under the U.S. Environmental Protection Agency's Renewable Fuels Program. According to the Clean Fuels Alliance America:

- For every unit of fossil energy it takes to produce biodiesel, as much as 3.5 units of renewable energy is returned, the best of any U.S. fuel.
- Compared to petroleum-based diesel, biodiesel lowers particulate matter pollution by 47%.
- Biodiesel combustion emits less greenhouse gases that can contribute toward GWP, compared to petroleum-based diesel, biodiesel can reduce hydrocarbon emissions by nearly 70%.

Increased production to meet market demands may impact water and air quality if facilities are not operated in accordance with environmental permitting requirements, agricultural development for oilseed cultivation in the U.S. may impact biodiversity in certain regions and can result in direct or indirect land use changes.

The effects of utilizing biodiesel, which is largely produced using soy oil feedstocks generated by the soybean processing companies that participated in this study, in different concentrations to replace diesel, gasoline, propane, and natural gas during soybean cultivation are illustrated in Figure 8.1 and detailed in Table 8.1. This sensitivity does not account for energy efficiency differences between the current fuels and biofuels, or practical limitations associated with the complete replacement of traditional petroleum-based fuels with biodiesel.

Table 8.1 – Environmental Impacts of Replacing Fossil Fuels with Biodiesel for Soybean Cultivation/Harvesting

Impact Category	Unit	0% Biodiesel	50% Biodiesel	100% Biodiesel

Cumulative Energy Demand	MJ	4.46E+00	4.22E+00	3.99E+00

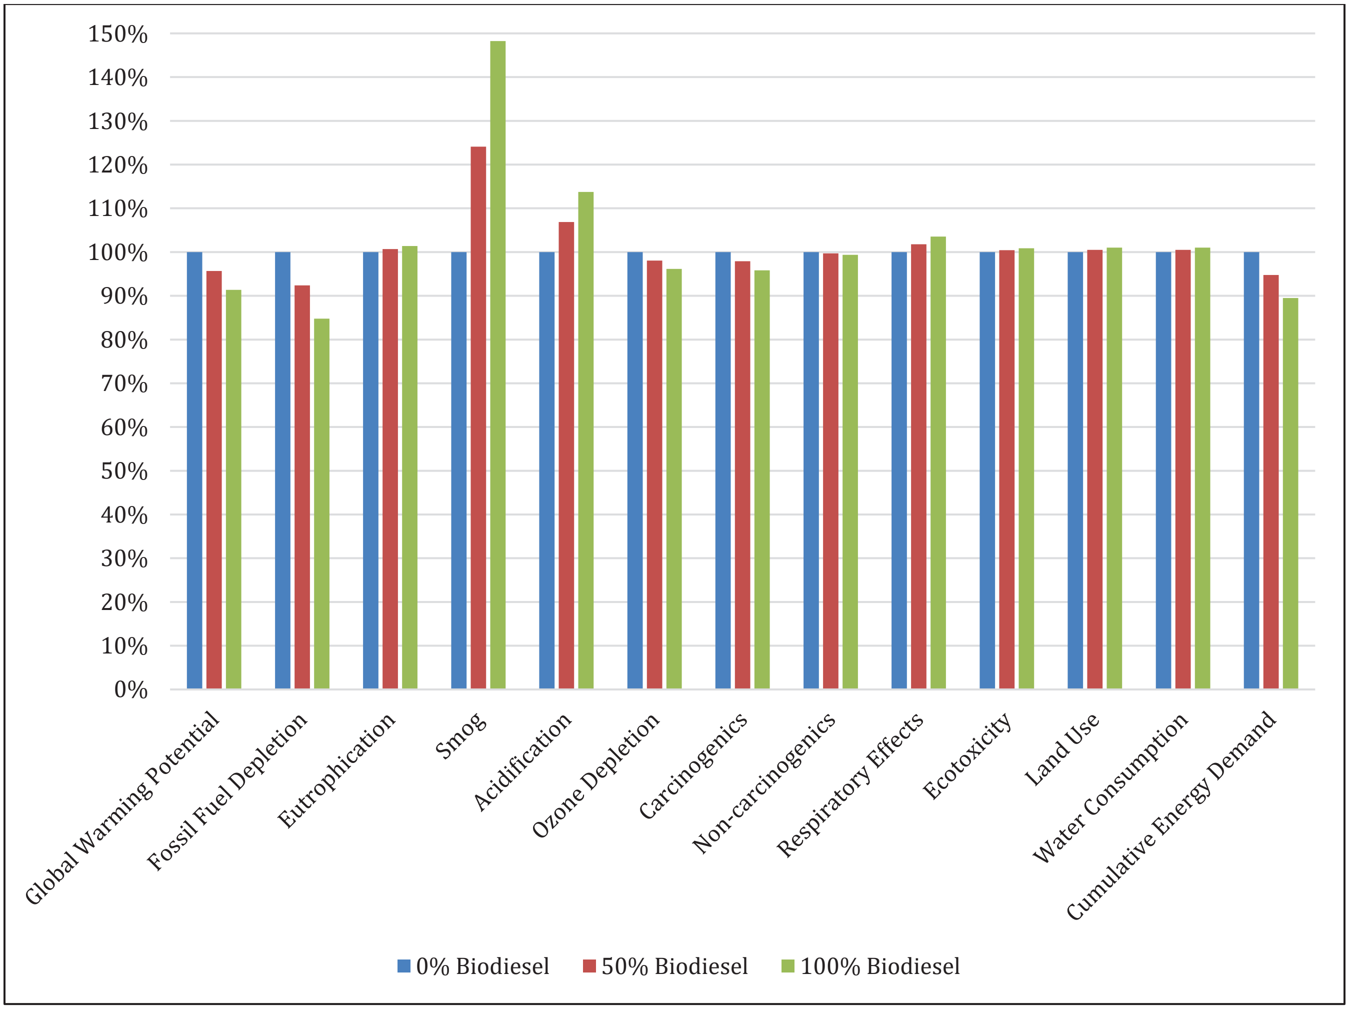

Figure 8.1 – Environmental Impacts of Replacing Fossil Fuels with Biodiesel for Soybean Cultivation/Harvesting

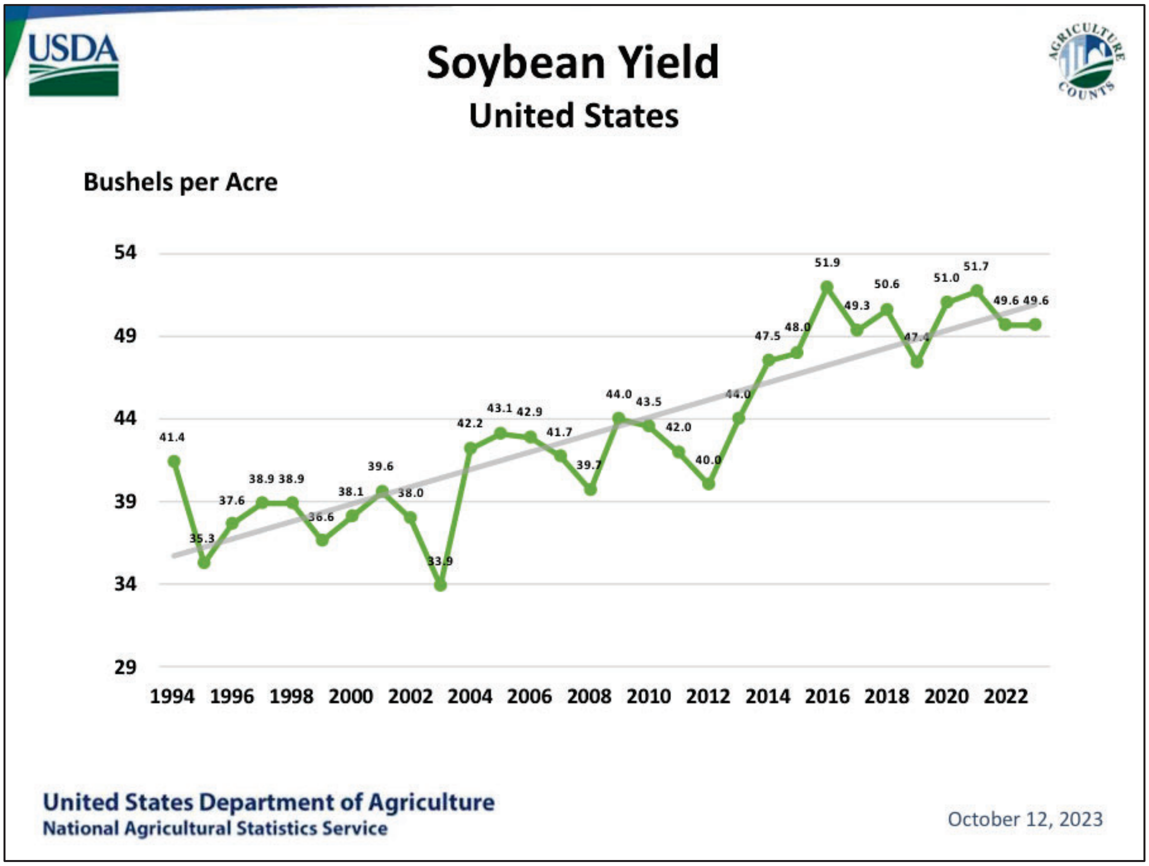
The most significant change is smog, which increases significantly because biodiesel combustion generates more smog than other fuel alternatives. Acidification also shows a visible increase when switching to biodiesel, but on a smaller scale than smog. While biodiesel has higher impact in those two categories, it also remains relatively the same in eutrophication, land use, and water consumption. Switching to biodiesels also shows considerable improvements in global warming potential, fossil fuel depletion, and to a lesser extent, ozone depletion.

9.0 Sensitivity Analysis

9.1 Harvest Yield

The most influential variable in the soybean farming operation was determined to be the harvest yield, characterized as bushels of soybeans per acre of farmed land. Soybean yields (bushels per acres) continue to improve as indicated by the USDA figure below. Improvements in seed quality and farmer practices drive more bushels per acre, as demonstrated by numerous reporting agencies. This is being done while reducing chemicals, passes through the fields, and increasing practices such as no till and cover crop expansion.



The average yield for all soybean farming in the United States is 51 bushels/acre (USDA 2020) which is the value applied to calculate the baseline results of the study. Soybean yields have been reported in the range of 40-70 bushels/acre (USDA 2020, farming survey). Lower yields of around 40 bushels per acre result from the use of organic farming techniques (USDA 2020). Lower yields can also occur under sub-optimal growing conditions (e.g., when crops don't receive sufficient water in drought conditions).

A value of 41 bushels/acre was selected as the low bound for sensitivity analysis. This value is consistent with the yield from the previous LCA carried out by Quantis and is near the lower limit for reported yields as described in the scenarios above. A value of 61 bushels/acre was selected for the upper bound. This value represents the average yield reported in the farming survey and is near the high average of 64 bushels/acre reported for fully irrigated soybean cultivation (USDA 2020). Impact results at the lower and upper bound of the soybean yields show approximately a 25% change over the baseline case. Figure 9.1 and Table 9.1 illustrate the result differences.

Note: This analysis only represents changes in yield data for the 2020-2021 years and not any other parameters that may influence yield, such as fertilizer application.

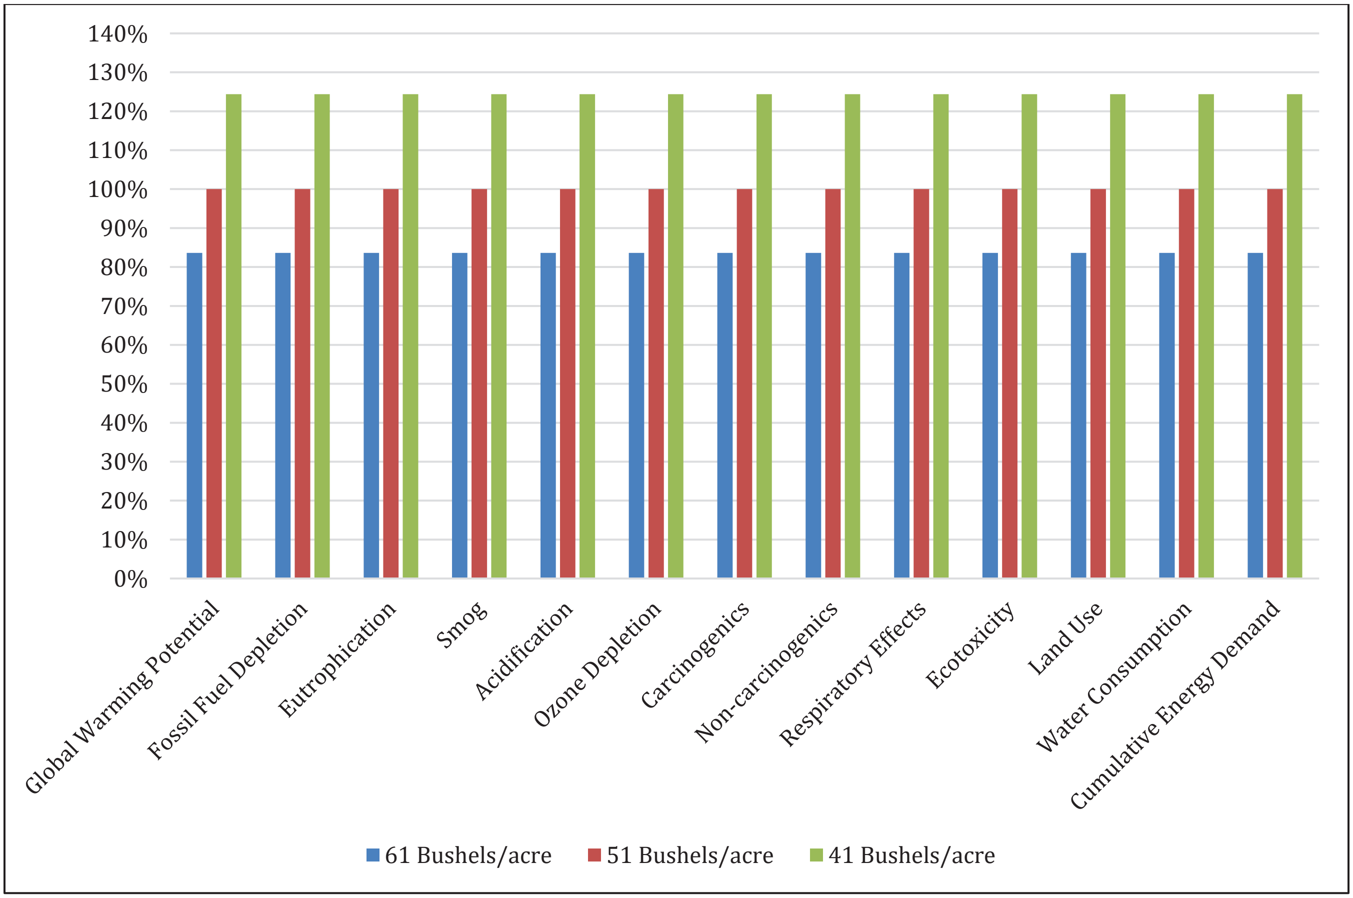


Figure 9.1 – Soybean Yield Sensitivity Analysis

9.2 Diesel

Survey results suggest that farming practices require approximately 1.4 gallons of diesel per acre, which under the current yield assumptions results in approximately 0.001 gallons of diesel per kg of soybeans. However, previous studies had worked under the assumption that soybean farming requires approximately 5 to 6 gallons per acre, which under current yield assumptions corresponds to 0.0036 and 0.0043 gallons per kg, respectively. A sensitivity analysis tests the effects of higher diesel concentrations, comparing baseline survey results to 2.5 gallons per acre, 5 gallons per acre, and 6 gallons per acre. Results are shown Figure 9.2.

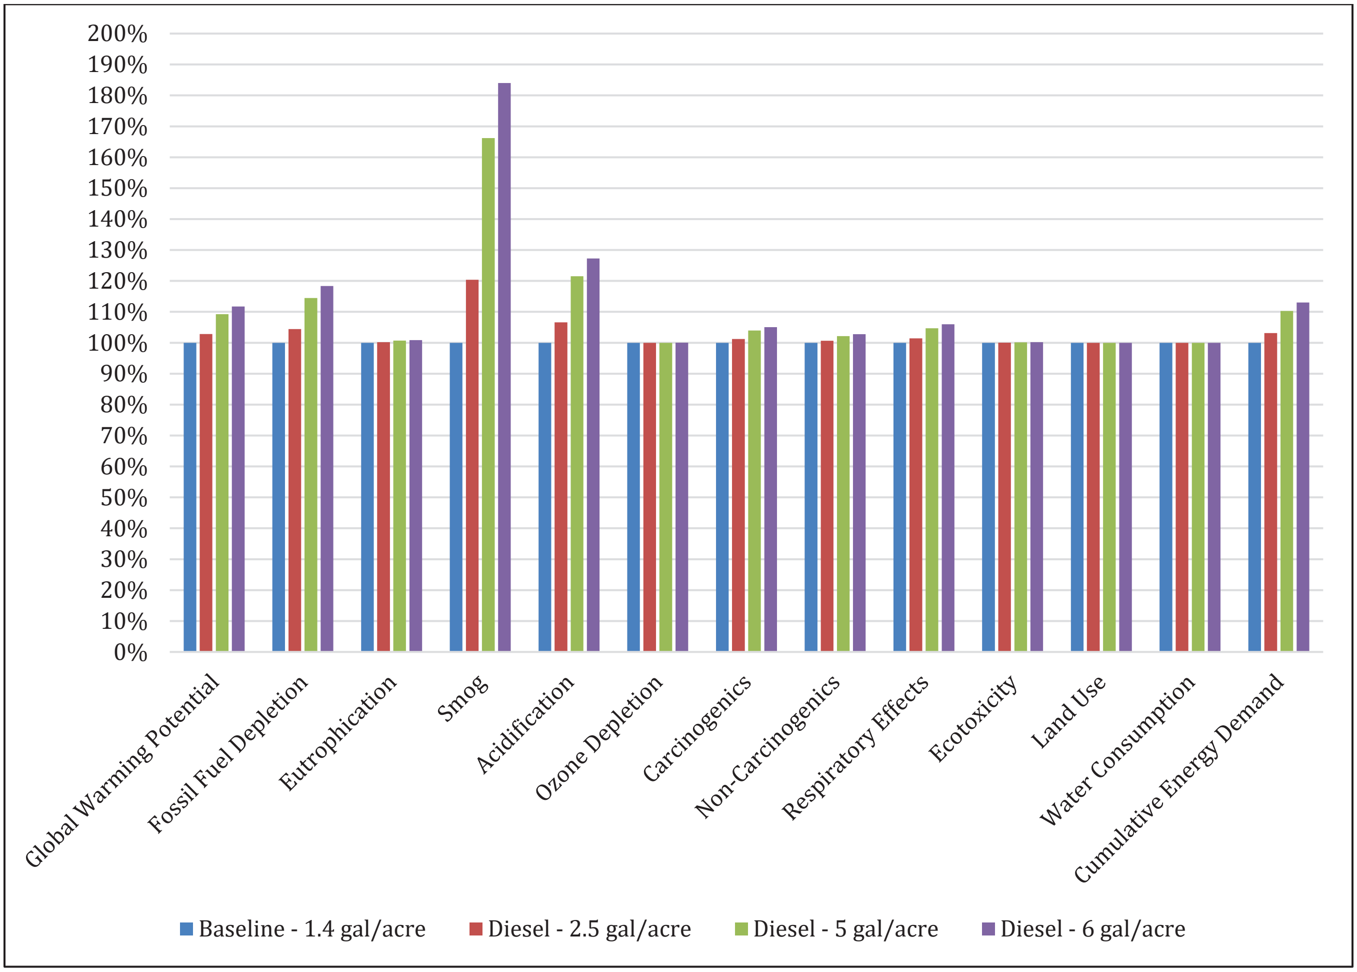

Figure 9.2 – Diesel Sensitivity Analysis, 1 kg of Soybeans

The effects of higher diesel concentrations remain relatively low in most impact categories except smog. This is due to the chemical reactions that take place when diesel is combusted. Overall impacts resulting from each of the different diesel quantities considered in this sensitivity analysis are included in Table 9.1 below.

Table 9.2 – Environmental Impacts of 1 kg of Soybeans with Different Diesel Concentrations

The results are very similar to those for soybeans, with little to no significant change for most impact categories outside of diesel. However, as processing the soybeans or further processing the oil increases processing impacts, this results in lower overall changes when increasing the quantities of diesel used in farming.

9.3 Allocation Methods

Soybean meal and crude soybean oil are co-products during the soybean crushing and degumming stage. Energy and raw materials for this process were allocated to each product based on mass. This is consistent with the allocation method used in the 2015 Quantis LCA study, but other allocation methods, such as economic and by energy content, were also considered. Economic allocation consists of allocating energy and resources to each product based on their economic value in the market. This is a good alternative for allocation when products that would normally be considered waste streams are sold to other markets. This is also the allocation method recommended by EU Product Environmental Footprint Category Rules for Feed for Food Producing Animals. Allocation by energy content allocates materials and resources to each co-product based on their caloric content. This can be helpful when allocating for co-products that will be used to generate energy, such as oil. Figure 9.5 shows what percentage of the environmental impacts of each kg of processed soybeans are allocated to crude soy oil and to soybean meal according to each of the different allocation methods.

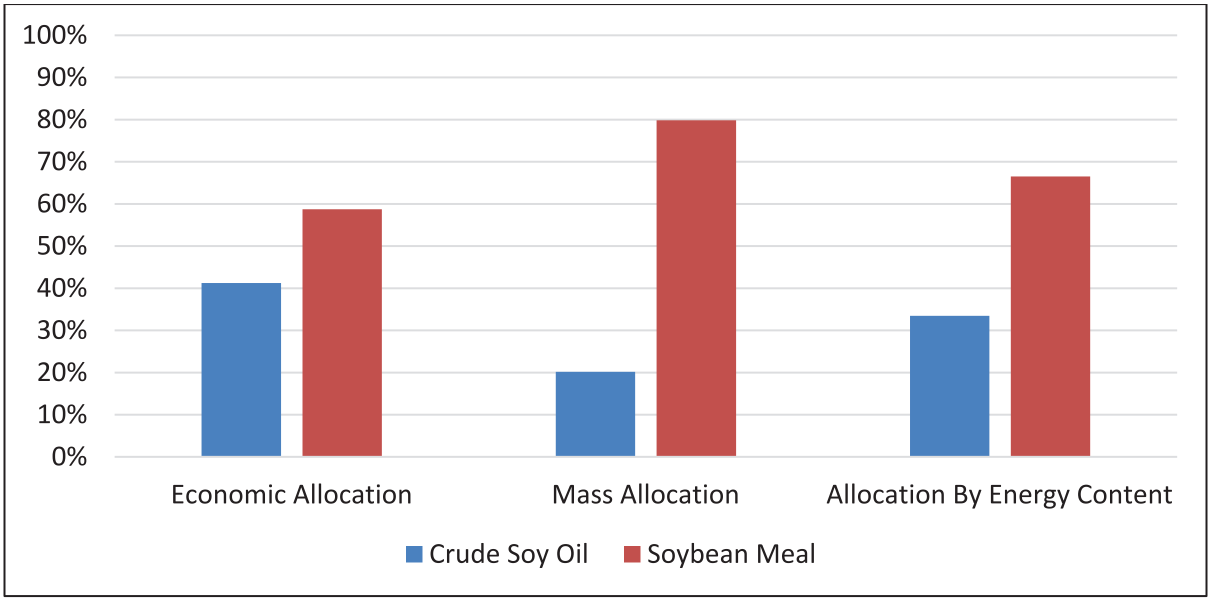

Figure 9.5 – Soybean Allocation Sensitivity Analysis – per kg of Soybeans

Soybeans are approximately 20% oil by mass, and the rest is turned into soymeal. Since soymeal is about 80% of the product, it has a higher allocation of impacts regardless of which method is used. Overall, the gap between their respective shares of impacts decreases with economic and energy content allocations: 20% oil/80% meal for mass allocation, 33% oil/67% meal for allocation by energy content, and 41% oil /59% meal for economic allocation. This happens because crude soy oil has a higher energy content than soybean meal, and it is significantly more expensive. Figure 9.6 portrays what percentage of impacts are allocated to soybean meal in proportion to those allocated to crude soy oil on a per-kilogram of each product basis.

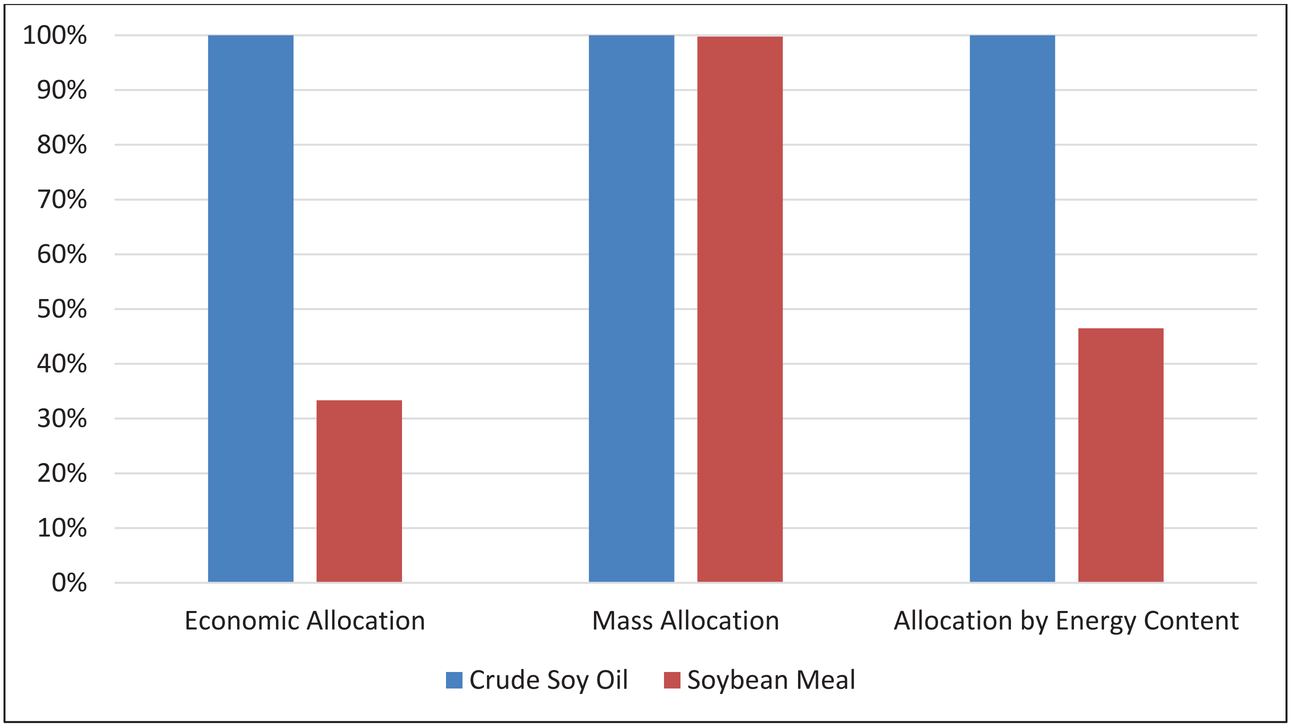

Figure 9.6 – Soybean Allocation Sensitivity Analysis – per kg of Product

10.0 Limitations

All energy and waste data for the soybean cultivation and harvesting were obtained directly from U.S. soybean farmers through collaboration with a third-party survey organization. The data for water usage and soil management practices were obtained from publicly available USDA surveys. Transportation distances and modes were collected directly from publicly available data published by the Soy Transportation Coalition. All processing and transportation data were collected and provided directly from NOPA. Fertilizer data were obtained from USDA. Efforts were made to check the data for internal consistency and to verify data with organization personnel.

The findings in this research are limited by the inherent uncertainty of creating a representative model through LCA. Many assumptions were made in modeling the product system with representative processes and datasets. The authors addressed the uncertainty in modeling decisions by conducting a mass balance and sensitivity analysis as the LCI model was being constructed (data verification/validation relative to cut-off criteria and study goals).

Geography, soil, and rainfall are just some of the key variables that influence soybean cultivation. This study attempts to capture the average case for soybean cultivation in the United States. The results for individual farming practices will differ based on their unique operations. Approaches such as organic farming result in different emissions profiles but may have lower yields, resulting in different impact profiles per unit produced. During the period of this study, organic soybeans represented 0.3% of the entire U.S. soybean production, thus, organic soybeans were excluded from the scope of this study. Additionally, crop rotation is a method commonly used in soybean cultivation to utilize the benefits of soil nutrients leftover from crop cultivation. This study allocated the field operation inventory based on harvest acreage; however, there are more nuances and complexities behind this system that makes this an oversimplified allocation. This was the most feasible way to account for the crop rotations but should be noted as a limitation of the study. While the farming survey is believed to be representative of the average soybean cultivation and harvesting practices, any additional data collection on soybean agricultural activity would strengthen the study. Similarly, yield and field applications are known to have a direct correlation on the environmental impact of agricultural products. A sensitivity analysis was conducted to evaluate how yield would affect the results presented; however, field application rates were not adjusted accordingly due to the complexity of soil nutrient maintenance. This is an opportunity for improvement of the study.

There exists limitation within the secondary data used for the material processes. One of these limitations is the reliance on assumptions, as established in Section 5.1, Section 6.1, and Section 7.1. Another limitation is from the methodology for obtaining primary data. The methodology relied on responses from many different farmers who were not instructed on how to specifically measure the data points. This approach can inherently carry some uncertainty based on the method of measurement. Due to the volume of responses collected, it was not feasible to host individual sessions on how to measure data; however, SSC conducted a thorough screening of the survey responses to eliminate any data points that were inconsistent with traditionally expected ranges. The ideal solution to this limitation would be to employ a single team to go to each survey site and measure the data points of interest using a pre-established methodology. This solution would require a multi-year planning and implementation procedure to collect all the necessary data for a production year, and thus would risk the temporal relevance of the study data. Due to this limitation, the data collection survey was not capable of including fertilizer application rates which have a direct correlation to the yield of production.

Additionally, primary data for this study were based on survey responses from 454 U.S. farmers across 16 states, which might not fully represent the entire soybean industry in the U.S. Attempts were made to expand the field of the survey by inviting 60,000 farmers across all soybean growing states; although, the third-party was unable to obtain responses from the larger sample set in the required timeline. This represents an opportunity for improvement in the study; however, given the temporal and geographic relevance of the data utilized, the study data are still deemed relevant. Similarly, these survey data represent two years of farm practices, but farm practices vary significantly based on numerous factors such as climate, crop rotations, and more. An opportunity for improvement of this study is to utilize three to five years' worth of data in future studies to strengthen the background datasets and mitigate these effects.

The method of data aggregation detailed in Section 6.1 and Section 7.1 present opportunities for improvement of the study in future iterations. Data aggregation based on weight of soybeans processed will eliminate misalignments in the processing mass balance that will improve the results of the study.

An additional opportunity for improvement for this study is the inclusion of soil carbon sequestration in the inventory. This study does not account for soil carbon sequestration due to the complexities of accounting for the carbon mass balance; however, accounting for soil sequestration that results from no-till and cover crop practices, as well as additional agricultural techniques, represents an opportunity to reduce the environmental footprint of the U.S. soybean farming practices.

The EU Product Environmental Footprint Category Rule (PEFCR) and the Global Feed LCI Institute recommend using economic allocation, rather than a mass-based allocation which was used in this study. This is acknowledged as a limitation to the study's applicability to European markets, however, this study is intended for North American markets, so a mass allocation was used to remain consistent with previous studies. Evaluating an economic allocation approach is recommended as an opportunity for improvement in future studies.

A quantitative uncertainty analysis was not conducted as it is only required for statements of comparative assertion per ISO 14044. Only the data quality assessment described in Section 3.0 to evaluate the uncertainty in use of inventory data has been carried out. The characterization models used to calculate midpoint and endpoint results also introduce uncertainty; however, there is currently no way to quantify this uncertainty in the software tools being used. Therefore, the overall uncertainties will be necessarily underestimated due to this uncharacterized uncertainty in the characterization models.

11.0 Conclusions

Soybean yields have trended upwards since 2010, from around an average return of 41 bushels per acre planted to 51 bushels per acre. This 24% increase is the result of improved farming practices that allow for more efficient use of land. As yields continue to increase, the environmental impacts for soybeans and soybean products will look more favorable on a per mass basis.

Based on the analysis and findings presented above, the soybean meal, crude soy oil, and refined soy oil life cycle impacts are strongly driven by the cultivation and harvesting of soybeans. More specifically, field operations, fertilizer, and herbicides. Further increasing yields, decreasing chemical applications, and reducing energy consumption would be the best way to reduce overall environmental impacts.

Higher soybean yields resulted in increased soybean meal and soy oil production during the same period from around 41 bushels/acre in 2010 to 51 bushels/acre in 2021. This 24% increase in production is also tied to increased global demand for U.S. soy-based feedstocks used in the manufacturing of food, feed, biofuels, and industrial products. Despite experiencing increased production, NOPA member companies have implemented numerous improvements to plant operations based on the latest technology available, plant design and U.S. regulatory requirements, which have resulted in overall process improvements between 2010 and present day.

As discussed in Section 3.0 the data used in this LCA was deemed to be as accurate as possible for quantifying a national average; however, there was high uncertainty in primary data as it pertains to the range of variation in survey responses. USB survey responses accounted for 0.45% of the total U.S. soybean production in 2020 and 2021 but were deemed to be a good representation of the U.S. soybean process as the majority of respondents were from the highest producing geographical regions. NOPA data were gathered from 52 (crushing and degumming) facilities and 27 (oil refining) co-located facilities, representing the vast majority of the U.S. soybean processing industry. SSC recommends utilizing three to five years of data in future iterations of this study in order to improve the quality of the data and reduce the uncertainty of primary data.

Based on the analysis and findings presented above, the life cycle impacts are strongly driven by energy inputs (e.g., electricity), transportation (e.g., rail, truck, barge), and raw material inputs (e.g., soybeans). Any opportunity to reduce energy consumption during the manufacturing process, as well as impacts resulting from the transportation of raw materials and final goods, would have a direct reduction in environmental impacts. Implementation costs and permitting restrictions may impact operational costs and consumers.

12.0 Recommendations

This information can prepare USB and NOPA for future sustainable supply chain requirements and can form the basis of marketing literature focused on environmental benefits. This LCA can also assist USB and NOPA members with greenhouse gas modeling and evaluating their own green product claims.

Opportunities to improve the relative impacts of U.S. soybeans, soybean meal, and soy oil production include:

- Enhancing seed quality to improve soybean yields and protein content to maximize value of U.S. soybean products.
- Guiding farmers to adopt sustainable growing practices through implementation of climate-smart technologies.
- Reducing consumption of high-carbon fuels (e.g., coal, petroleum-based diesel, kerosene).
- Modifying equipment and revising operating procedures, where practicable, to improve energy efficiency at processing facilities and refineries.

At this time, SSC recommends the publication of this study and corresponding data for U.S. soybean, soybean meal and soy oil; and for future use by USB and NOPA as the basis for sharing LCA data if market conditions, government requirements, or customers require public release of the data.

Appendix A: Comparison to Previous Study[8]

The analysis presented in this appendix is focused on evaluating the environmental impact differences between the two studies. Impact categories for comparison were limited to what was reported in the 2015 study, so the only impact categories evaluated in this section were TRACI impacts. Data collection and allocation the two studies were similar in respect to methodology. The methodological consistencies between the recent studies were intentionally kept similar where relevant and appropriate to ensure a level of comparability exists between studies. USB and NOPA intend to use this study internally to evaluate the effect of organizational changes that have been implemented geared toward reductions in environmental impacts. The comparison of the results cannot be entirely attributed to the organizational improvements that USB and NOPA have implemented, due to the improvements in LCA datasets and methodologies, as well as the differences in the LCA methods employed by the LCA practitioners; however, the impact of these changes should not be understated and are considered to have a considerable contribution to the comparison.

The main driving factors for each study stayed consistent. In both studies:

- Field operations and chemical application were the main impact drivers for soybean production.
- Soybean cultivation was the main impact driver for the production of soybean meal, crude soy oil, and refined soy oil.

A.1 Soybean Comparison: 2015 and 2021

A comparison of TRACI environmental impacts of soybean agriculture from 2015 and 2021 is illustrated in Figure A.1 below.

[8] The processing data in the 2015 study were collected in 2010 and reevaluated in 2015 with no changes. The 2015 dataset for refined soybean oil leveraged existing databases and publicly available information; including, the Ecoinvent v3 dataset for soybean oil and meal, and the Omnitech 2010 study for soybean processing.

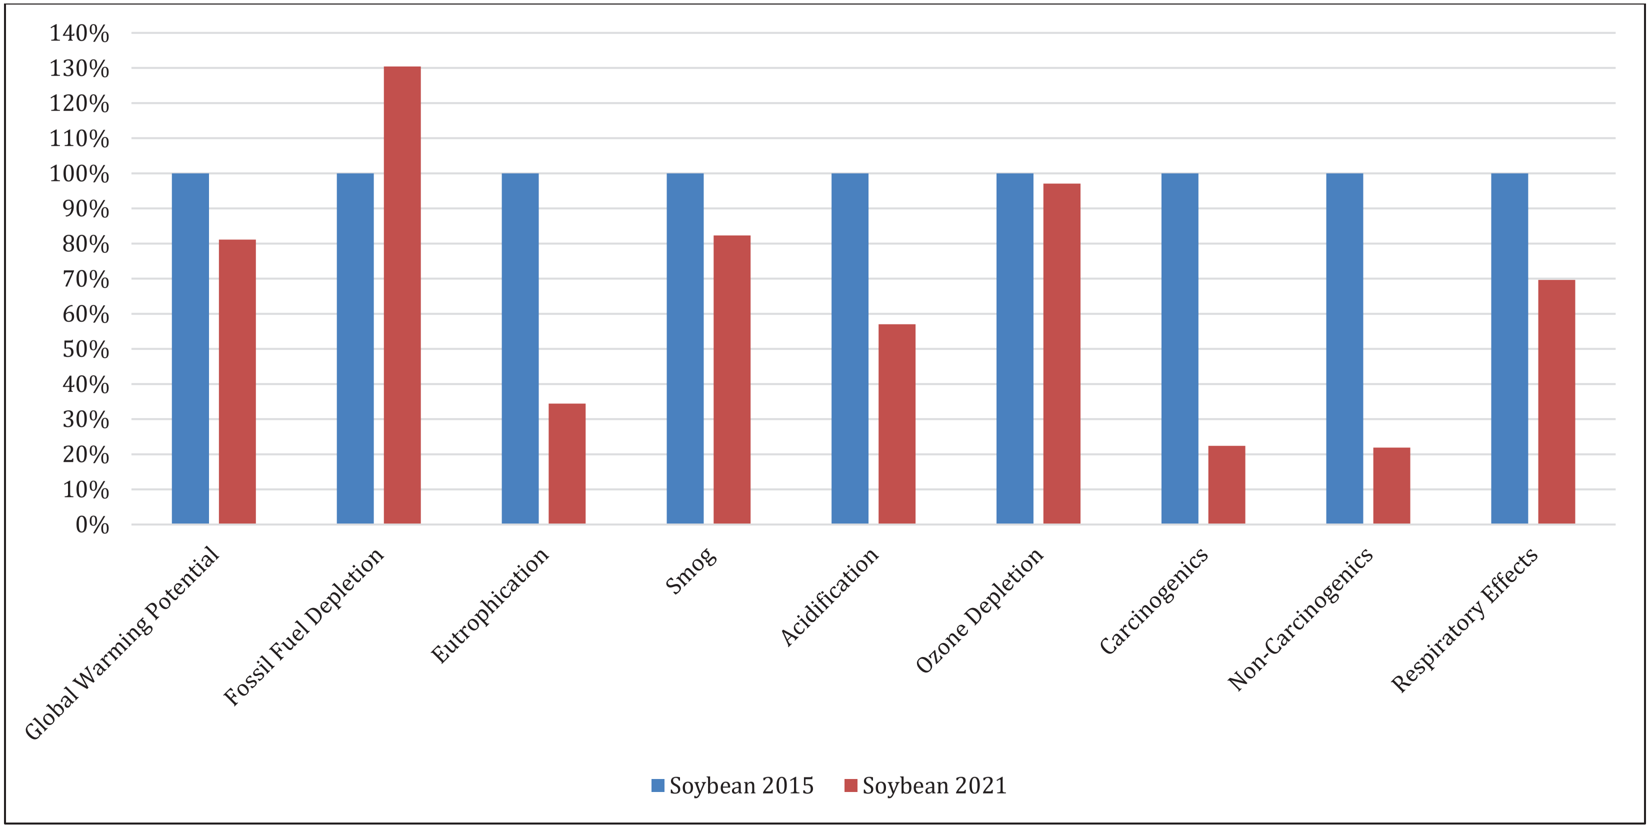

Figure A. 1 – 2021 Values Compared to 2015 Values

The figure above demonstrates that, in general, impacts of soybean production have decreased over the last 5 years. This is due to more efficient farming equipment and farming practices, as well as increasing yields. Yields went from 41 bushels per acre in 2015 to 51 bushels per acre in 2021, which significantly contributed towards impact reduction. Changes in farming practice to use lower impact fuels, such as natural gas, and reduction in pesticide use reduced impacts when compared with the previous study. Overall energy consumption decreased by around 10% per acre, further contributing to the reductions observed. The one exception to this trend is Fossil Fuel Depletion (FFD), in which the impact increased slightly. This is because the use of natural gas for the soybean drying process increased to replace other fossil fuels, such as propane. There are fewer natural gas reserves, which drives FFD up, but since natural gas is a cleaner fossil fuel, it is still better for the environment and reduces overall emissions.

A.2 Soybean Meal and Crude Soy Oil Comparison: 2015 and 2021

The impacts of soybean processing for crude soy oil and soybean meal are illustrated in Figure A.2 and Figure A.3 respectively.

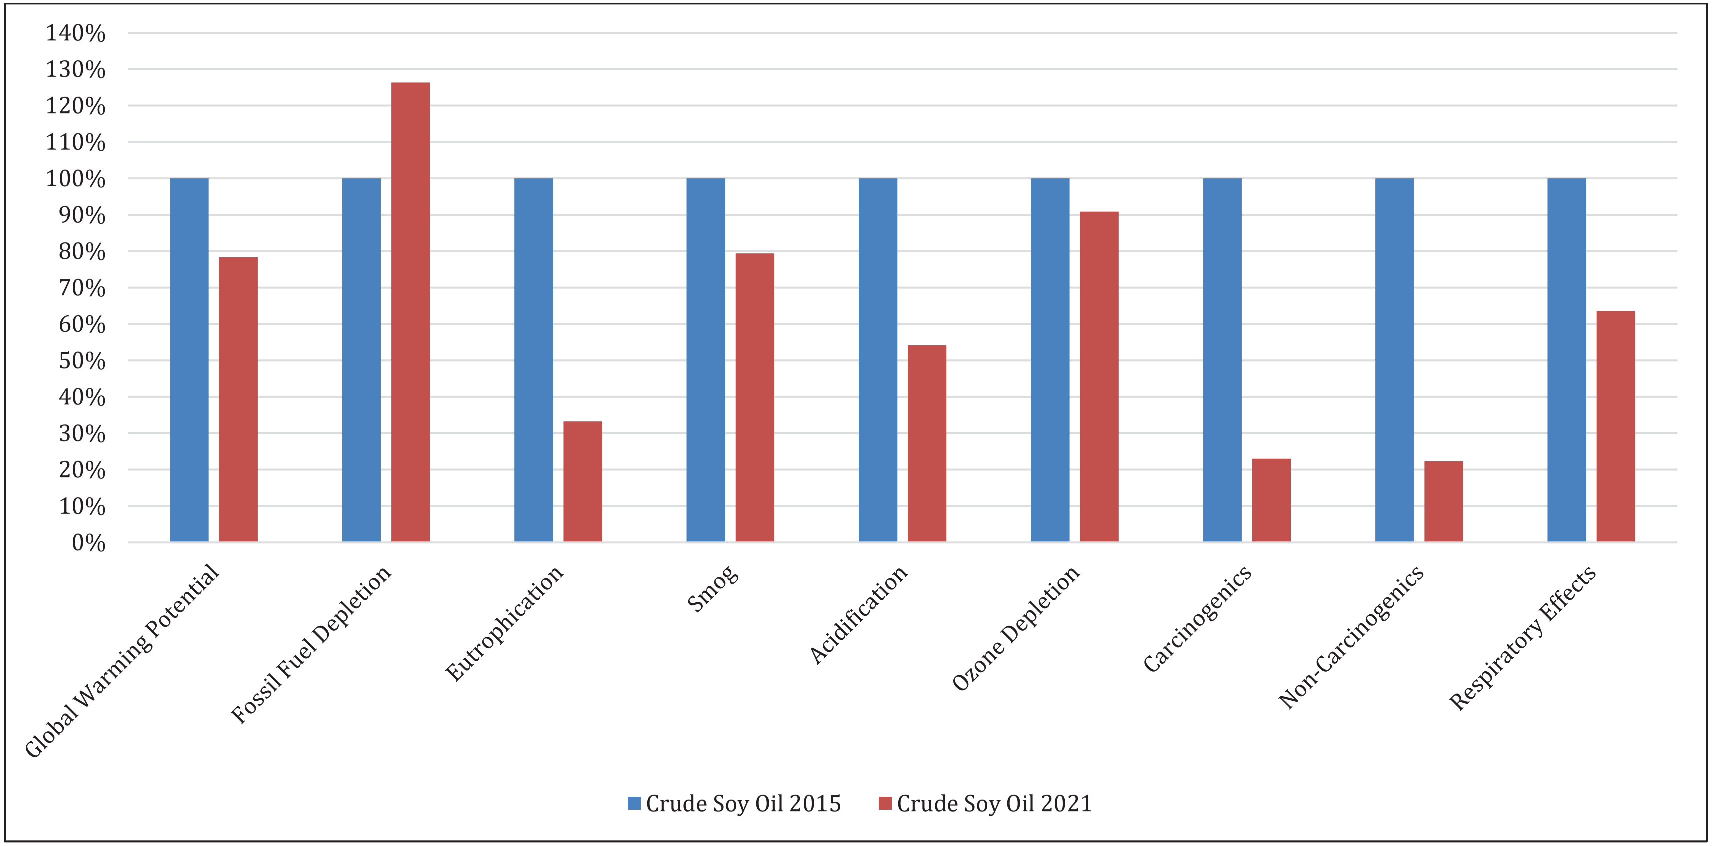

Figure A. 2 – Crude Soy Oil in 2015 vs 2021

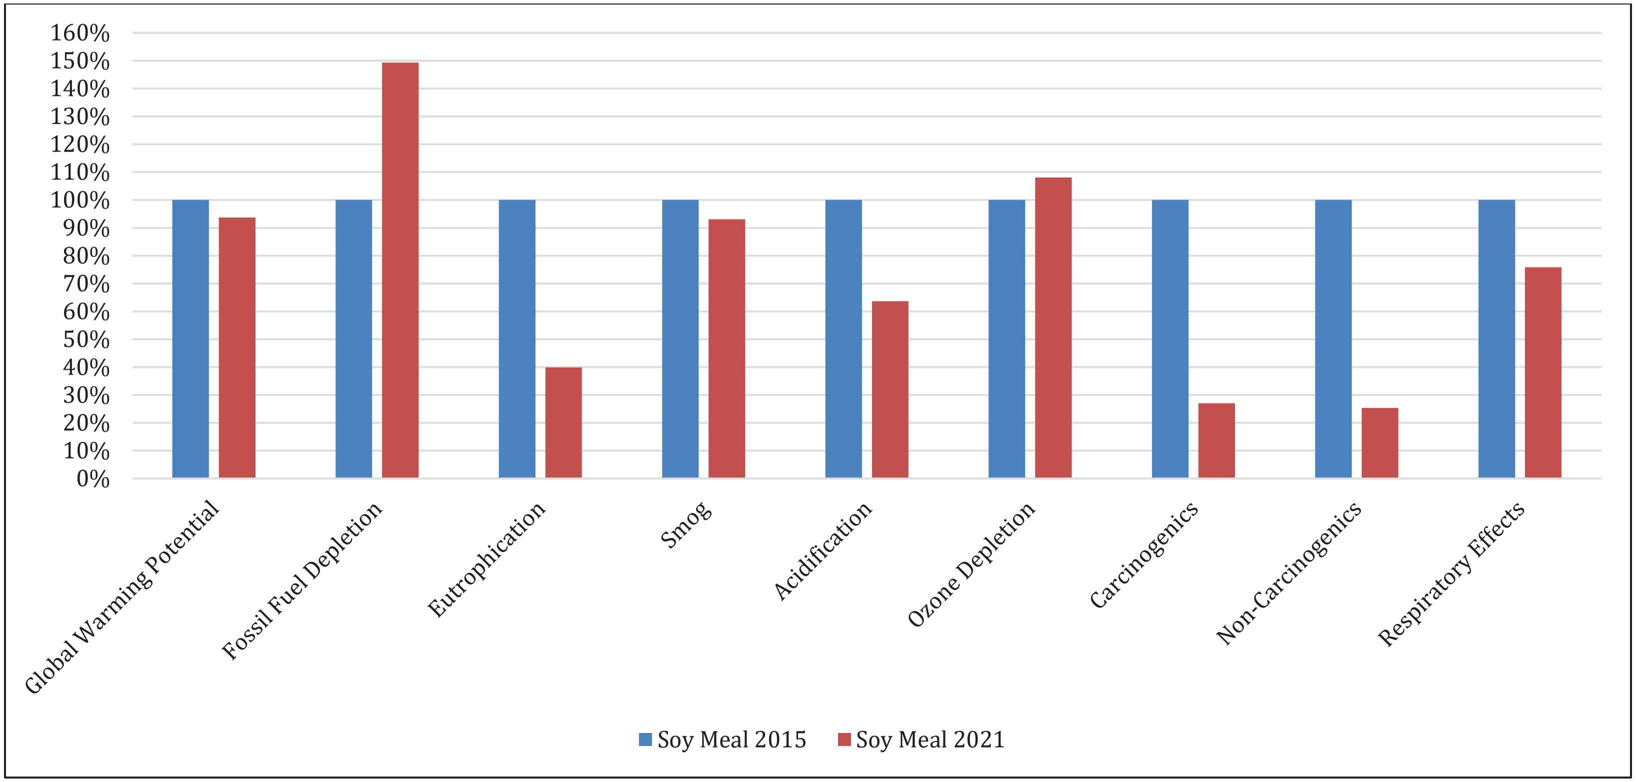

Figure A. 3 – Soybean Meal in 2015 vs 2021

Overall, impacts have decreased throughout most categories, closely following the results from comparing 2015 soybean agriculture to 2021 soybean agriculture. This is partially due to the embodied impacts of the soybeans that have declined over the last several years, and partially because soybean processing technologies have been improving and becoming more efficient. The one exception is fossil fuel depletion, which is a result of the shift to natural gas as a fuel source in farming practices.

A.3 Soy Oil Refining Comparison: 2015 and 2021

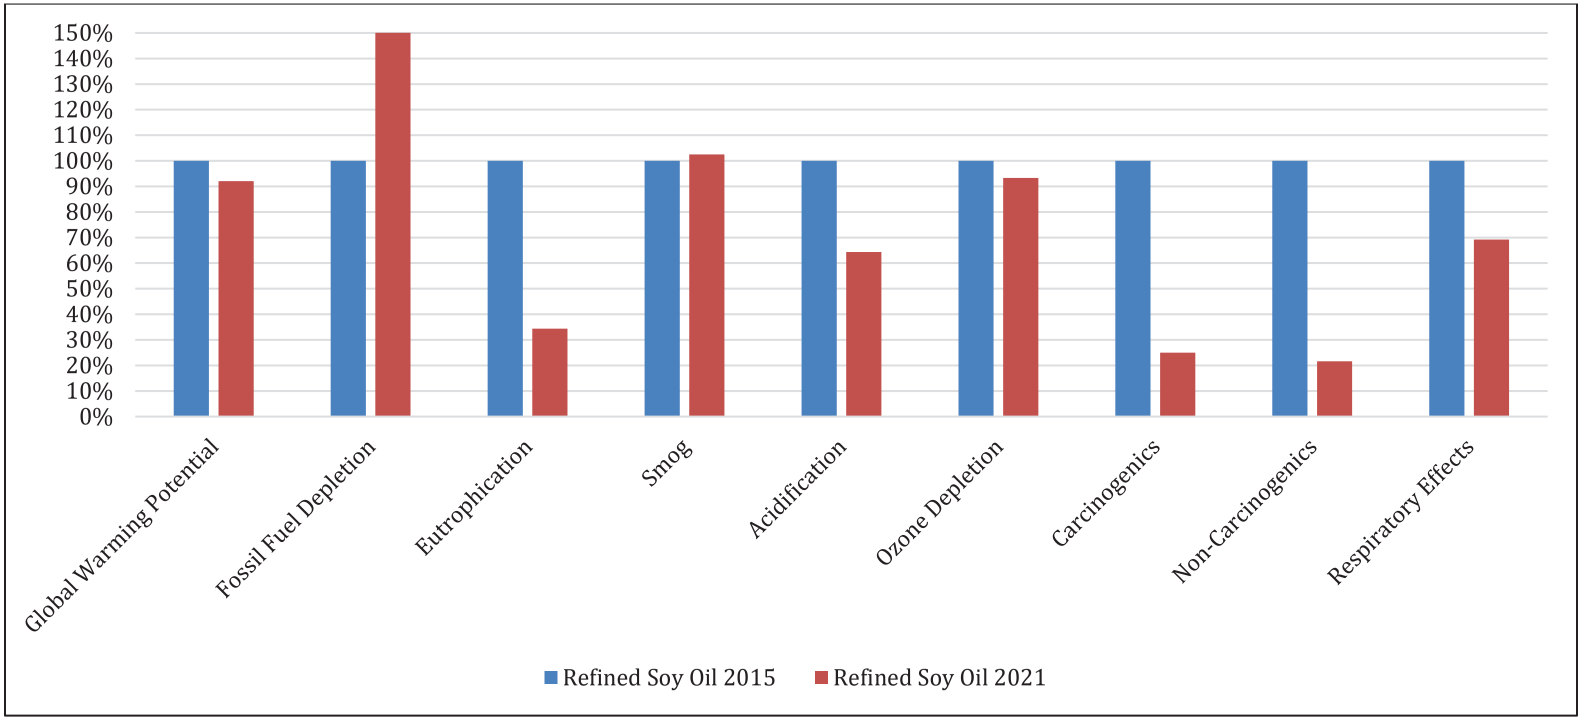

Figure A. 4 – Refined Soy Oil in 2015 vs 2021

Following suit with the soybean product trends described previously, there is a reduction of impacts across the spectrum of impact categories, again with the exception of fossil fuel depletion. The explanation for the previous trends holds true for refined soy oil, since it is downstream of the process flow. In addition, improvements in the refining process contribute to more significant reductions observed in Figure A. 4.

Note: 2015 LCA data was not exclusive to co-located refineries.

Quantified comparative values can be found in Table A. 1.

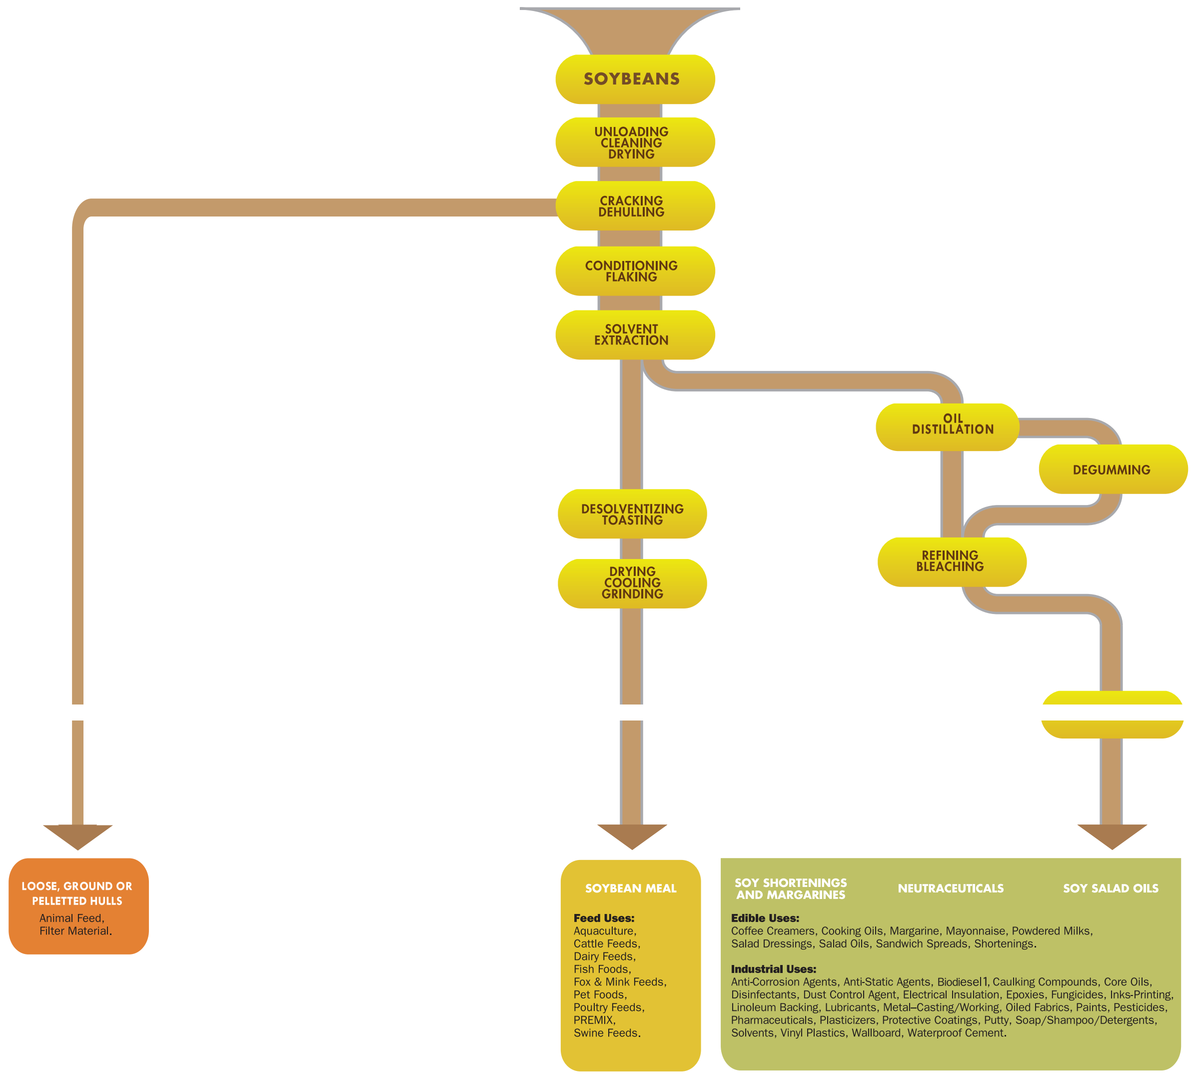
Sodium Hydroxyde	Sodium hydroxide	Inputs from nature	N/A	N/A	N/A	Secondary
Bleaching Earth	Bleaching earth, at plant/RER Mass	Agri-footprint 5	2009	N/A	Bleaching earth production. Dataset was the only available option.	Secondary
Electricity	Electricity, at grid, US/US 2020	USLCI	2020	United States, excluding Alaska and Hawaii	Representative of year 2000 mix of fuels used for utility electricity generation in the U.S. Fuels include coals, fuel oil, nuclear, hydroelectric, and unconventional energy sources. Data are weighted according to percent share of consumption. Includes line loss factor of 9.91%, which represents the difference between electricity generated and electricity sold. SSC modified to represent the average US grid mix in 2020 based on EPA data	Secondary
Natural Gas	Heat, district or industrial, natural gas {GLO}| market group for | Cut-off, U	Ecoinvent 3	2020	Global	The module includes fuel input from high pressure (RER) network, infrastructure (boiler), emissions to air and water, and electricity needed for operation.	Secondary

Component	Input	Database(s) and Source	Temporal Information	Regional Coverage	Technology Coverage	Data Type
Coal	Heat, district or industrial, other than natural gas {RoW}| heat production, at coal coke industrial furnace 1-10MW | Cut-off, U	Ecoinvent 3	2020	Rest of World	Combustion of coke coal in an industrial furnace is modeled based on an combustion of hard coal in an industrial boiler in early 1990s. Stoker boiler used as reference technology.	Secondary
Other Fuels	Diesel, burned in agricultural machinery {GLO}| diesel, burned in agricultural machinery | Cut-off, U	Ecoinvent 3	2020	Global	1 MJ (0.0222 kg) diesel burned for running a tractor with a trailer. The inventory represents heavy road transport with tractor and 2 tyre-trailers of max. 8 t loading capacity each. Mean velocity when loaded = 15 km/h. Mean velocity when empty = 25 km/h. Empty return over the same distance included.	Secondary
Water	Tap water {RoW}| market for | Cut-off, U	Ecoinvent 3	2020	Rest of World	This activity starts from tap water, under pressure, at tap water treatment plant and fed into the tap water distribution network. This activity ends with 1 kg of water at consumer (industrial or household).	Secondary

Appendix C: Soybean Meal and Soybean Oil Process Flow Diagram



NOTE: The National Oilseed Processors Association (NOPA) represents the U.S. soybean, canola, flaxseed, sunflower seed and safflower seed crushing industries. This flowchart is an illustrative diagram of standardized steps employed in the processing of soybeans. The steps employed may vary from plant to plant and from oilseed to oilseed.

Figure C. 1 – Process Flow Diagram for Soybean Processing

Appendix D: Adjusted Crude Soy Oil and Soybean Meal LCI

Table D. 1 - Crude Soy Oil and Soybean Meal LCI Adjusted for 58.6 lbs./bushel

Energy Inputs	Unit	Quantity per kg of Soybean Meal or Crude Soy Oil
Electricity	kWh	3.90E-02
Natural Gas	mmbtu	6.71E-04
Coal	mmbtu	5.55E-05
Biomass	mmbtu	5.18E-06
Other Fuels	mmbtu	8.13E-06
Purchased Steam	mmbtu	5.20E-04
Material Inputs	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Soybeans	kg	1.00E+00
Hexane	kg	5.52E-04
Water	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Inflow	L	3.54E-01
Wastewater	L	1.41E-01
Evaporated Water	L	2.13E-01
Transportation	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Truck	kgkm	7.01E+01
Rail	kgkm	4.69E+01
Barge	kgkm	2.15E+01
Emissions	**Unit**	**Quantity per kg of Soybean Meal or Crude Soy Oil**
Hexane	kg	5.52E-04
Note: Soybean meal and crude oil are co-products resulting from crushing operations. Consequently, inventory data was unable to be allocated to product specific processes and the product values are the same.

Royersford, PA 19468 USA

Enclosure: Review Table

Critical Review Statement: "Life Cycle Assessment of U.S. Soybeans, Soybean Meal, and Soy Oil"

This memo serves as a Review Statement for the critical review of the study performed by Sustainable Solutions Corporation for United Soybean Board and the national Oilseed Processors Association.

The Scope of the Critical Review

As the LCA does not involve a product comparison and will not be used to support a comparative assertion, based on ISO 14044 recommendations, a review by a single external expert was deemed sufficient. The reviewer had the task to assess whether:

- the methods used to carry out the LCA are consistent with ISO 14044:2006 and ISO/TS 14071: 2014
- the methods used to carry out the LCA are scientifically and technically valid,
- the data used are appropriate and reasonable in relation to the goal of the study,
- the interpretations reflect the limitations identified and the goal of the study, and
- the study report is transparent and consistent.

The review of the study was performed to demonstrate conformance with the following standards:

- International Organization for Standardization. (2006). *Environmental management -- Life cycle assessment – Principles and framework* (ISO 14040:2006).
- International Organization for Standardization. (2006). *Environmental management -- Life cycle assessment -- Requirements and guidelines* (ISO 14044:2006).
- International Organization for Standardization. (2014). *Environmental management -- Life cycle assessment -- Critical review processes and reviewer competencies: Additional requirements and guidelines to ISO 14044:2006*. (ISO/TS 14071:2014).

The independent third-party critical review was conducted by Marty Heller, PhD, AgResilience Consulting, LLC

REVIEW SCOPE

The intent of this review was to provide an independent third-party external critical review of a LCA study report in conformance with the aforementioned ISO standards. This review did not include an assessment of the Life Cycle Inventory (LCI) model; however, it did include a critical review of the general approach to complete the study and consideration of the individual datasets applied.

REVIEW PROCESS

The critical review process of the LCA study was conducted to ensure conformance to the International Organization for Standardization (ISO) 14040/44 LCA standards following the review processes and procedures per ISO 14071. The primary task of the review process per ISO 14044 review requirements is to ensure the general requirements for conducting LCA studies are met:

- *Are methods used to carry out the LCA consistent with ISO 14040/14044 standards?*
- *Are methods used to carry out the LCA scientifically and technically valid?*
- *Are data used appropriate and reasonable in relation to the goal of the study?*
- *Do interpretations reflect limitations identified and the goal of the study?*
- *Was the study report transparent and consistent?*

The review process involved the review of all requirements set forth by the applicable ISO standards, cataloged in a comprehensive review table along with editorial comments. There were two rounds of comments by the reviewer submitted to the LCA practitioner. Responses by the LCA practitioner to each issue raised were resolved and acknowledged by the reviewer to have been satisfactorily addressed.
The following summarizes the key comment topics raised by the reviewers that were deemed important for appreciating the nuances and complexities of the study:

- Early rounds of review identified incomplete accounting of nitrous oxide emissions associated with anthropogenic additions of nitrogen to soil. These were sufficiently addressed and updated by the practitioner.
- Primary data used in the LCA were based on a survey of US growers with limited response rate and based on only two years of farm practices. In addition, the survey covered only a portion of the data necessary for the LCA, with the remainder supplemented by USDA statistics, introducing a potential disconnect between the survey population responses and dependent data such as yield. These limitations have been acknowledged in the report.
- The mass allocation method chosen to allocate impacts between co-products of crushing (soybean meal and soybean oil) are not aligned with recommendations from the EU Product Environmental Footprint Category Rule for Feed from Food Producing Animals and the Global Feed LCI Institute. Therefore, care must be taken in making comparisons with results aligned with these international standards. This limitation has been acknowledged in the study.

CRITICAL REVIEW STATEMENT

Based on the independent critical review objectives, the final report, LIFE CYCLE ASSESSMENT OF U.S. SOYBEANS, SOYBEAN MEAL, AND SOYBEAN OIL, dated January 12, 2024, was determined to be in conformance with the applicable ISO standards. The plausibility, quality, and accuracy of the LCA-based data and supporting information are confirmed.

I confirm that I have sufficient scientific knowledge and experience of agricultural processes and the applicable ISO standards to carry out this critical review.

Sincerely,

Marty Heller

Re: Proposed Low Carbon Fuel Standard Amendments

Transportation Fuels Branch Chief Lozo:

Thank you for the opportunity to comment in response to the California Air Resources Board's (CARB) "Proposed Low Carbon Fuel Standard Amendments." The National Oilseed Processors Association (NOPA) appreciates being able to share our observations. NOPA members have a vital interest in these issues.

266.1 **NOPA appreciates CARB's analysis and recognition that consideration of a cap or limitation on crop-based oil feedstocks is unwarranted and would increase fossil diesel use resulting in higher costs for consumers and greater greenhouse gas (GHG), PM2.5 and NOx emissions. CARB should simultaneously promote sustainability and maintain the cost and health benefits afforded by Biomass-Based Diesel (BBD) by**
266.2 **recognizing that fuels certified under the federal Renewable Fuel Standard (RFS) meet CARB's newly proposed sustainability criteria.**

Background

Organized in 1930, NOPA represents the U.S. soybean, canola, flaxseed, safflower seed, and sunflower seed-crushing industries. NOPA's membership includes 15 members that are engaged in the processing of oilseeds for meal and oil that are utilized in the manufacturing of food, feed, renewable fuels, and industrial products. NOPA member companies operate a total of five softseed and 62 solvent extraction plants across 21 states. Collectively, NOPA members process 95 percent of all soybeans in the U.S. which accounts for approximately 2 billion bushels annually.

NOPA members' oilseed processing operations yield protein-rich meal for human and animal nutrition, as well as vegetable oil that is used as an ingredient in food manufacturing and as a feedstock for renewable fuels such as biodiesel, renewable diesel and sustainable aviation fuel (SAF). These sustainably produced biofuels help reduce carbon dioxide equivalent (CO_2e) greenhouse gas emissions and the carbon intensity of transportation fuels in use today. NOPA is uniquely qualified to respond to CARB's proposed sustainability criteria for crop-based biofuels given the number of markets that NOPA members serve, including the food, feed, fuel, and industrial markets.

266.3 NOPA supports California's Low Carbon Fuel Standard (LCFS) which drives demand for biodiesel, renewable diesel and SAF, and encourages investment in low carbon feedstocks and value-added agricultural opportunities. BBD is the largest domestically produced and commercially available fuel to meet the U.S. EPA's definition of an advanced biofuel under the RFS and provides one of the best carbon-reduction strategies for diesel engines available with today's vehicle technologies.

Sustainable Oilseed Processing Feedstocks and Investments

NOPA members are committed to producing sustainable feedstocks. Many of our members have made sustainability commitments and net-zero deforestation pledges. NOPA and the United Soybean Board (USB) published a study which demonstrates the following carbon reductions since 2015:

- 19% decrease for U.S. Soybean cultivation
- 6% decrease for U.S. Soybean Meal production
- 22% decrease for U.S. Crude Soy Oil production
- 8% decreased for U.S. refined soy oil production

NOPA members are also making significant investments to produce sustainable vegetable oil supplies to meet all the demands of biofuel, feed, and food customers. As critical feedstock suppliers to the renewable fuels industry, our industry has announced well over $6 billion in soybean crushing capacity investments since 2021 encompassing some 20 or more expansions or new facilities. These projects are currently on track to increase soybean crush capacity by over 30% between 2023-2026. Collectively, these projects will provide enough additional feedstock to support a 1-billion-gallon increase in BBD capacity over the next several years, **without impacting food or land use**.

This increased capacity will be largely supported by improving the yields from existing acreage already farmed with oilseed crops, increasing the amount of oil produced by such crops and regenerative farming practices, such as cover crops, which reduce the carbon intensity of agricultural practices.

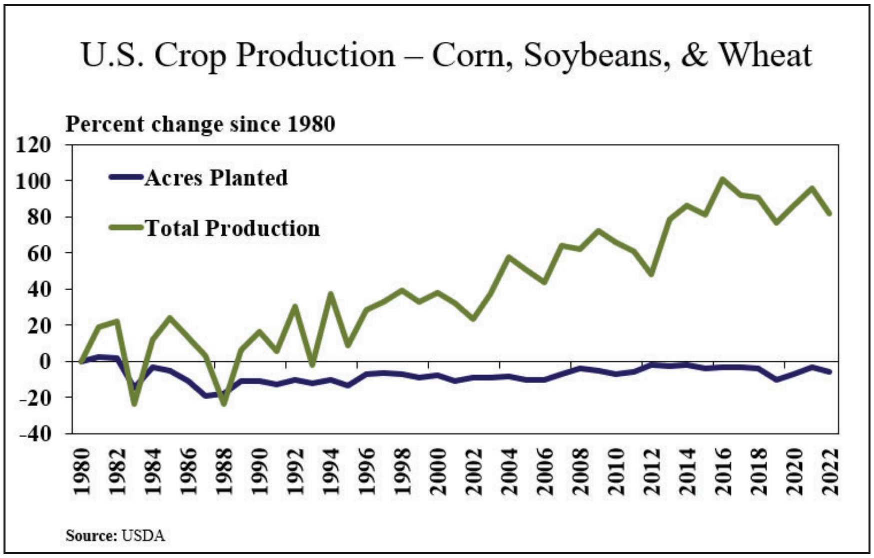
CARB's Proposed Crop-Based Biofuels Sustainability Criteria

266.4 As previously mentioned, NOPA appreciates CARB's analysis and recognition that its previous consideration of a cap or limitation on crop-based oil feedstocks is unwarranted and would increase fossil diesel use resulting in higher costs for consumers and greater GHG, PM2.5 and NOx emissions.

266.5 While CARB's newly proposed sustainability criteria does afford time for market participants to comply, NOPA would urge CARB to adopt a more risk-based approach to addressing deforestation by recognizing the sustainability requirements already provided for under the RFS. By not recognizing that the RFS already requires certification of all the sustainability criteria proposed by CARB, it would have the unintended consequence of disadvantaging regions of crop-based feedstock production with low-risk of deforestation (U.S. and Canada) at the expense of feedstocks produced in regions with a significantly higher risk of deforestation where segregated supply chains are more prevalent due to those risks.

As noted in Figure 1, total U.S. agricultural land use today is lower than it was in 1980; lower than it was when the RFS was created; and lower than it was when the LCFS was created. And total crop production has increased on roughly the same amount of land by over 80%.

Figure 1



266.5 cont. Not only is U.S. agriculture producing more with less and on fewer acres, it continues to do so at the lowest costs due to its comparative advantage in the world through our efficient bulk commodity, aggregation and transportation system. Layering additional cost and segregation on U.S. producers could have the effect of increasing demand for feedstocks from regions with the highest risk of deforestation.

266.6 NOPA also continues to remind CARB staff that it has already overly accounted for land use impacts in the development of the LCFS through the incorporation of indirect land use change penalties (iLUC) – values which continue to be significantly overestimated, and by default provide additional guardrails which CARB staff identified as motivation for additional sustainability criteria.

RFS Compliance with Proposed Sustainability Criteria

266.7 NOPA urges CARB to recognize that fuels produced and certified under the RFS meet CARB's newly proposed sustainability criteria. As demonstrated below, the RFS already meets the sustainability requirements proposed under the LCFS amendments:

Proposed Feedstock Sustainability Requirements	**RFS Feedstock Sustainability Requirements**
Must not be sourced on land forested after Jan. 1, 2008	Must not be sourced from agricultural land cleared or forested after December 19, 2007
Maintain continuous certification	Maintain continuous certification
Certification system must be recognized by an international, national, or state/provincial government for at least 24 months.	The RFS was approved by the U.S. Congress on, and has been in effect since, December 19, 2007
Certification system must consider environmental, social and economic criteria	Factors addressed by U.S. EPA during annual rulemakings to establish Renewable Volume Obligations (RVOs) under the RFS include: • Impact on the environment • Impact on cost to consumers and cost to transport goods, and job creation

266.7 cont.

	• Soil Quality • Environmental Justice
Certification system standard-setting process is participatory, and consensus driven – convening groups of economic, environmental and social stakeholders in both formal and informal manners; and creates a representative steering committee technical working group(s) and advisory group(s)	The passage of the RFS through Congress was by definition consensus driven, which allowed for the input by all stakeholders as afforded during the legislative process. EPA's annual rulemakings to establish RVOs allow for public comment by all stakeholders, both formal and informal. This process includes input from EPA's Clean Air Scientific Advisory Committee (CASAC) – an independent advisory group of non-EPA scientists, engineers, economists and social scientists.
The certification system must have clear, accessible, and transparent processes;	The development of the implementing regulations for the RFS and each subsequent rulemaking to establish RVOs went through a transparent and public comment process before finalization.
The certification system must publish procedures, guidance, certificates and audit report summaries on its website;	All RFS regulations, certificates, and compliance reports are available at https://www.epa.gov/renewable-fuel-standard-program
The certification system must be science based, provide clear targets to reach, and support demonstrable means of evaluation;	The development of the implementing regulations for the RFS and each subsequent rulemaking to establish RVOs by U.S. EPA go through a transparent and public comment process before finalization, based on specific scientific criteria and evaluation.
The certification system must demonstrate that requirements that are additional to the requirements of this sub article are vetted via a multi-stakeholder process to mitigate potential stakeholder bias;	The passage of the RFS through Congress was by definition consensus driven, which allowed for the input by all stakeholders as afforded during the legislative process. EPA's annual rulemakings to establish RVOs also allow for public comment by all stakeholders, both formal and informal. This process includes input from EPA's Clean Air Scientific Advisory Committee (CASAC) – an independent advisory group of non-EPA scientists, engineers, economists and social scientists.
The certification system must maintain an effective auditor training program to ensure auditor competency;	The RFS compliance and audit program is maintained by U.S. EPA and can be found at https://www.epa.gov/renewable-fuel-standard-program/compliance-overview-renewable-fuel-standard-program
The certification system must include an effective grievance mechanism to ensure that problems are resolved;	EPA's annual rulemakings to establish RVOs also allow for public comment by all stakeholders, both formal and informal. A petition process is also afforded under the RFS, which has been utilized by stakeholders. https://www.epa.gov/renewable-fuel-

	standard-program/other-requests-under-renewable-fuel-standard
266.7 cont. The certification system must include sanction mechanisms for participating feedstock suppliers and auditing bodies to ensure conformance with its system requirements; and	The RFS compliance and audit program is maintained by U.S. EPA and can be found at https://www.epa.gov/renewable-fuel-standard-program/compliance-overview-renewable-fuel-standard-program. The RFS and Clean Air Act also establish penalties for non-compliance.

As demonstrated, the RFS already complies with CARB's proposed sustainability criteria and should be explicitly recognized as a compliant certification system under the LCFS amendments.

Ensuring Integrity of Imported Feedstocks

266.8 NOPA notes that imports of Used Cooking Oil (UCO) and other low carbon feedstocks have significantly increased since 2022 for LCFS compliance. While we recognize and support the need for low carbon and waste-based feedstocks, NOPA encourages CARB to undergo additional scrutiny and monitoring of imported feedstocks. Such actions will ensure continued program confidence and compliance.

266.9 **Acknowledgement and Appreciation for Additional CARB Steps on Sustainability Requirements:** NOPA notes that in the amendments to the LCFS, the proposed Sustainability Requirements released on December 19 was the first time stakeholders had any opportunity to review these provisions or its concept. Given the precedent-setting nature of this program in the U.S., and the potential for significant cost and compliance burden to stakeholders, NOPA was pleased to see CARB indicate on February 14 that it will take additional time to allow stakeholders to properly vet the intent, impact, and implications of the proposed sustainability requirements.

Conclusion

266.10 The body of CARB analysis, and market and scientific data collectively demonstrate that consideration of a cap or limitation on crop-based oil feedstocks is unwarranted. Further, doing so at this point would undercut the investments that are being made and are needed for low carbon feedstocks from the industry expansion.

A vibrant U.S. oilseed sector, and the advanced biofuels produced from oilseeds, are critically important to lowering the GHG emissions in the U.S. and California's fuel supply. Efforts to undercut current policies regarding eligible feedstocks will significantly and negatively impact investments being made in lower carbon feedstocks and fuels.

NOPA is eager to continue working with CARB to support the role of agriculture in diversifying the fuel supply through more sustainable feedstocks and thereby supporting cleaner fuel options in California and beyond. On behalf of America's soybean processors, we appreciate this opportunity to comment, and look forward to collaborating with CARB and other relevant stakeholders to enact policies that will address climate change while expanding the use of soy-based biofuels and market opportunities for soybean farmers.

Sincerely,

Kailee Tkacz Buller

Re: Weave Grid, Inc. Comments in Response to Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph, Honorable Board Members, and California Air Resources Board Staff,

Weave Grid, Inc. (WeaveGrid) respectfully submits these comments in response to the California Air Resources Board (CARB) Proposed Low Carbon Fuel Standard (LCFS) Amendments.

I. Introduction

WeaveGrid is a California-based software company that helps load-serving entities support increased adoption of electric vehicles (EVs) through greater understanding of customer charging behaviors, managed charging programs, and distribution-level optimization. WeaveGrid's technology leverages utility and charging data, including the embedded vehicle telematics—data, controls, and communication systems—and the charging equipment to transform unpredictable and disaggregated EV charging loads into a cohesive network of controllable grid resources. We also support load-serving entities in engaging their EV customers with personalized messages, insights, and notifications via the web, email, and text. Our approach enables broad participation in EV load management programs, while helping reduce the costs to serve EV loads. WeaveGrid is a market leader in providing these solutions.

II. Comments

WeaveGrid appreciates Staff's thoughtfulness with the proposed changes to the LCFS regulation. LCFS plays an essential role in supporting California's ambitious transportation electrification goals. WeaveGrid's comments focus on our support for proposed changes to the regulation specific to holdback credits. We also recommend updated guidance for reporting incremental credits for residential EV charging. Overall, WeaveGrid is highly supportive of the efforts to increase the stringency of the program.

A. Strong support for broader use of holdback credits

267.1 WeaveGrid urges flexibility with the use of holdback credits. The transportation electrification sector is rapidly changing, which is encouraging. LCFS serves as an important source of funding in California to advance electric mobility. As needs evolve with the changing sector, a flexible use of LCFS holdback funds can maximize impact.

WeaveGrid particularly supports the proposed additions within Section 95483(c)(1)(A)5.b.[1] As EV adoption in California increases, we need to adapt the grid accordingly. We appreciate that the focus of these proposed additional allowable holdback projects supports greater grid investment to accommodate a growing number of EVs on California's roads. We support the additions in this section, including investments in distribution infrastructure for EV charging, support for vehicle-grid integration (VGI) projects, and technology, such as EV load management software, that can avoid or reduce grid upgrades. Distribution grid investments ensure that charging infrastructure needs are met, especially in underserved communities and for medium- and heavy-duty electric vehicles. VGI projects help EV drivers charge when and where it is most beneficial for the grid and for customers generally.[2] VGI enables cleaner charging by increasing renewables integration and providing a signal for drivers when it is cleanest to charge. Technology helps enable VGI and makes it more driver-friendly by being more automated. VGI projects that use automated technology can benefit from greater participation and, therefore, better outcomes.

B. Recommend updated guidance for reporting incremental credits for residential EV charging

We understand that after LCFS rulemaking updates, there can be updates to associated guidance documents. As such, we are using this comment opportunity to suggest an update
267.2 to LCFS Guidance 19-03. Specifically, for Method 2, Option 1, we recommend that the minimum Geofencing Radius (GFR) be reduced from 220 meters.[3] On-vehicle telemetry has advanced in recent years and particularly the component of telematics specific to identifying geographical location can be very accurate. The current GFR can be very

limiting for measuring incremental credits in densely populated areas where non-residential charging is prevalent, for example, in San Francisco. This update to the guidance can help various entities be further incentivized to provide and use cleaner charging.

III. Conclusion

WeaveGrid appreciates the opportunity to submit these comments. We thank CARB for consideration of these comments and look forward to continued engagement.

Respectfully submitted,

/s/ Amanda Myers Wisser

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Aera Energy Comments on Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Ms. Sahota,

Aera Energy LLC (Aera) appreciates the opportunity to provide the comments below regarding the California Air Resources Board's (CARB) proposed amendments and related 45-day rulemaking documents for the Low Carbon Fuel Standard (LCFS) program. Aera is one of California's largest oil producers, with assets across the State. As a California-based company, Aera understands the need to reduce GHG emissions to work towards the 2045 carbon neutrality target, which is why we are helping lead the State in developing low carbon projects, including carbon capture and sequestration (CCS), direct air capture (DAC), and renewable energy.

268.1 **Section 95489(c)(1)(F). Updates to the Emission Factor for Calculating Credits for Producing Crude Oil with Innovative Methods using Solar or Wind-Based Electricity**

In Section 95489(c)(1)(F), CARB staff propose updating the emission factor for producing crude oil with solar or wind electricity from 511 gCO2e/kWh (current emission factor) to 314 gCO2e/kWh (proposed emission factor), which would result in a 39% reduction in credits generated by these projects. In *Appendix E: Purpose and Rationale for Low Carbon Fuel Standards Amendments*, the rationale for this update is that the solar projects approved by CARB under this pathway to date have been supplemented by grid electricity. Therefore, the avoided emissions from solar projects should be based on the carbon intensity of grid electricity (the proposed emission factor) rather than the carbon intensity of electricity from a natural gas fired combined cycle plant (the current emission factor).

However, this change presumes that future innovative crude solar or wind project applications will all be supplemented by grid electricity, similar to previous project applications. In fact, Aera has contracted with a solar developer to install 37 MW DC (27 MW AC) of solar PV at its Belridge oilfield, with an estimated completion date of 2025. This would be one of the largest innovative crude solar projects to date, and unlike previous projects, the solar electricity would be supplemented with electricity from natural gas fired cogeneration units that currently supply almost all of the electricity to the Belridge oilfield. Therefore, the emissions avoided from this project would be similar to the emission factor in the current LCFS regulation, rather than the proposed reduced emission factor. Lowering the emission factor and credits generated by a project such as the one at Belridge would incorrectly calculate avoided emissions and discourage investment in oilfield solar electricity and energy storage, as companies such as Aera consider installation of much larger solar projects. Aera recommends that innovative crude solar or wind electricity projects that displace natural gas electricity generation utilize the current emission factor when calculating LCFS credits generated.

Section 95489(c)(5). Phaseout Provisions for Petroleum Projects.

268.2 In Section 95489(c)(5), CARB staff proposes to phase out crediting of innovative crude projects no later than December 31, 2040, excluding CCS projects. In *Appendix E: Purpose and Rationale for Low Carbon Fuel Standards Amendments*, the rationale for this phase out was the 2022 Scoping Plan, where the "*State has identified the need to phase down fossil fuel production as fossil fuel demand drops, and the need for all viable tools such as CCS and direct air capture to address the existential threat that climate change presents.*"

While fossil fuel demand in California will decline over time, it is not expected to be eliminated in 2040. Given this need past 2040, as well as the goals of reducing GHG emissions, Aera is evaluating solar electricity and solar steam projects that would be some of the largest in the world, to achieve near-zero emissions crude oil production, including after 2040. This would allow fossil fuel production in California to be much less carbon intensive than fossil fuel imported from elsewhere. Given the size of these projects, they would require years of permitting and construction and hundreds of millions of dollars in investment, with long payouts. Eliminating LCFS credit generation "no later than December 31, 2040" would hurt the investment case for these projects, as well as send a signal to developers of all types of projects that LCFS credit generation could be prematurely eliminated in future rulemaking. Such a phase out, and uncertainty over future potential LCFS regulatory changes, would discourage investment, incentivizing higher emissions from the crude oil producers and imports in the coming years.

In *Appendix E: Purpose and Rationale for Low Carbon Fuel Standards Amendments*, CARB staff also recognize the need for tools such as CCS and direct air capture to address climate change, which is presumably the rationale for allowing these credit generation pathways to continue post 2040. Similar to CCS and DAC, other innovative crude projects such as solar electricity and solar steam are tools needed to address climate change long-term, with the potential to provide zero-carbon energy long after the cessation of oil production. Aera recommends removing the post-2040 phase of innovative crude crediting, supporting investments that not only result in near-term emissions reductions, but also long-term low-carbon energy generation that would benefit the State for decades to come.

Aera looks forward to working with CARB and other stakeholders to craft policies that will facilitate the projects and technologies needed for California's energy transition. If you have any questions regarding this submittal, please contact me via email at rwhoyle@aeraenergy.com.

Sincerely,

Randy Hoyle
Chief Carbon Solutions Officer
Aera Energy LLC

Re: Comments on Proposed Changes to LCFS, Initial Statement of Reasons

The American Soybean Association (ASA) appreciates the opportunity to provide comments on the proposed changes to the Low Carbon Fuel Standard (LCFS) presented in the Initial Statement of Reasons on December 19, 2023. ASA has welcomed the opportunity to engage with the California Air Resources Board (CARB) throughout the LCFS workshop and rulemaking process.

ASA represents approximately 500,000 U.S. soybean farmers on domestic and international policy issues important to the soybean industry and has 26 affiliated state associations representing 30 soybean-producing states. U.S. soybean growers have long been committed to producing the world's food, feed, fuel, and thousands of bioproducts in a sustainable and climate-smart way.

The growth in the biomass-based diesel industry has been spurred by strong federal and state-level policies that promote cleaner, lower-carbon energy sources. Increased utilization of biomass-based diesel over the past several years has had a marked impact on the rural economy. Further, according to CARB's Initial Statement of Reasons, biodiesel and renewable diesel are the largest renewable fuel source and have served as the greatest source of greenhouse gas (GHG) reductions in the LCFS to-date.

U.S. soybean growers have been long supporters and partners in the development of cleaner, lower-carbon fuels. A vibrant soybean sector, and the biofuels produced from soybeans, is critically important to lowering GHG emissions in the U.S. and supporting California's future carbon intensity reduction targets. Importantly, ASA appreciates that CARB has acknowledged the important role of agriculture in the LCFS and has not moved forward with a proposal to cap crop-based feedstocks in this update.

Carbon Intensity Reduction Targets and Modeling Considerations

269.1 ASA is largely supportive of CARB's proposed carbon intensity (CI) reduction targets through 2030 and the auto-acceleration mechanism. However, ASA is concerned that without a comprehensive update to the Global Trade Analysis Project model for biofuels (GTAP-BIO) that CARB utilizes, soy-based feedstocks will be phased out of the LCFS, even though current data indicates a much lower CI score. Without
269.2 updated methodology, soy-based biofuels will only generate credits until approximately 2035, and even sooner if the auto-acceleration mechanism triggers. Updated methodology indicates credit generation for years beyond that timeframe.

During this rulemaking, CARB is updating all major models used for lifecycle emissions calculations <u>except</u> for GTAP-BIO. Rather, CARB continues to rely on a 2014 model that uses data from 2004. As ASA has highlighted in previous comments to CARB, outdated indirect land use change (ILUC) modeling puts soy at a significant disadvantage even though the industry has made vast improvements in sustainability and efficiency over the past two decades. The ILUC score accounts for half or more of the CI score for soy-based biofuels. CARB's current modeling assigns soy biomass-based diesel with an ILUC impact of 29.1g CO2e/MJ whereas updated results from the model used to calculate ILUC scores indicate a value of between 9 and 10 gCO2e/MJ for soybeans[1]. The LCFS is intended to be a science-based program, so using data from 2004 that is no longer relevant undercuts the science and thereby does not incentivize the optimal allocation of feedstocks to decrease carbon emissions.

ASA strongly urges CARB to use the time afforded by a postponement in the March Board public hearing to appropriately update its GTAP model to align with other modeling changes being made. It is incongruous to update more recent models while leaving the older, more impactful model unchanged. The benefits of an LCFS are only achieved if CI values are accurately captured.

Alternative Jet Fuel

269.3 ASA applauds CARB's desire to add intrastate flights to the LCFS program. Leaving some forms of transportation out of the program while leaving others in has financially incentivized switching to the unobligated modes. The proposal would help put air travel and ground travel on the same playing field. We also believe that it could help spur the adoption of new technologies to reduce air emissions such as sustainable aviation fuel.

Sustainability Guardrails for Crop-Based Biofuels

269.4 ASA has significant concerns with the introduction of the sustainability guardrail concept in this proposed rule. While ASA engaged with CARB throughout the informal rulemaking and workshop process, this concept was never discussed publicly as a potential addition to the LCFS program. Any new requirements to develop traceability and certification mechanisms for crop-based feedstocks should be carefully considered with appropriate stakeholder input to avoid potential financial burdens and duplication of current procedures. We find the desire to include the sustainability guardrails especially puzzling given that CARB is not proposing to update the portion of the modeling work that deals with this issue (GTAP-BIO).

If CARB pursues this concept, it is important to consider current sustainability measures that may align with CARB's goals. The U.S. does not have a deforestation issue as noted below. However, our crop supply chains are the bulk movement of commodities. As such, soybeans from multiple sources are commingled. While small shipments can be separated to preserve their identity, this process is limited in scale and is expensive. Our concern is that the Sustainability Guardrails has no problem to fix with U.S. supplies but will require a very expensive compliance process that only benefits certifiers, not the environment. In fact, if identity-preserved shipments are required the lack of supply-chain efficiency could increase emissions for U.S. sourced feedstocks. CARB should convene a working group that includes agricultural representatives if it moves forward with this concept.

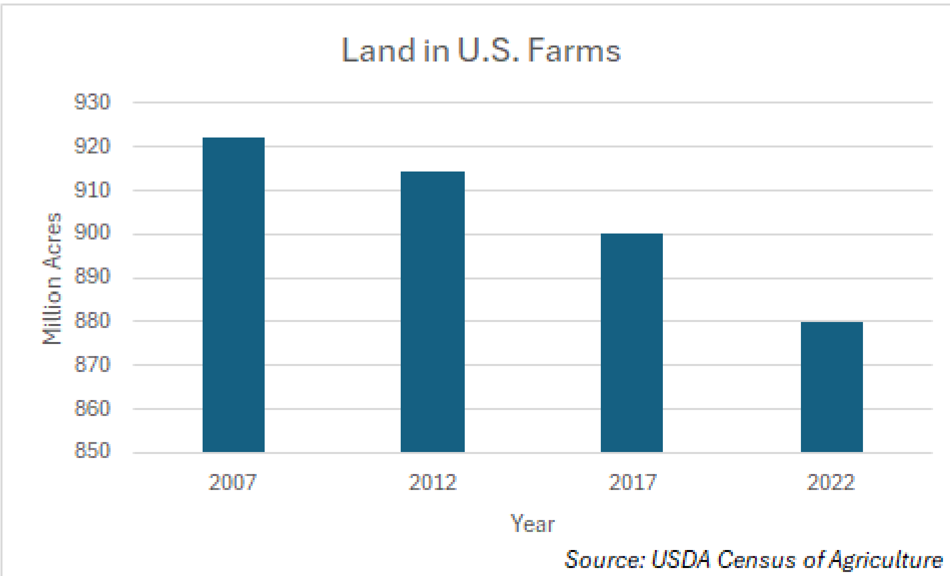
Sustainability Measures to Consider

269.5 When Congress updated the Renewable Fuel Standard in 2007, a provision was included requiring all eligible feedstock to be grown on lands cleared or cultivated by the date of enactment (December 19,

---

[1] Taheripour, F., Karmai, O., and Sajedinia, E. (2023). *Biodiesel Induced Land Use Changes: An Assessment Using GTAP-BIO 2014 Data Base*. Purdue University

2007) and non-forested. Much like the concept proposed by CARB, the intent of this provision is to prevent any deforestation or land use change that could otherwise occur due to renewable fuel incentives. Using a 2007 baseline cropland acreage of 402 million acres, EPA tracks eligible acres using annual data. To-date, U.S. cropland acreage has not exceeded the baseline, illustrating that increased crop production is based on efficiency rather than land use change. The provision helps protect against imported feedstocks that come from more environmentally sensitive areas. We support the National Oilseed Processors Association's comment letter with specific focus on how the RFS standards satisfy the desires of CARB's Feedstock Guardrails.



While EPA uses acreage in crop production, the USDA Census of Agriculture also illustrates a consistent decline in overall land in U.S. farming, as noted in the chart above. (Source: USDA Census of Agriculture)

Stakeholder Engagement

269.4 contd In addition to considering other sustainability measures which already apply to soybean farmers, ASA urges CARB to convene a working group or workshop process before finalizing any new sustainability guardrail concept. CARB will need to carefully consider limitations and financial impacts of chain of custody tracing of crop-based feedstocks, and the unintended impacts that could result from such a concept.

ASA welcomes the ability to continue engaging with CARB on this proposal and share more information on sustainability, traceability, and valuation. For such a complex proposal, it is imperative that CARB engage with key stakeholders throughout the crop-based feedstock value chain. For soy, this proposal will impact entities from the farm to the biofuel processor.

Imported Feedstocks

269.6 ASA was encouraged to see CARB propose a prohibition on palm-derived feedstocks. For clarification, ASA is interested in whether this prohibition is strictly for virgin palm oil, or all palm-derived feedstocks, including palm-based used cooking oil (UCO).

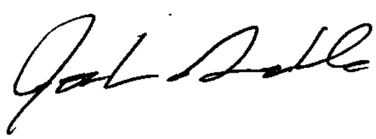
Looking more broadly at UCO, U.S. imports have become substantial and continually sets new records. While ASA sees UCO as an important component of the biomass-based diesel feedstock portfolio, concerns throughout our value chain have been rising about the integrity of UCO imports. These increased imports are coming from palm-producing parts of the world. ASA encourages CARB to look at the exporting countries' ability to generate the UCO being exported from them. Furthermore, if collection rates in foreign countries are utilizing nearly all available used cooking oil for purposes of exports, CARB should consider whether UCO from these sources is incentivizing cooking oil consumption and thereby palm oil production. Additionally, we encourage CARB to verify the integrity of UCO used in the LCFS program and will be engaging at a federal level to explore this issue in more detail.

Conclusion

ASA is encouraged by the continued successes of programs that support the development of cleaner, low-carbon fuels. We appreciate the goals of the proposed update, including CARB moving away from a proposal to cap crop-based feedstocks. Moving forward, ASA encourages CARB to utilize sound, current data in CI valuations, specifically through a long-needed update to GTAP. Further, ASA looks forward to working with CARB in finalizing an LCFS update that is not overly burdensome for agricultural producers.

ASA is eager to continue working with CARB to support the role of agriculture in diversifying the fuel supply and supporting cleaner fuel options in California and beyond. On behalf of U.S. soybean farmers, we appreciate the opportunity to comment and look forward to collaborating with CARB and other relevant stakeholders on implementation of policies that expand the use of soy-based biofuels and market opportunities for soybean farmers.

Sincerely,



Josh Gackle, President
American Soybean Association

RE: Comments On Proposed Low Carbon Fuel Standard Amendments

Carbon Ridge, Remora, Seabound, Stax Engineering, and Wärtsilä, jointly as the Mobile Carbon Capture Coalition, appreciate the opportunity to provide comments on the California Air Resources Board's (CARB) Proposed Amendments to the Low Carbon Fuel Standard Regulation (LCFS). The Mobile Carbon Capture Coalition is committed to working with CARB, other state agency partners, and all stakeholders to deliver innovative climate solutions that will provide benefits in California and beyond.

About Mobile Carbon Capture Technology

Carbon capture technologies are an important part of California's toolkit for deep decarbonization. Mobile carbon capture technologies use carbon capture directly on hard-to-decarbonize mobile sources, including Class 8 heavy-duty vehicles (semi-trucks) and marine shipping vessels.

These transportation methods are essential to our economy, but are also difficult to decarbonize. The nation's two million semi-trucks and the global shipping industry emit approximately 340 and 700 million metric tonnes of CO_2 respectively each year.[1] In addition, these high-emitting vehicles and ships will be in operation for decades to come, given the capital investments made and the need to support supply chains across the nation and world. Importantly, mobile carbon capture technology already works, with Mobile Carbon Capture Coalition members having robust partnerships with Fortune 500 companies and initial deployments.

Mobile carbon capture can also provide air quality benefits, as many mobile carbon capture technologies act as a filter on engine exhaust. Along with capturing CO_2, it demonstrates the potential to drastically improve air quality by reducing toxic air pollutants and other greenhouse gasses (GHGs) like nitrogen oxides.

Mobile carbon capture technologies can *quickly* address the most difficult sectors to decarbonize, including heavy-duty trucking, vessel shipping, and rail. Mobile carbon capture technology is a critical near-term solution that can deliver significant climate benefits and support and complement efforts toward achieving zero-emission transportation in California. When paired with renewable fuels, this innovative technology can **make transportation carbon negative** (in what is known as a bioenergy with carbon capture and storage or "BECCS" carbon removal pathway).

California is also not the only place considering the role of carbon capture, particularly mobile carbon capture, in decarbonization plans. The European Union and International Maritime Organization (IMO), the United Nations specialized agency responsible for regulating shipping, are already evaluating and implementing programs to account for reductions in emissions from mobile carbon capture. The European Union has even gone as far as integrating mobile carbon capture into its Emission Trading Scheme (ETS).

LCFS Proposed Amendment Comments

270.1 The Mobile Carbon Capture Coalition supports actions to decarbonize the transportation sector as soon as possible. California's transportation sector is the State's largest source of both GHG emissions and air pollution, accounting for more than half of statewide emissions.[2] Rapidly driving down these emissions is a critical element of California's strategy to achieve carbon neutrality. As the Governor rightly recognized in his July 22,

[1] https://www.iea.org/energy-system/transport/international-shipping
[2] See Draft 2022 Scoping Plan Update, pg. 147.

2022, letter to CARB Chair Randolph on the 2022 Climate Change Scoping Plan Update, innovative carbon capture and sequestration technologies will be necessary for California to reach its climate goals, including carbon neutrality by 2045. Additionally, SB 905 (Caballero & Skinner, 2022) further underscores the role that carbon capture technologies will need to play as part of these efforts. Solutions that can significantly reduce—and even fully eliminate—greenhouse gas emissions from California's transportation sector will be key. CARB should ensure that, as new carbon capture and removal technologies emerge, they can be quickly incorporated into the LCFS to decarbonize the transportation sector.

270.2 For these reasons, the Mobile Carbon Capture Coalition supports CARB's proposal to establish a strong carbon intensity reduction target of 30 percent by 2030 with increasing stringency in subsequent years, as the emission reductions driven by the LCFS program will be critical to ensure California remains on track to meet its climate goals. LCFS CI targets can be made more ambitious by the inclusion of a suite of transportation decarbonization technologies, including mobile carbon capture technologies that can be rapidly scaled to deliver significant climate, air quality, and public health benefits in California.

270.3 Additionally, the Mobile Carbon Capture Coalition supports the incorporation of a compliance target acceleration mechanism that can automatically adjust based on clear criteria to increase programmatic stringency. This type of mechanism will help provide critically needed emissions reductions and provide market certainty for ongoing investment in low- and zero-carbon technologies.

The Mobile Carbon Capture Coalition appreciates the opportunity to submit comments, and we look forward to continuing to work with you and all stakeholders in California on this critically important effort.

Board Comments Home

500 Capitol Mall, Suite 2360
Sacramento, CA 95814

February 20, 2024

The Honorable Steven S. Cliff
Executive Officer
California Air Resources Board
Sacramento, CA 95814

Re: Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Executive Officer Cliff:

The following comments from the California Forestry Association (Calforests) focus on the 45-day language to amend the Low Carbon Fuel Standard (LCFS) regulations released in early January. Calforests members manage over 3.5 million acres of timberland in California to the highest professional standards, with many of these acres under a combination of Habitat Conservation Plans and third party certifications.

271.1 Our concern is that the 45-day language restricts use of forest biomass resulting from sustainable forest management within California. We believe the Air Board, therefore, should revise the amendments to promote use of forest fiber from all forest management consistent with **California's Forest Practice Act**.

We are concerned with the language in the proposed LCFS amendments that makes biomass derived from legal and silviculturally justified clearcuts ineligible. Even aged management is an important tool, particularly where shade intolerant species are being restored. The language proposed would result in the elimination of an important potential source of feedstock from private landowners that would be a credible long-term feedstock supply.

The practice of clearcutting is tightly restricted by State regulations, which are set forth in the California Forest Practice Rules in Title 14 of the California Code of Regulations (CCR) at Chapters 4, 4.5 & 10. Specifically, 14 CCR Section 921.3(c) establishes circumstances under which clearcutting may be employed, as well as detailed rules regarding the extent and way it may be used. Once proposed, it is reviewed by state agencies and found in conformance with the Forest Practice Act by the Director. It is also reviewed in the context of the California Environmental Quality Act (CEQA) which further means that any adverse effect is less than significant.

Given the tightly regulated usage of clearcutting, allowing the forest residual materials that remain after a clearcut to be utilized as biomass feedstock does not encourage further clearcutting or forest degradation.

271.2 We suggest that the language in § 95488.8. Fuel Pathway Application Requirements Applying to All Classifications. section (g) Specified Source Feedstocks (1) (A) subsection 3 be amended to read as follows:

> "Small-diameter, non-merchantable forestry residues removed for the purpose of forest fire fuel reduction or forest stand improvement and from a treatment where no-clear cutting occurred, *unless from forest lands where timber operations comply with California's Forest Practice Act*; Municipal solid waste that is diverted from landfill disposal;".

California's Forest Practice Act regulations are the most stringent in the United States and set a standard for sustainability, long-term increases in forest carbon storage, and retention of forest lands.

As such, we respectfully submit that the focus should be on landscape-scale improvements to forestlands and that compliant clear-cutting practices on individual small stands of pre-existing plantations should be seen within that larger context. We recommend that the Board revise 45-day language to promote use of forest fiber from all forest management consistent with California's Forest Practice Rules.

Thank you for your consideration of these comments.

Sincerely,

George D. Gentry

Senior Vice President
California Forestry Association

350 San Francisco
350 Marin
350 Silicon Valley
350 Sonoma
Napa Climate NOW!

February 20, 2024

California Air Resources Board
Sacramento, CA

Dear Colleagues,

350 Bay Area is a non-profit organization focused on ensuring a sustainable climate and associated environmental and economic justice for all, with a reach of over twenty-two thousand people, primarily concentrated in the nine Bay Area counties. At this critical stage in the transition to renewable clean energy, California should be a national and international leader supporting real solutions based on a full life cycle analysis, rather than entrenching policies which incent counterproductive and polluting false solutions such as manure biogas and corn ethanol.

Specifically this revision of the Low Carbon Fuel Standard (LCFS) must correct the distorted economic incentives that reward some of the worst factory farming practices, both in California and across the country, providing lavish subsidies to operations that are getting paid to pollute. The program's flawed accounting practices assign factory farm biogas a lower "carbon intensity" than even solar and wind energy, creating a smokescreen for continued pollution.

Furthermore, a study found that corn ethanol, promoted through the LCFS, is 24% more carbon-intensive than traditional fuel. The enormous rise in nitrogen fertilizer to raise corn for ethanol has increased emissions of nitrous oxide, a potent greenhouse gas that is 289 times as powerful as CO2. Fertilizers used in corn production, including for ethanol, also cause vast water pollution extending from drinking water in Iowa to the Dead Zone in the Gulf of Mexico. Building ethanol infrastructure locks in ethanol and gasoline for decades, reducing incentives for investors or policymakers to shift towards more sustainable transportation.

[1]

[1] Environmental outcomes of the US Renewable Fuel Standard PNAS 2022
119 (9) e2101084119
https://doi.org/10.1073/pnas.2101084119

We urge that CARB revise the staff proposal to:

272.1 - Eliminate avoided methane crediting for fuel derived from livestock manure.

272.2 - Oppose proposed LCFS amendment loophole to allow petroleum projects with carbon capture & storage past the 2040 phase-out.

272.3 - Conduct and incorporate a full life cycle assessment of all air pollution and greenhouse gas (GHG) emissions for all pathways, and their implications for environmental justice communities.

272.4 - Create ZEV multipliers to boost electric school bus and electric public transit bus and rail system deployments.

272.5 - Eliminate credit generation from factory farm gas projects that would have happened anyway due to other programs or investments.

CARB has the power to shift California towards truly clean energy solutions and remove the incentives that enable the continued reliance on combustion fuels, especially those which artefactually increase dairy biogas and corn ethanol production. The staff proposal includes policies noted above that make the climate and pollution crisis worse. CARB must take decisive action to reform the LCFS and protect the communities most affected by its current flaws.

Sincerely,

____/sig/____

Claire Broome
Clean Energy Team Lead
350 Bay Area

SFO

San Francisco International Airport

February 20, 2024

The Honorable Liane M. Randolph
Chair, California Air Resources Board (CARB)
1001 I Street
Sacramento, CA 95814

TRANSMITTED VIA EMAIL
https://ww2.arb.ca.gov/lispub/comm/bclist.php

RE: Low Carbon Fuel Standard Missing Key Programs to Drive SAF Uplift as Key Components to Reach California's Climate and Regional Air Quality Goals

Dear Chair Randolph,

273.1 As you know San Francisco International Airport (SFO) is a global leader of sustainable aviation fuel (SAF) uplift, using ten million gallons of neat SAF delivered last year. Receipt of this fuel was exclusively enabled by CARB's 2018 Low Carbon Fuel Standard Rulemaking that incentivized SAF beyond any other state or country. Since this adoption, SFO and the Sustainable Aviation Fuel (SAF) Coalition we launched that is comprised of airlines, airports, conventional and alternative aviation fuel producers, and other nonprofit and government partners, has met with CARB staff and leadership to compel additional programs to sustain the state's SAF leadership. Further, the SAF Coalition teamed with the Speaker of the Assembly, Robert Rivas, to author the widely supported AB1322, which passed unanimously through the California Legislature, to gap analyze SAF programs that could ensure California's continued SAF competitiveness. While SFO respects the bold decarbonization vision that CARB outlined in its 2022 Scoping Plan Update, we write today to humbly request that CARB team with key members of our aviation industry, as AB1322 requested, to develop a far broader playbook than that proposed in this 2024 Low Carbon Fuel Standard (LCFS) Rulemaking to ensure the state meets Governor Newsom's 20% clean fuels adoption for the aviation sector, estimated at 1.5 billion gallons of SAF by 2030.

California and CARB must model a complete program that addresses the greenhouse gas and criteria air emissions across all sectors. Aviation efforts are falling short of our European counterparts. SFO aligns with our industry peers to urge CARB to align LCFS policy across both hydrogen and SAF to allow for book and claim accounting for low-CI electricity and RNG inputs via the use of Power Purchase Agreements (PPAs). SAF and hydrogen are both nascent industries and the state should equally allow the indirect accounting for both technologies.

SFO continues to encourage CARB to consider LCFS and other levers that can materialize new markets to recognize SAF's non-CO2 benefits, as outlined in previous communications with CARB, the California Natural Resources Agency (CNRA), the Bay Area Air Quality Management District, and GoBiz. These positive externalities include improvements to air quality, economic development through green jobs, and wildfire risk reduction, and are detailed in industry studies and should be represented in the LCFS, Scoping Plan, further CARB

Rulemaking, GoBiz programs and/or CNRA incentive structures. A recent Airport Cooperative Research Program (ACRP), administered by the Transport Research Board of the U.S. National Academies of Sciences, found that a 50% SAF blend could reduce by nearly 40% oxides of sulfur and PM reductions of up to 65%. A more recent measurement campaign found that SAF produced via the alcohol-to-jet pathway could reduce non-volatile PM by up to 97%.

The California aviation sector utilizes four billion gallons of conventional jet fuel annually. By creating new programs that enable airlines to switch to SAF, California can reduce aviation GHG emissions by 50-80% on a lifecycle basis. If aircraft in California uplifted just 5% SAF by 2025, greenhouse gas emissions avoided from those flights would total up to 2 million metric tons of CO2. Without growing AJF use, aviation sector emissions are expected to grow to over 25% of California's emissions by 2040, as other sectors (e.g., buildings, road transport) have full decarbonization pathways.

SFO has set a goal of expanding SAF use by its airlines to 5% by 2025. And while we are on our way, hitting 1% last year, achieving this goal will require 200 million gallons of SAF per year (MGY) by 2025, or 16 new SAF plants. As this goal of 200 MGY represents only about one-third of California's 2019 renewable diesel supply, it requires a rapid scaling of SAF production to be achieved.

SAF is being commercialized and is scalable, but volumes are currently small, with roughly 15 million gallons used exclusively in California last year, compared to 2.5 billion gallons of biodiesel and renewable diesel consumption. The key factor limiting SAF growth is the total monetary value that SAF producers receive when compared to that available to producers of alternative fuels to serve the on-road market. This has been quantified and detailed in a 2020 submittal by Graham Noyes ("Cap and Rack Cost" + LCFS cost) and is recognized by the industry to be approximately $0.40 per gallon. To that end, we request that CARB further review LCFS through its Public Workshops and consider revising the regulations to overcome the disparity in policies between the production of renewable diesel and SAF. Doing so will send the price signal producers need to secure investment capital to expand their facilities and increase supply to airlines uplifting SAF in California. It also offers a lifeline to renewable diesel fuel producers that exclusively serve the on-road sector, which is now obligated to increasingly electrify through State Executive Order and regulation to retrofit and retool plants for a future of aviation fueled by SAF.

With quotas and targeted SAF incentives announced and growing in Canada, the United Kingdom, Sweden, Norway, and the European Union, we hope that CARB will consider expanding the LCFS credit for SAF. Doing so will help power aviation's contribution to California's continued post-COVID and wildfire recovery in a way that keeps our state climate-competitive and fuels our industry's energy transition. While other states are starting to develop more robust SAF tax credits and incentive programs, CARB must grow SAF's LCFS credit value, or pursue other programs that can scale (not hinder) SAF as a key waypoint in California's climate emergency response planning and create a lasting legacy for our state.

We stand ready to support CARB's leadership, side by side with our airline and SAF producer peers, through the development of a mutual and robust SAF campaign that we hope you'll take on through this LCFS Rulemaking.

Very truly yours,

Ivar C. Satero
Airport Director

RE: Charm Comments on the Proposed Amendments to the Low Carbon Fuel Standard Regulation

Charm Industrial (Charm) appreciates the opportunity to submit comments to the California Air Resources Board (CARB) on the Proposed Amendments to the Low Carbon Fuel Standard (LCFS) Regulation. Charm is a California-based company working in support of State efforts to rapidly drive down greenhouse gas emissions (GHGs) on the path to carbon neutrality. Our innovative negative emissions technology can play a key role in these efforts. We look forward to continuing to work with CARB, its state agency partners, and all stakeholders to deliver innovative climate solutions that will provide benefits in California and beyond.

About Our Technology
Charm has developed a proven carbon dioxide removal technology that has already removed thousands of tons of carbon from the atmosphere. Our innovative approach converts waste biomass into carbon-rich liquid that is safely and permanently stored underground. Agricultural waste and highly combustible forest residue that would otherwise burn or be left to rot spewing GHGs into the atmosphere is instead transformed into a carbon benefit. In addition to the vital climate benefits that negative emissions technologies like bio-oil sequestration provide, our approach delivers critically needed air quality, wildfire resilience, and economic benefits in parts of California that most need them like the Sierras and the Central Valley.

Charm Supports Strong Carbon Intensity (CI) Targets and a Well Designed Auto-Acceleration Mechanism
California must build on and accelerate actions to rapidly cut GHGs. These actions must include a robust policy and regulatory framework that will take advantage of the

significant benefits that innovative carbon removal and sequestration technologies can deliver, while still prioritizing direct emissions reductions.

274.1 Charm supports the LCFS proposed amendments to increase both the pre- and post-2030 stringency of the LCFS CI benchmarks to incorporate a more stringent CI reduction target of at least 30 percent by 2030 and a 90 percent reduction in fuel CI by 2045 from a 2010 baseline, as well as an initial step-down of at least 5% in 2025. The emission reductions driven by the LCFS program will be critical to ensure California remains on track to meet its climate goals. 274.2 Additionally, a well-designed compliance target acceleration mechanism that functions to increase stringency based on program performance will support critically needed emissions reductions and provide market certainty for ongoing investment in low and zero-carbon technologies.

CARB Should Ensure that Additional Technologies are Rapidly Incorporated into the Existing Regulatory Framework for Carbon Removal within the LCFS

Charm can help support the success of an ambitious LCFS program through its proven carbon dioxide removal technology as one part of a suite of innovative technologies that California will need to meet our climate goals. The kinds of solutions that Charm has developed can also play a key role in supporting California's biomass and forest waste management goals, wildfire and forest resilience actions, and air quality goals. As a California-based company, we are invested in helping the state continue to be a climate leader by putting in place policies that pave the way for innovative technologies and solutions to support climate action. Policies that support emerging carbon-negative technologies will ensure continued investment, job creation, and economic growth for California.

274.3 Consistent with the necessary and ambitious goals for carbon removal technology detailed in the 2022 Scoping Plan, CARB should ensure that as new carbon dioxide removal and sequestration technologies emerge, they can be quickly incorporated into the existing regulatory framework for carbon removal technologies within the LCFS.

Conclusion

Charm is fully committed to helping California meet its climate goals. California is going to need a host of strategies to decarbonize virtually every economic sector in the state to achieve carbon neutrality. While we support ongoing efforts to secure direct emission reductions wherever possible, it is clear that innovative carbon removal and sequestration technologies are also going to be needed for California to reach its climate goals, including carbon neutrality by 2045.

Our company was founded to develop and bring technological solutions to the collective effort needed to turn the tide against climate change rapidly. We look forward to continuing to work with CARB on this challenge.

Sincerely,

Nora Cohen Brown
Head of Market Development and Policy

MONARCH

20 February 2024

VIA ELECTRONIC FILING

Matthew Botill
Branch Chief, Industrial Strategies Division
California Air Resources Board 1001 I Street
Sacramento, California 95814

RE: Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Mr. Botill,

Monarch Bioenergy LLC (Monarch) develops, owns, and operates several of the most significant Renewable Natural Gas (RNG) facilities in CARB's LCFS program. As a long-term participant in the LCFS program, Monarch applauds CARB for continuing to develop and enhance the LCFS program, which supports innovative Renewable Natural Gas projects in California and across the United States.

CARB continues to identify RNG's critical role in reducing methane emissions as a potent short-lived climate pollutant, as stated in CARB's 2017 Short-Lived Climate Pollutant (SLCP) Reduction Strategy. The concentration of methane in the atmosphere is increasing at an alarming rate, and there is no more effective and immediate step we can take than to aggressively and rapidly reverse emissions of fugitive methane from all sectors, including society's organic waste streams. Accordingly, Monarch respectfully submits these comments to the California Air Resources Board in response to the Proposed Amendments to the Low Carbon Fuel Standard posted on 19 December 2023.

1. Increase the 2030 Annual Carbon Intensity Benchmark from 30% to 40%

Increased program ambition is critical for continued methane reduction and growth in all low-carbon fuels. Due to the observed surplus of LCFS credits over the last two years, it is crucial to implement a significant reduction in the Annual Carbon Intensity (CI) Benchmarks. The forecast for 2030 indicates an abundance of credits compared to deficits, leading to a rapid build-up in the bank, a decline in prices, and a potential stall in low-carbon fuel investment. To address this issue and to maintain a healthy market, CARB should ideally focus on mitigating the current trend and carefully transitioning from large quarterly surpluses to modest deficits. Setting an appropriate trajectory for the CI Benchmarks and making improved target setting a pivotal aspect of the rulemaking process are excellent ways to achieve this result.

275.1 Monarch supports a more aggressive CI reduction from CARBs proposed 30% target to 40% by 2030. Throughout the rulemaking process, consulting firm ICF, with experience modeling supply and demand for clean fuel programs, has independently analyzed feasible program targets and revealed significant disparities in LCFS credit price outcomes compared to CARB's analysis[1]. The ICF analysis indicates that a 2030 target exceeding 30% CI reduction is achievable with a lower credit price trajectory than anticipated in CARB's LCFS planning scenarios.

2. Continue to support and enhance RNG projects based on methane reductions.

275.2 CARB appropriately recognizes the crucial role of reducing methane emissions in the Proposed Amendments in combating global climate change and the positive impact of RNG in facilitating methane reductions, regardless of the project's location or ultimate end-use. To address climate change, we must aggressively and rapidly reverse fugitive methane emissions from all sectors, including organic waste streams. Thus, we encourage CARB to advocate for keeping and even increasing RNG-related opportunities to boost investor confidence, accelerate methane emission reductions, and highlight the urgency of addressing methane as a potent climate pollutant on a global scale.

Leading authorities have echoed the need to reduce methane emissions. In 2023, the International Energy Agency's (IEA) report featured a dedicated section on Biogas and Biomethane[2], underscoring global acknowledgment of biogas in decarbonization. The report forecasts the deployment of renewable energy technologies in electricity, transport, and heat until 2028, addressing fundamental challenges and identifying barriers to industry growth. The IEA highlights the role of biogas and biomethane in fostering a circular economy through residue and waste valorization, contributing to rural economic development, and generating rural employment. Additionally, the US EPA has endeavored to promote anaerobic digester installation for productive energy use for the last 30 years since the inception of the AgStar program in 1994. Both reports support CARB continuing to utilize a fact-based analysis for LCFS updates.

275.3 Until there is a more effective replacement for avoiding methane emissions, CARB should continue to allow avoided methane credits as a pivotal tool to reduce methane emissions. A fixed-year phase-out of avoided methane crediting may jeopardize the viability of future agricultural RNG projects. These projects rely heavily on LCFS revenue for profitability, with avoided methane components essential for meeting capital repayment requirements. Without methane crediting, existing agricultural projects may struggle to cover operating costs, leading to potential closures and the risk of losing the opportunity to abate significant methane release. CARB should not arbitrarily embrace an avoided methane reduction phase-out without a detailed replacement policy for those emissions. This policy is essential to reduce significant LCFS project risks, avoid potentially stranding assets, and ensure continued investment and buildout of projects that can reduce organic methane release wherever possible.

3. Amend Proposed Amendments Deliverability Language

275.4 Request to amend or delete the proposed deliverability amendment language. CARB's requirements, influenced by concepts from California's Renewable Portfolio Standard (RPS), propose mandates for deliverability starting in 2041 for specific biomethane pathways. However, the 50% standard lacks environmental benefit or justification in the current physical gas system. Due to administrative complexity, this requirement could drastically reduce RNG use in California from sources outside of the state under the LCFS. Past experiences, such as RPS deliverability language, have historically created a barrier to imports, hindered facility development, increased costs, and were, ultimately, unsuccessful in creating a well-functioning California-only electric grid. We encourage CARB to revisit the state's learnings from the RPS example and remove the Proposed Amendments deliverability language.

Furthermore, a successful RNG framework should leverage existing gas system realities, avoiding assumptions of a static nature or limiting supply to specific regions. The U.S. natural gas pipeline system is interconnected and bidirectionally flowing, carefully tracking volumes throughout the system with state and federal oversight and third-party pipeline metering. Repurposing the established natural gas infrastructure for efficient delivery of a low-carbon fuel blend, including RNG, aligns with efforts to reduce gas demand through enhanced energy

[2] https://www.iea.org/reports/renewables-2023/special-section-biogas-and-biomethane

efficiency and electrification. Given RNG's physical interchangeability with fossil natural gas, distributing it within the longstanding pipeline system that has efficiently served California for decades is feasible. Therefore, a 50% flow requirement is arbitrary and unjustified, as the gas system's bidirectional nature allows for effective RNG movement across North America.

We encourage building an RNG framework based on the realities of existing gas systems without assuming static conditions and urge CARB to avoid implementing RNG deliverability requirements that favor fossil gas in the interest of fairness and practicality within the gas system.

4. Triggering the Auto Acceleration Mechanism

275.5 Monarch supports adopting an Automatic Accelerator Mechanism (AAM) and amending the proposed language to trigger the AAM earlier. The AAM is a complementary refinement to the step-down in program stringency within the LCFS. This mechanism will dynamically respond to sustained and significant CI reductions by tightening programmatic stringency, increasing investor certainty in credit markets.

Acknowledging the challenges in predicting technological innovation and feedstock availability, the AAM aims to adjust the program's stringency when the market significantly surpasses the set requirements. This feature automatically responds to significant and sustained credit generation beyond program targets while enhancing overall LCFS certainty. By doing so, it encourages ongoing investments and innovation in clean fuels. The credit bank expands when the program experiences substantial overperformance, slowing innovation and investment in low- and zero-carbon fuels. The AAM addresses this by giving the market greater certainty that the program's stringency will automatically adjust based on publicly available data, ensuring a transparent and predictable response to surplus credit accumulation over an extended period.

While CARB's current timeline suggests the AAM's implementation in 2028, Monarch recommends allowing 2025's performance to trigger the AAM. By doing so, CI reduction targets for 2027 will commence one year earlier than in the Proposed Amendments. This clarifies and improves Monarch's ability to make significant additional capital investments in decarbonization projects.

Monarch Bioenergy appreciates this opportunity to contribute to the ongoing dialogue on these central decarbonization topics. We greatly appreciate CARB's continued efforts to find the best solution for the industry and your constituents. Your commitment to addressing these issues is vital for our industry and highly appreciated. We trust that the outcome will reflect a robust and practical framework for the benefit of all stakeholders. Thank you.

Sincerely,

Sean M. Lock

Union of Concerned Scientists

To: California Air Resources Board

From: Jeremy Martin, Daniel Barad, Samuel Wilson, David Reichmuth and Don Anair

Date: February 20, 2024

Subject: LCFS Amendments

The Union of Concerned Scientists (UCS) is a long-standing supporter of the Low Carbon Fuel Standard (LCFS) and has been actively involved in its implementation for more than 15 years. We urge the California Air Resources Board (CARB) to modernize the LCFS to ensure it equitably meets the needs of Californians and supports the attainment of air quality standards. Beyond California's borders, the LCFS is an important policy model for other states and the federal government, which could help address the many deficiencies of the Renewable Fuel Standard. But to meet these needs the LCFS must be modernized, to rebalance credit markets, provide reliable support for non-combustion pathways, strengthen safeguards against deforestation and the diversion of food to fuel use and phase out counterproductive methane digester subsidies that are contributing to dairy and meat industry consolidation.

Rebalance supply and demand for credits by reducing credits that are misaligned with California's goals rather than focusing entirely on increasing stringency.

The low credit prices and growing bank of credits do not simply reflect success and signal a need ramp
stringency faster but are instead sign of disfunction, as a huge share of credits are awarded to vegetable
276.1 oil-based renewable diesel and manure biomethane pathways that do little or nothing to benefit California
and create major problems elsewhere. A durable solution must address the root cause of the problem by
limiting the supply of these counterproductive credits. Limiting supply will stabilize credit prices without such dramatic increases in overall stringency, which will reduce regressive passthrough costs to California drivers of gasoline powered vehicles. While passthrough costs have been very modest to date, CARB should carefully consider the impact of the LCFS on costs to drivers from increasing stringency. Support for transportation electrification has clear returns to California drivers (and people breathing the air) but the same is not true for bidding up the global price of vegetable oil or subsidizing manure digesters in other states.

Update transportation electrification provisions to support a fast and equitable transition.

The LCFS provides vital support for transportation electrification, and as such it underpins other critical regulations that help cars and heavy-duty trucks transition to zero emission vehicles. The Total Cost of Ownership analysis used for the Advanced Clean Fleets Rule was based on an LCFS credit prices of $200
through 2030, while recent prices have been below $80 which creates problems for these policies. CARB
should ensure the LCFS continues to support the transition to electrification by retaining a 2.5% credit
cap for light duty vehicle fast charging infrastructure credits, increase the flexibility and overall credit cap
for the proposed medium and heavy-duty infrastructure credits, facilitate electrification of other modes
276.2 and applications by establishing default energy economy ratios, and support a combination of
electrification and vehicle mile traveled reduction by updating LCFS eligibility for fixed guideway
systems and establishing credit multipliers for mass transit vehicles. Specific recommendations for
improvements to transportation electrification provisions are below.

Cap compliance from vegetable oil-based biofuels to ensure the LCFS doesn't exacerbate global hunger and deforestation.
We published extensive analyses earlier this year on the implications of the boom in renewable diesel consumption in California for global food markets and deforestation (Attachment 1) and why a cap on the use of vegetable oil-based fuels for LCFS compliance is essential to avoid this harm and stabilize the LCFS (Attachment 2). The reasons given in the Initial Statement of Reasons (ISOR) to reject a cap on virgin oil-based fuels in Alternative 1 are based on inaccurate claims of climate and air quality benefits
276.3 and associated health outcomes, which double count climate benefits already required by federal law and ignore CARB's own research on air quality benefits from new technology diesel engines running on renewable diesel. A corrected analysis would show that there are few if any real climate or air quality benefits associated with unlimited use of vegetable oil-based fuels and there are enormous harms. The proposed sustainability guardrails are inadequate because they do not address vegetable oil diverted from
276.4 food to fuel use. Alternative 1 discussed in the ISOR is a useful step forward, but a better solution would
276.5 be to limit the use of all lipid-based fuels at a reasonable share, certainly less than half, of the feedstock available for fuel production in the United States, or about 1.5 billion gallons. While chain of custody
276.6 tracking is an inadequate safeguard against deforestation, it should be implemented for used cooking oil to reduce the risk of fraud.

276.7 **Phase out credits for "avoided methane emissions" and limit LCFS carbon intensity scores to no less than zero to wind down what has become in effect a poorly run offset program.**
We recently published an analysis of the problems caused by crediting manure digesters with avoided methane emissions, substituting an energy subsidy for a much-needed pollution regulation, and creating what is in effect a poorly run offset program (Attachment 3). Negative carbon intensity scores have no place in the LCFS. The LCFS should support the transition away from fossil fuels and hold all fuel producers accountable for pollution in their own supply chains. The California Legislature gave CARB the authority to start regulating dairy pollution in 2024, and CARB should start developing these regulations. However, instead of winding down the subsidies, the ISOR is doubling down, suggesting credit for avoided methane pollution could remain in place for decades after the legislature granted CARB
276.8 the authority to regulate and extending the problems into the power and hydrogen sectors. Using negative carbon intensity (CI) biomethane to generate negative CI electricity or hydrogen is greenwashing, which will subsidize digesters in other states in place of supporting investment to reduce emissions in California.

Carbon sequestration associated with enhanced oil recovery or any fossil fuel extraction should not be credited under the LCFS.
276.9 SB 1314 and SB 905 make it clear the legislature does not support carbon dioxide captured for use in enhanced oil recovery and therefore CARB should exclude this use of sequestered carbon from credit generation within the LCFS whether it occurs within California's borders or outside. Expanded federal support already provides generous support for the use of captured carbon dioxide, and adding LCFS compliance value to federal tax credit effectively subsidizes oil-extraction at the expense of California drivers.

Transportation electrification

To address climate change and reach California's goals of net zero emissions by 2045, the rapid electrification of mobile emissions sources is needed. The LCFS provides a vital source of investment in transportation electrification which complements other state, federal, local, utility, and private investment. Hence the proposed changes to the transportation electrification elements of the LCFS program are particularly important for keeping California's transition on track. UCS urges the following modifications to the proposed electrification components to increase the effectiveness in LCFS support for transportation electrification.

Light-Duty

The fast-charging infrastructure credits for light-duty vehicles have supported the further development and expansion of charging infrastructure in CA and can be a continued catalyst for investment through 2035 as the transition towards 100 percent zero emission vehicle sales continues. UCS urges CARB to
276.10 maintain a program cap of 2.5% credits through 2035, rather than reducing the cap to 0.5% as proposed and to maintain the current power and charging port limits of the current program.

CARB should update the Energy Economy Ratio (EER) for light duty plug-in electric vehicles to reflect the current efficiency of vehicles sold. Based on sales over the prior 5 years, the sales-weighted and utility
276.11 factor-weighted average efficiency of plug-in light duty EVs was 0.305 kWh/mi.[1] When compared to the most recent average fuel economy for the light duty fleet (26.0 mpg), an EER of 4.2 is justified.[2] At a minimum, CARB should increase the EER to 4.0 from the current value of 3.4 approved for light duty electric vehicles.

Heavy-duty

Medium- and heavy-duty vehicles (MHDVs) are responsible for the most significant contributions of lung-damaging and ozone-forming pollutants from vehicles on California's roads and highways. As such, CARB has adopted several transformative regulations, including the Advanced Clean Trucks and Advanced Clean Fleets rules, to accelerate the economy-wide transition to zero-emission trucks and buses. While these rules are necessary to increase vehicle availability and adoption, the LCFS also plays a vital role in this transition, particularly given the large amount of fuel consumed by commercial vehicles and the potential for the program to generate support for early adopters of clean trucks and buses and companies providing charging infrastructure.

We appreciate the recognition of the unique electrification needs of MHDVs compared to LDVs in the draft. However, the current draft could be significantly improved upon by better accounting for the diverse duty cycles and charging needs of currently deployed and forthcoming battery-electric MHDVs, particularly in the language regarding charging infrastructure credits. Where the current draft does not
276.12 maximize potential near-term investments and deployment of zero-emission MHDVs, several tweaks could accelerate and embolden the much-needed transition to electric delivery, short-haul, vocational, and drayage trucks. At the highest level, the LCFS should better balance vastly different electrification barriers and opportunities within MHDV classes and duty cycles.

Increase flexibility of funding for critical electrification catalysts

Staff's current proposal includes a cap on credits for Fast-Charging Infrastructure (FCI) of 2.5 percent of deficits. While we understand the need for LCFS revenue to support a wide range of projects, funding priorities within the program should reflect both the dire need to reduce emissions from the MHDV sector

[1] New electric vehicle sales data for 2019-2023 as reported by the California Energy Commission "ZEV and Infrastructure Stats Data", online at https://www.energy.ca.gov/files/zev-and-infrastructure-stats-data. Model vehicle fuel economy values and plug-in hybrid range data was sourced from US EPA and Department of Energy's fueleconomy.gov website.
[2] "The 2023 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975", EPA-420-R-23-033, December 2023.

and the financial barriers facing early adopters and developers of charging infrastructure. FCI is most likely to serve Class 7 and 8 tractor trucks, which consume the largest amount of fuel and contribute the highest amount of pollution among the state's MHDV fleet, despite being a small fraction of total trucks and buses. Additionally, where most commercial electric vehicles are likely to charge at depots, long-haul tractor trucks are far more likely to rely on publicly available FCI as a primary fueling source.

276.13 Given this, it becomes apparent that the development of high-power FCI is a primary barrier to an accelerated shift to zero-emission long-haul freight. Increasing the cap on FCI credits, or developing a dynamic cap based on real-world data including vehicle registrations and ZEV deployment goals, is necessary to address the often-cited barrier of FCI deployment and the very real problem of climate-warming and toxic air pollution from long-haul trucks.

276.14 A successful LCFS can and should facilitate accelerating the electrification of both "low-hanging fruit" and "harder-to-electrify" MHDVs. While FCI development is a primary barrier for long-haul electrification, the vast majority of commercial vehicles in operation – straight trucks, delivery vans, and the like – are unlikely to use public charging regularly or require FCI access due to lower daily mileage and tendency to return to depots each night. According to the US Census Bureau's 2021 Vehicle Inventory and Use Survey data, *78 percent of non-tractor MHDVs travel less than 50 miles on a typical day*.[3] Because of this duty cycle, model availability, and total-cost of ownership upsides, these vehicle types are ripe for early electrification. However, the current draft's prohibition of credit generation at lower power charging depots removes economic incentives for these fleets to electrify sooner. Additionally, high power charging requirements for credit generation may lead to fleets pursuing charging capabilities greater than their needs, which may lead to interconnection delays. It is important that the LCFS include flexibilities that promote the "right-sizing" of charging infrastructure for different types of vehicles and duty cycles.

Geographic and station size restrictions may hinder near-term MHDV electrification

276.15 Current draft language in Section 95486.3 limits the eligibility of MHDV FCI to areas including Federal Highway Administration Alternative Fuel Corridors and areas currently used for MHDVs parking. We assume that staff's inclusion of geographic and charging station power restrictions were meant in some way to focus LCFS support to charging infrastructure development in the most appropriate areas. However, the proposed restrictions are excessive and premature given the current state of the zero-emission MHDV market and infrastructure deployment.

While we appreciate that the current proposed language may be intended to prioritize some of the hardest to electrify MHDVs, the program should include flexibilities to respond to both current and future market trends and align with the ACT and ACF's influences on the market. The proposed geographic restrictions may reduce opportunities for developing zero-emission fueling stations geared towards regional haul and last-mile delivery vehicles in the near term. As mentioned above, these vehicles are far more likely to return to a home base depot each night and are currently well-suited for electrification given their duty cycles and model availability. These vehicles are also on an accelerated electrification timeline in both the ACT and ACF. The LCFS would be in better alignment with these market trends and regulations by allowing for increased geographic flexibility.

Increasing geographic flexibility may help to address common barriers to charging station development including grid capacity, land availability, and zoning. By restricting eligibility to sites currently used as

---

[3] United States Census Bureau. "Vehicle Inventory and Use Survey Public Use File." Accessed January 2024. https://www.census.gov/data/datasets/2021/econ/vius/2021-vius-puf.html

vehicle parking or depots, the program fails to consider that these sites may not have existing grid capacity to support fleet electrification. As such, opportunities to accelerate near-term freight electrification may be stifled. A more strategic approach may be to consider phased-in restrictions that consider factors such as market trends, vehicle availability, and grid readiness and aligns with existing regulatory requirements for fleets and vehicles manufacturers.

276.16 While we support increasing geographic flexibilities for zero-emission fueling stations, the program should include restrictions to avoid increasing traffic and noise burdens in communities adjacent to freight and industrial operations. We encourage CARB to work directly with these communities and consult pollution and traffic data when designing credits and incentives for ZEV fueling stations.

276.17 The program should also allow for additional station size and power flexibilities over the near term to influence accelerated zero-emission MHDV deployment. The proposed restriction of 10 FSEs or 10 MW for MHD-FCI sites within one-quarter mile may reduce appetite for early investments in station development. We understand the need for balanced credit generation to maintain sustainable credit prices, however, such restrictions should not be placed on electrified commercial transportation given its emerging natural and clear environmental upsides over combustion fuels.

276.18 Finally, we recommend that rule language regarding restrictions be placed with corresponding eligibility language (such as that in Section 95486.2 (b)(1)), rather than with application requirements, to improve readability.

Facilitate support for electrification of other applications

276.19 There are many electrification opportunities beyond cars and trucks that can contribute to lowering carbon and other tailpipe emissions from the use of combustion fuels. However, they lack a readily accessible pathway to participate in the LCFS. CARB should establish default EERs for equipment, vehicles, and vessels in emerging electrification applications such as agriculture and forest management, mining, marine, aviation, and other off-road to facilitate market participation and encourage greater electrification. Establishing default, conservative EERs would provide support for these emerging opportunities and minimizing complexity and barriers to participation.

Prioritize support for zero emissions transit to support communities and reduce car dependence

276.20 To ensure the LCFS is aligned with the vehicle mile reduction targets of the scoping plan, CARB should remove the penalty on credit generation for fixed guideway systems installed prior to 2011. This penalty is inconsistent with the treatment of other fuels and should be corrected to ensure the LCFS appropriately supports one of the most vital strategies to support CARB's Policy Framework to Advance Sustainable and Equitable Communities. If older fixed guideway transit system were treated the same as newer systems, they would generate 3.1 to 4.6 times as many LCFS credits, depending on the type of vehicles that use the system. This would help cash-strapped systems maintain and improve service, reduce car dependence and ease the associated burdens that are inequitably borne by California's low-income communities and communities of color.

276.21 CARB should also implement a credit multiplier for zero-emissions mass transportation vehicles to account for the outsized impact of vehicles that reduce vehicle miles travelled on the carbon-intensity of California's transportation fuels. For example, a 2x multiplier would be appropriate in support of the Scoping Plan objective to double transit capacity and service frequency by 2030.

Attachment 1. Everything You Wanted to Know About Biodiesel and Renewable Diesel. Charts and Graphs Included

January 10, 2024. Available online at https://blog.ucsusa.org/jeremy-martin/all-about-biodiesel-and-renewable-diesel/

Back in 2016 I wrote a long post about biodiesel, explaining what it is made from (mostly vegetable oil) and arguing that EPA should show restraint in setting targets for biodiesel because of the limited availability oils and fats and the harmful consequences of drawing too heavily from these limited sources. The world has changed in many ways since 2016, but the large-scale diversion of vegetable oil from food to fuel remains a bad idea. Now it is California policymakers' turn to establish sensible guardrails on fuel policies to avoid creating problems in California, and around the world.

Since 2016, EPA has generally shown restraint in setting targets for biodiesel and related fuels, insofar as the law allows, and biodiesel consumption has actually fallen. But in its place renewable diesel is booming, produced in large oil refineries retrofitted for the purpose and consumed primarily in California. Biodiesel and renewable diesel are closely related fuels made from the same oils and fats, which remain scarce, expensive, and linked to deforestation and food price spikes.

For this reason, it is important that policy makers, not only at EPA but also in California, are realistic about the sustainably available supply of oils, and implement fuel policies to avoid excessive diversion of vegetable oil into transportation fuel production. The idea that a large number of oil refineries can keep humming along by replacing petroleum diesel with vegetable oil or used cooking oil is a dangerous illusion. Biofuels can play a productive role when used at a sustainable level. But we need to be realistic about where they come from, and limit feedstocks to sustainable resources used at a reasonable scale to avoid turning a helpful tool into a harmful dead end.

This article draws heavily from a series of articles on the Renewable Diesel Boom by Maria Gerveni, Scott Irwin and Todd Hubbs at farmdoc daily that I heartily recommend for more quantitative economic analysis. The conclusions and policy recommendations are purely my own.

Biodiesel and renewable diesel are mostly made from vegetable oil

Biodiesel and renewable diesel are made from the same starting materials, are both blended into diesel fuel, and are supported by the same regulations. Collectively biodiesel and renewable are referred to as bio-based diesel, which is especially relevant when considering the availability of oils and fats.

More than 80 percent of bio-based diesel is made from vegetable oil (the rest is mostly animal fats). The soybean and canola oil that make up the majority of biodiesel is basically the same as the cooking oil you buy at the grocery store, while the corn oil is mostly an inedible byproduct of ethanol production that is generally used for animal feed and other purposes. Yellow grease is a catch all term that includes used cooking oil as well as lower quality tallow from rendering facilities.

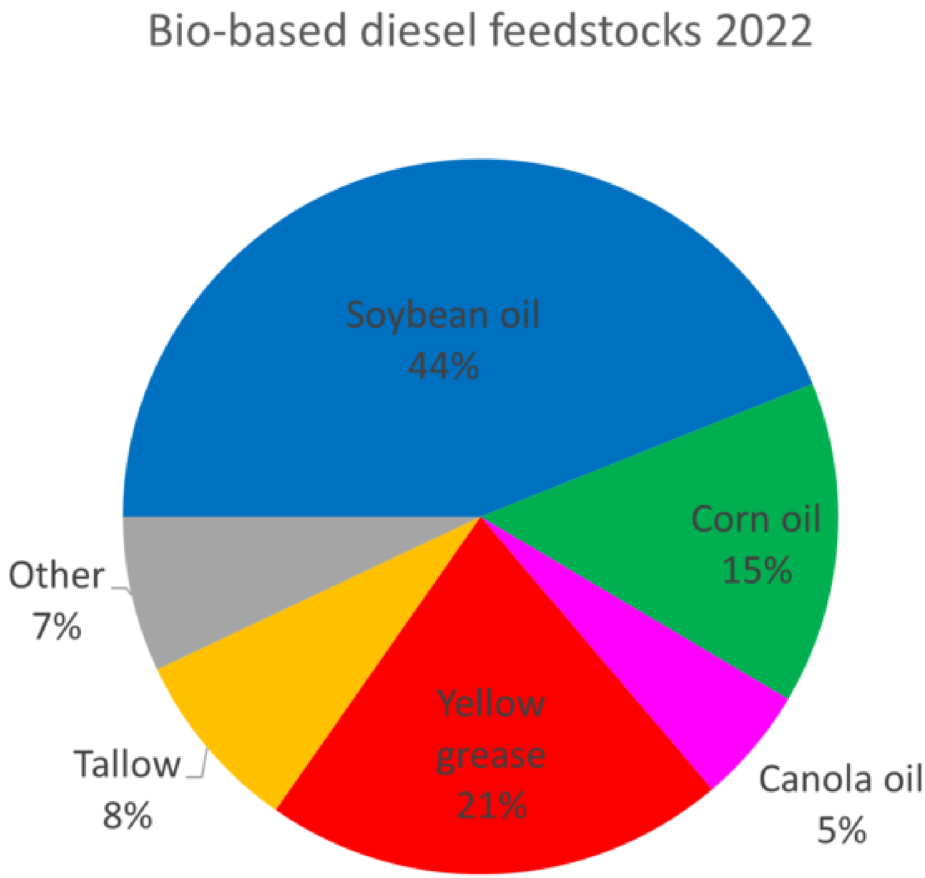

Figure 1. Most bio-based diesel fuels are made from vegetable oil. The chart above shows the oils and fats used to make biodiesel and renewable diesel in 2022. (Source EIA Monthly Biofuels Capacity and Feedstocks Update)

Using more oils and fats for fuel instead of food and animal feed has consequences for competing users of these products and for the global agricultural system. Of particular importance from a climate perspective is the relationship between rising use of oils and fats for fuel in the United States and soybean expansion in South America and palm oil expansion in Southeast Asia, both of which are major drivers of deforestation and global warming pollution. Figure 1 above shows that palm oil itself is not a significant direct source of US biofuel production. However, there are important indirect links between how much soybean oil bio-based diesel we use in the US and how quickly palm oil plantations expand in Indonesia or Malaysia. I'll get to these connections shortly, but first, let's consider the relationship between biodiesel and renewable diesel.

Renewable diesel is the fastest growing part of the US biofuel market

Biofuels overall account for a small but growing share of US transportation energy. Figure 2 shows that petroleum supplies 94 percent of US transportation energy while biofuels are 6 percent. Of the biofuels, ethanol, biodiesel and renewable diesel make up 70, 13 and 14 percent respectively. Ethanol consumption grew rapidly between 2000 and 2010 but after 2010 biodiesel took over as the major source of biofuel growth before being eclipsed by renewable diesel after 2016.

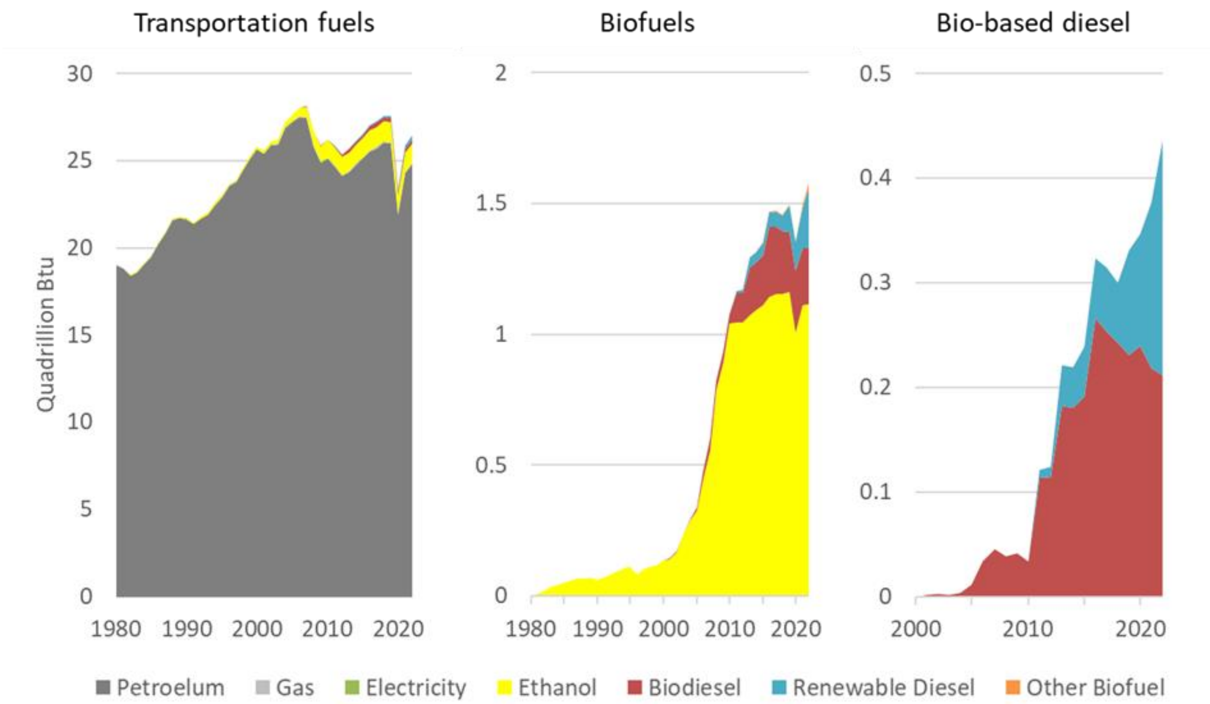

Figure 2. While ethanol remains the largest US source of biofuel, biodiesel and more recently renewable diesel have accounted for most of the growth since 2010. Source US Energy Information Administration.

Biodiesel versus renewable diesel

Biodiesel and renewable diesel have several similarities and a few key differences. Both fuels are made from vegetable oils and fats and are blended into diesel fuel. Both fuels satisfy the requirements of the Federal Renewable Fuel Standard (RFS), which requires oil companies to blend biofuels into the gasoline and diesel they sell. So, in that sense biodiesel and renewable diesel compete for both feedstock and customers.

Biodiesel = an additive blended into diesel
Renewable diesel = a replacement for diesel fuel
Bio-based diesel = biodiesel + renewable diesel

Although biodiesel and renewable diesel are derived from the same feedstocks, the processes used to make them are different. Renewable diesel production uses a hydrogen treatment to remove oxygen from the fats and oils, while biodiesel is produced by a less complex process and retains some oxygen.

Renewable diesel, like fossil diesel, is a pure hydrocarbon and is so similar to fossil diesel that they can be used interchangeably. That is why renewable diesel is often described as a “drop in” fuel. By contrast, biodiesel is limited to specific maximum blends (usually 5 or 20 percent) and higher blends must be specially labeled and their use is limited to compatible vehicles.

The hydrogen treatment used to remove oxygen from the fats and oils increases the costs of renewable diesel production, but adds flexibility, so the latter may be produced from animal fats that are less readily made into biodiesel.

These differences also connect to historical and geographical differences. The growth of the biodiesel industry was promoted by soybean producers as a way to expand the market for soybean oil. As such it is not surprising that the Midwest has 70% of U.S biodiesel capacity, which is primarily in Iowa, Missouri, Illinois, and Indiana.

The renewable diesel industry is less centralized, but the largest share of production capacity, 60 percent, is in the Gulf Coast states, primarily Louisiana and Texas. US renewable diesel production was initially linked to animal fat. Tyson Foods helped launch a Renewable Diesel facility in Geismar, Louisiana that started up in 2010 as the first large US producer of renewable diesel made from animal fat.

More recently, much of the growth in renewable diesel has been from converted oil refineries, which already have the facilities for hydrogen treatment as well the logistics to receive trains or tanker ships of incoming oil (fossil or vegetable) and ship out finished diesel fuel. The oil industry increasingly controls bio-based diesel fuel production. Among other links, in 2022 Chevron purchased the largest biodiesel producer in the US, the Renewable Energy Group, and Marathon Petroleum and Phillips 66 are converting oil refineries to produce renewable diesel.

Perhaps the most notable difference between biodiesel and renewable diesel is that since 2016 renewable diesel consumption has been booming while biodiesel consumption has been declining. Biodiesel consumption in the US peaked in 2016, and by 2022 had declined 24 percent, while renewable diesel use has risen rapidly, growing almost 4-fold between 2016 and 2022. In 2022 renewable diesel surpassed biodiesel for the first time and combined the two sources of bio-based diesel now account for 7.3 percent of US diesel fuel consumption by volume.

Renewable diesel is (mostly) a California story

Most of the renewable diesel consumed in the United States is consumed in California (Figure 3). The concentration of renewable diesel in California is partly the result of California's Low Carbon Fuel Standard policy, discussed later in this post. In 2022 California consumed half of US bio-based diesel. Rising California consumption has come partly at the expense of biodiesel consumption elsewhere in the US, which fell 28% percent in 2022 compared to its peak in 2016.

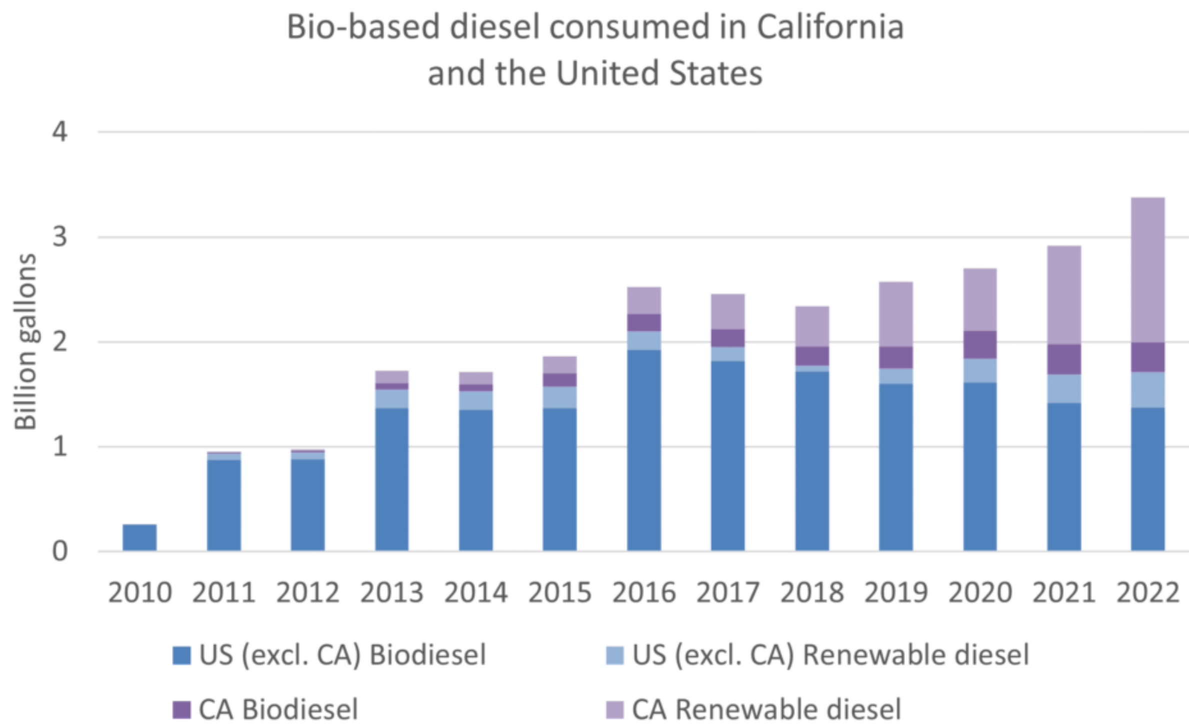

Figure 3. Since 2016 California has dramatically increased consumption of renewable diesel, partly at the expense of biodiesel used elsewhere in the US. California Air Resources Board, US Energy Information Administration.

The blend rate of bio-based diesel in California is rising rapidly. In the first half of 2023, the combined share of renewable diesel and biodiesel rose to 59 percent of total diesel fuel use in California. Outside of California the share of bio-based diesel has fallen from 5 percent in 2016 to only 3.8 percent in 2022. A recent analysis from researchers at the University of California Davis found a 50 percent chance that petroleum diesel would disappear from California by 2028.

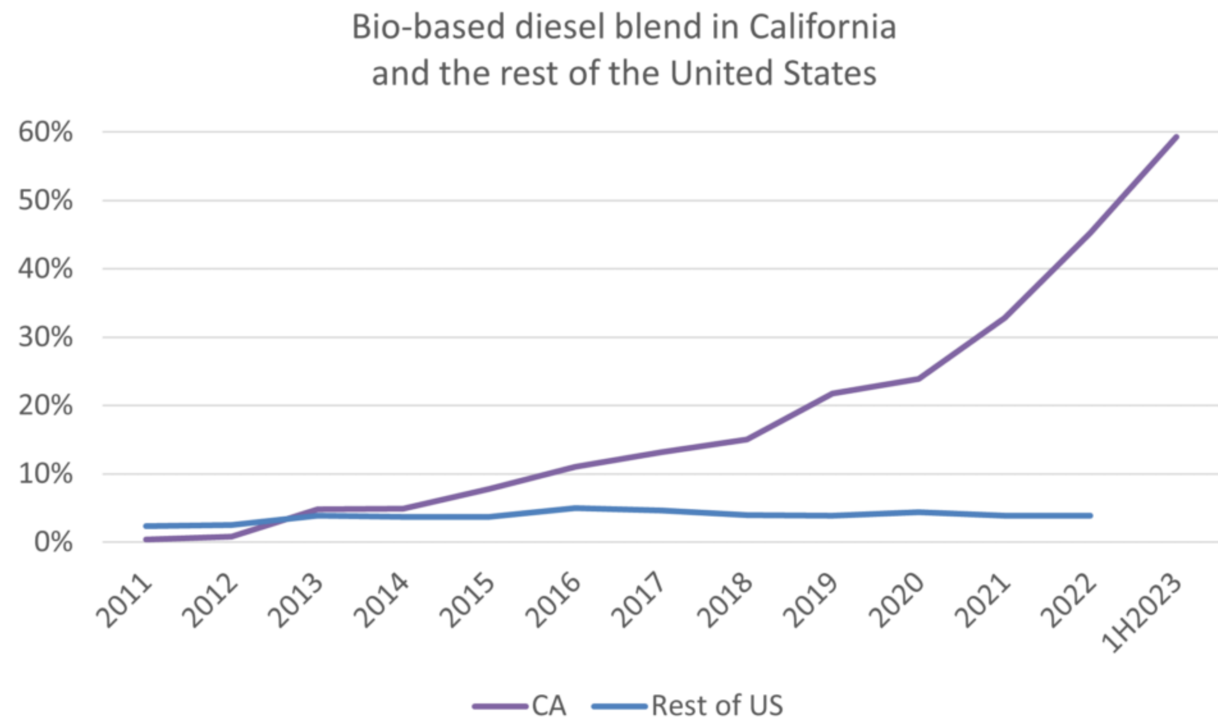

Figure 4. The share of renewable diesel and biodiesel blending into diesel fuel sold in California has grown rapidly and in the first half of 2023 it reached 59 percent. Outside of California the blend rate fell, from a peak of 5 percent in 2016 to 3.8 percent in 2022. Source California Air Resources Board, US Energy Information Administration.

Renewable diesel production capacity is poised to grow rapidly

Renewable diesel production capacity in the United States is in the middle of a massive expansion. Production capacity grew by 400 percent between 2019 and 2022 and based on announced and planned projects, it could double again by the end of 2024. The figure below from a recent analysis of *farmdoc daily*, March 29, 2023 illustrates the massive, planned capacity buildout for renewable diesel. Whether all these facilities get built and operate at their full capacity depends a lot on policy decisions in California, DC and elsewhere.

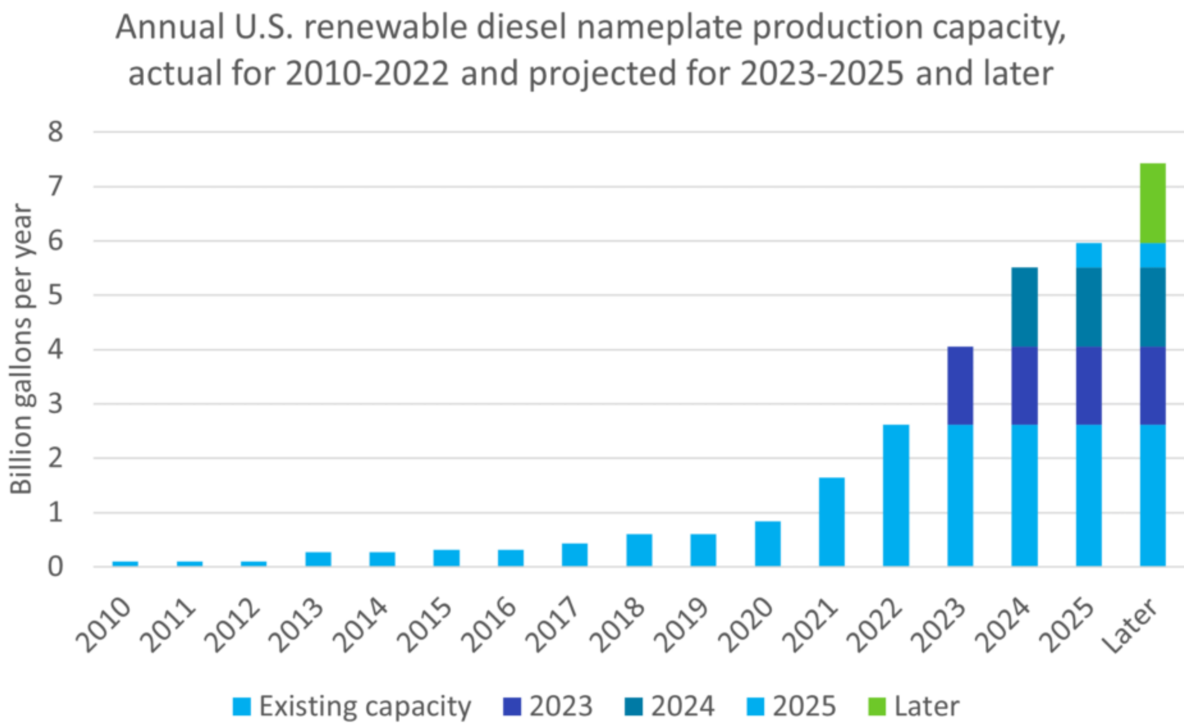

Figure 5: Renewable diesel production capacity has expanded dramatically and is poised to grow much further. farmdoc daily, [March 29, 2023](#).

California is at the eye of the storm, both as the main driver of demand and soon as a major producer as well. Two thirds of the capacity planned for 2023 and 2024 is in California, especially two projects in the San Francisco Bay area, the Marathon Martinez and Phillips 66 Rodeo refineries. These two facilities plan to bring on-line capacity of more than 1.4 billion gallons by the end of 2024.

Converted oil refineries

An important caveat to keep in mind when looking at renewable diesel capacity growth announcements, both recent and planned, is that the renewable diesel production facilities are generally not new facilities being built from the ground up for renewable diesel production. Many are oil refineries being converted from fossil fuel production to renewable fuel production. Petroleum refineries are massive compared to biofuel facilities. The difference in scale reflects both the larger scale of the demand for petroleum fuel and the economies of scale associated with the required facilities and infrastructure, including pipelines and ports to offload crude from tankers. Biofuel production facilities have generally been built on a smaller scale, reflecting the economic advantage of producing the fuel closer to where the vegetable oil or animal fat is produced.

Because oil companies are converting facilities they already have, the decision on capacity is based in part on the scale of the facilities they are converting. If these were new construction projects, the massive capacity expansions might be interpreted as reflecting a strong belief by investors that demand is likely to expand a commensurate amount, otherwise it would be foolish to invest their money. But for an oil company with an excess refining capacity, the decision to convert to renewable diesel may have a much lower threshold, and the capacity may be a function of the capacity of the existing infrastructure as much as a bet of new money on the scale of a new opportunity.

Another motivation for renewable diesel conversions is to help oil companies more cost effectively meet their obligations under the federal RFS and state fuel policies. The RFS requires companies selling gasoline and diesel to purchase biofuels to blend into the fuels they sell or else purchase credits from others who sell biofuels. The decision to convert an unneeded oil refinery to renewable diesel production facility reflects a decision that it is more cost effective to buy the feedstock and directly produce the fuel required for compliance compared to buying the fuel or associated credits from someone else. Selling renewable diesel in California also helps refiners satisfy the requirements of the California LCFS.

Finally, the conversion of a petroleum refinery to renewable diesel is attractive in part because it forestalls the need to begin a costly and complicated process of decommissioning an old refinery. UCS commissioned a recent report about lessons learned from the closure of a Philadelphia Oil refinery, which highlights how reluctant refiners are to close their refineries. A conversion to renewable diesel postpones the day of reckoning and gives the refinery owner more time to develop the most advantageous exit strategy.

The bottom line is that oil companies have a clear motivation to overstate the potential to convert oil refineries to biofuel production. The realistic potential for biofuel conversions is quite small because of the limited availability of suitable feedstocks. Exaggerated hype about potential for refinery conversions to biofuel production amounts to greenwashing that distracts from more scalable solutions.

Fuel markets are much bigger than feedstock markets

Securing adequate feedstock is a very different challenge than finding excess petroleum refining capacity. It is clearly not feasible for many states or the whole country match the rapid scaleup of bio-based diesel underway in California because the feedstocks are just not available. To produce 100 percent of 2022 US diesel fuel consumption in the transportation sector would require more than 160 million metric tons (MMT) of feedstock, which is 10 times US production of vegetable oils in 2022 or 80 percent of global vegetable oil production in 2022 (Source US Energy Information Administration, USDA Foreign Agricultural Service)[4]. To get a handle on the realistic potential for bio-based diesel, and the consequences of rapidly ramping up production, we need to explore the current and potential future supply of feedstock.

Where does the feedstock come from?

Figure 6, produced using data from *farmdoc daily* December 11, 2023, December 20, 2023, illustrates the feedstock used to produce the bio-based diesel fuels produced in the United States. Total feedstock consumption more than doubled in the last decade, exceeding 11 MMT in 2022. Imported bio-based diesel fuel consumed another 1.0 MMT of feedstock for fuel production abroad, so total US bio-based diesel consumption in 2022 required 12 MMT of feedstock, half of it to supply fuel to California.

[4] In the discussion of feedstock requirements I make a few simplifying assumptions about conversion rates and report everything in millions of metric tons (MMT). My estimates are based fuel consumption data from EIA reported in gallons and assuming 7.55 pounds of feedstock per gallon for biodiesel and 8.125 pounds per gallon for renewable diesel, consistent with *farmdoc daily*, May 1, 2023. Actual values will vary by feedstock, conversion process and facility, but this should be a reasonable and consistent approximation.

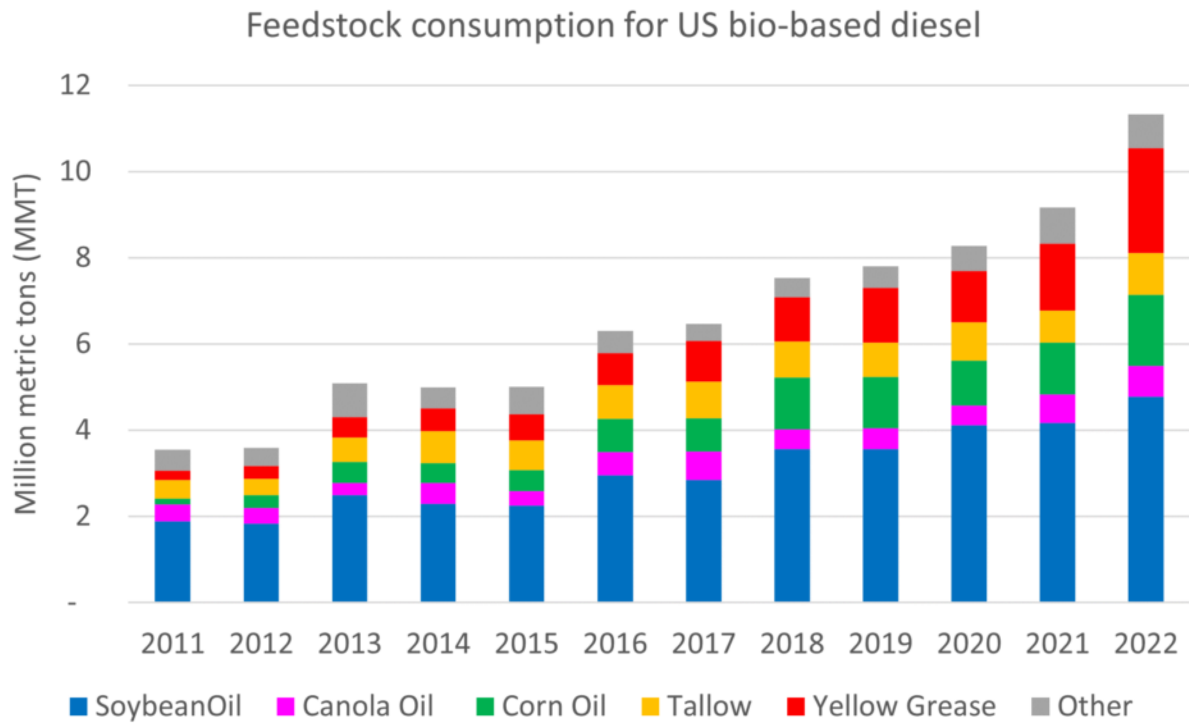

Figure 6. Feedstock consumption for bio-based diesel fuel produced in the US has more than doubled since 2012 and exceeded 11 MMT in 2022. Source *farmdoc daily* December 11, 2023, December 20, 2023.

Soybean oil is by far the most important source of bio-based diesel feedstock, accounting for almost half of the total. Combined with corn and canola oil, vegetable oils make up more than two thirds of feedstock. Yellow grease and tallow make up most of the remaining oil. Yellow grease includes used cooking oil and some other animal fats.

The US Department of Agriculture tracks the share of US vegetable oil production devoted to bio-based diesel, which has risen steadily and exceeded 40 percent in 2022.

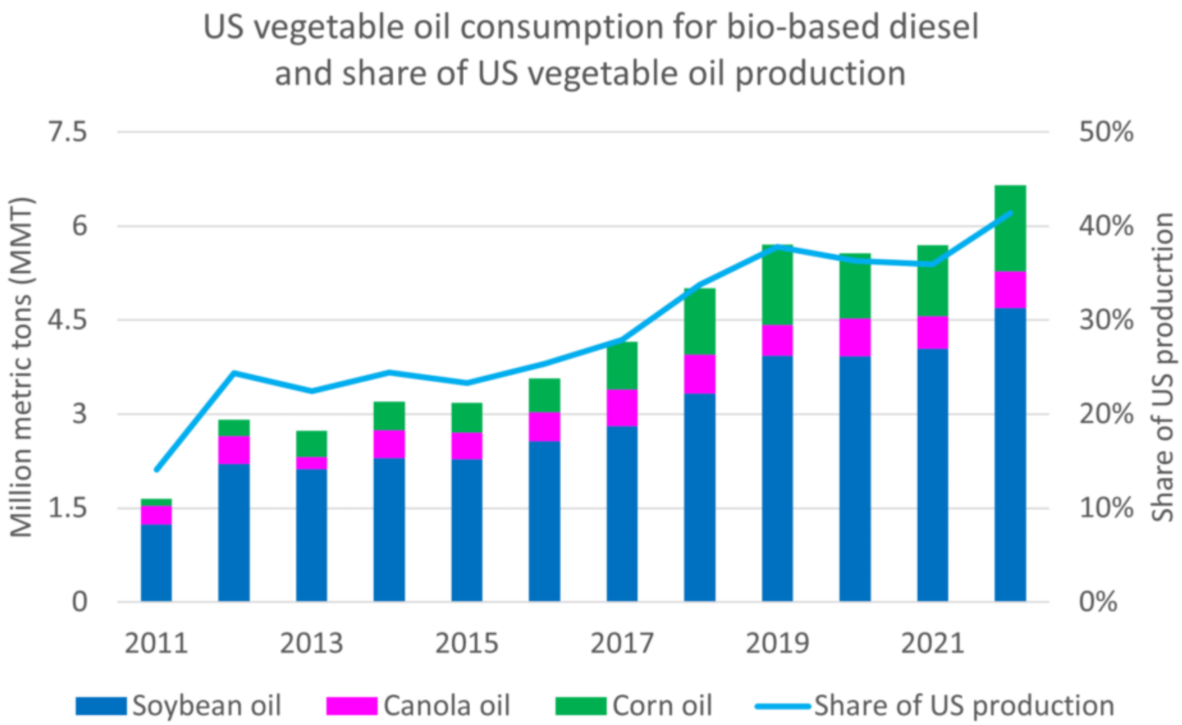

Figure 7: Use of vegetable oil to produce bio-based diesel increased more than 4 fold between 2011 and 2022 and the share of US vegetable oil production used for biofuels exceeded 40 percent in 2022. Source USDA Oil crops yearbook.

Statistics for yellow grease, tallow and other feedstocks are less well documented, so it is hard to assign a precise share, but experts agree that a large share of the available resources are now being used to produce the bio-based diesel.

The growing share of US vegetable oil used for bio-based diesel production is reflected in the balance of US trade in vegetable oil. Net vegetable oil imports grew by about 4 MMT between 2006 and 2022, especially canola oil and palm oil, which have replaced soybean oil in food uses. This has been a gradual process that reflects both changing consumer preferences and diversion of soybean oil to fuel production. More recently the US has effectively exited the export market for vegetable oil entirely and is now the 4th largest importer of vegetable oil after India, China and the European Union (USDA Foreign Agricultural Service).

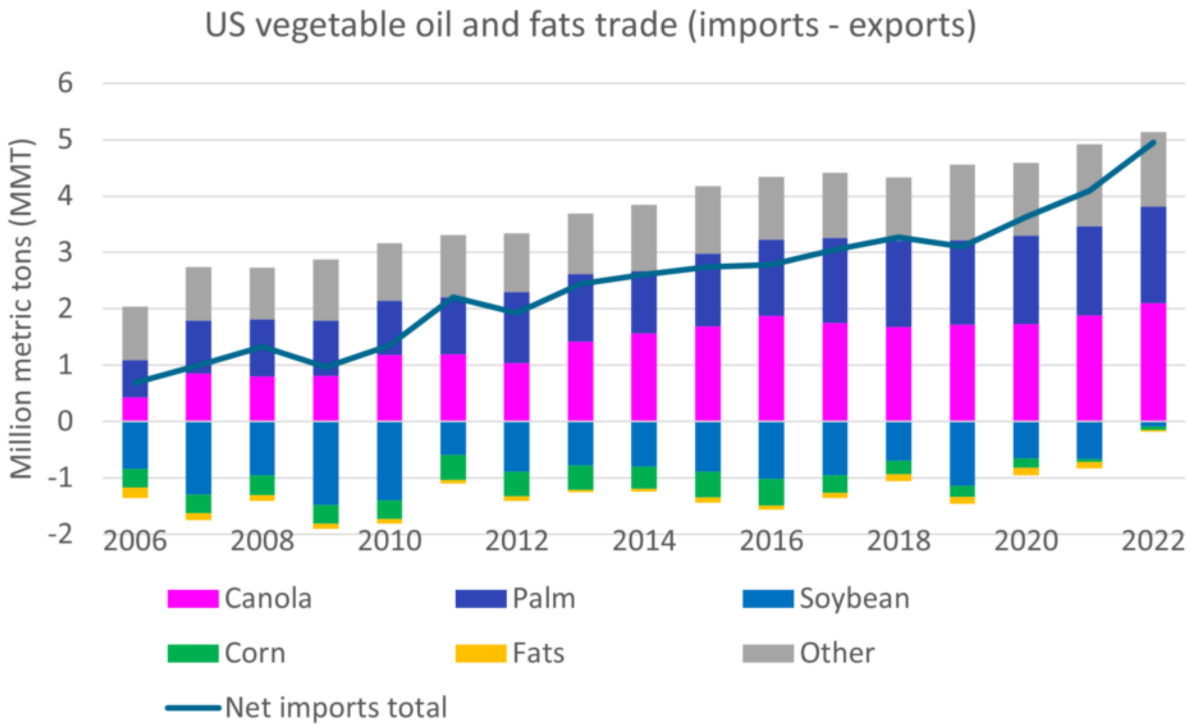

Figure 8. US vegetable oil imports have steadily risen, and exports have fallen as bio-based diesel production has climbed. Source USDA Oil Crops Yearbook.

How much feedstock is needed for future bio-based diesel production?

Scaling up bio-based diesel production requires more than production capacity; it also requires feedstock and demand. Figure 9 summarizes the quantity of feedstock that would be consumed if the planned renewable diesel facilities are built and operate at full capacity and the biodiesel industry continues to operate at its capacity as of the end of 2022. Capacity for feedstock consumption could rise by 10 to 20 MMT a year, or even more, a massive increase compared to the 11 MMT of actual US consumption in 2022. Declining production of biodiesel could potentially free up some feedstock for renewable diesel production, but since only 6 MMT of feedstock was used for biodiesel in 2022, even completely shutting down biodiesel production would free up just half of the feedstock required by renewable diesel capacity expansion announced for 2023 and 2024.

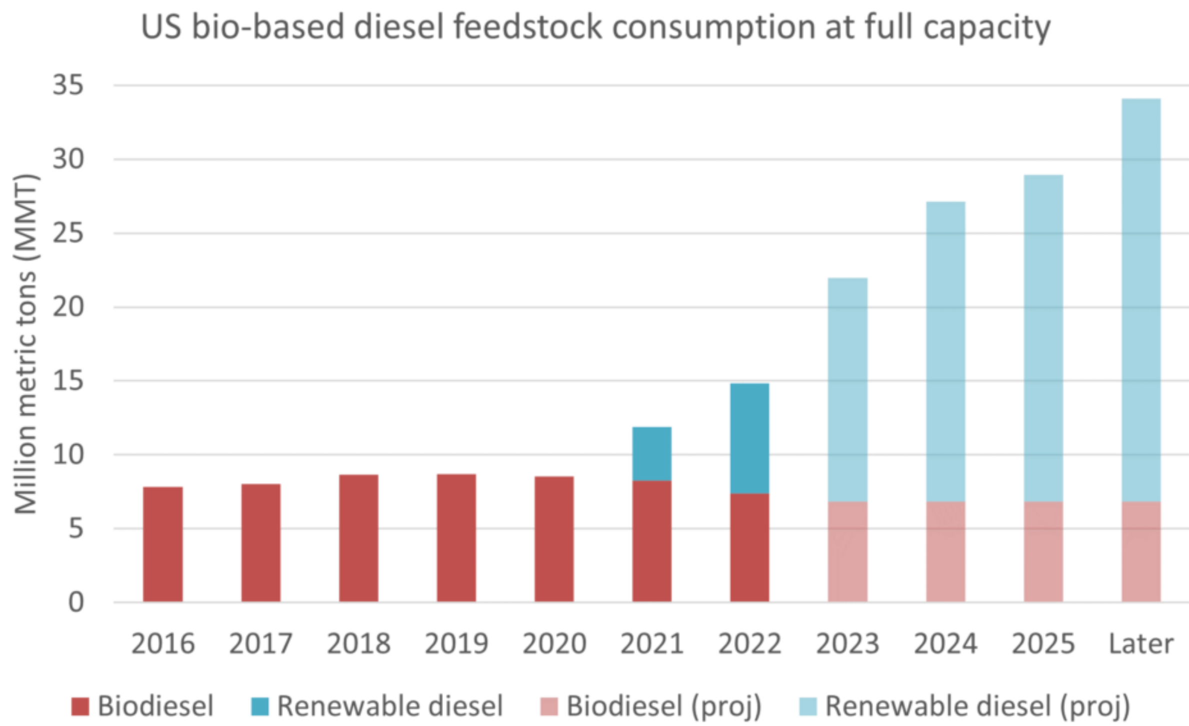

Figure 9: Combining current and announced renewable diesel production capacity and existing biodiesel production capacity, total feedstock consumption at full capacity could reach 34 MMT in the next few years. Source Energy Information Administration and farmdoc daily, March 29, 2023.

Where could an additional 10-20 MMT of feedstock come from?

The scale of demand for vegetable oil required to operate planned renewable diesel capacity is so large that meeting it would require dramatic changes to global markets for oils and fats with major implications for food consumers around the world and tropical deforestation. The bottom line is that palm oil is the only source of vegetable oil that could plausibly scale up to provide 10-20 MMT of additional vegetable oil in the next few years. Since palm oil is not an eligible feedstock for US biofuel production, other sources of oil, especially soybean oil, would most likely be diverted from food to fuel, while palm oil backfilled the soybean oil. It may seem absurd to even discuss increases this large, but analysis commissioned by a trade association for the renewal diesel industry argued recently that US feedstock for bio-based diesel could rise to 32 MMT in 2030, primarily from soybean oil.

A detailed explanation is provided in the appendix, but the main points are summarized below. Figure 10 shows global vegetable oil production in 2022.

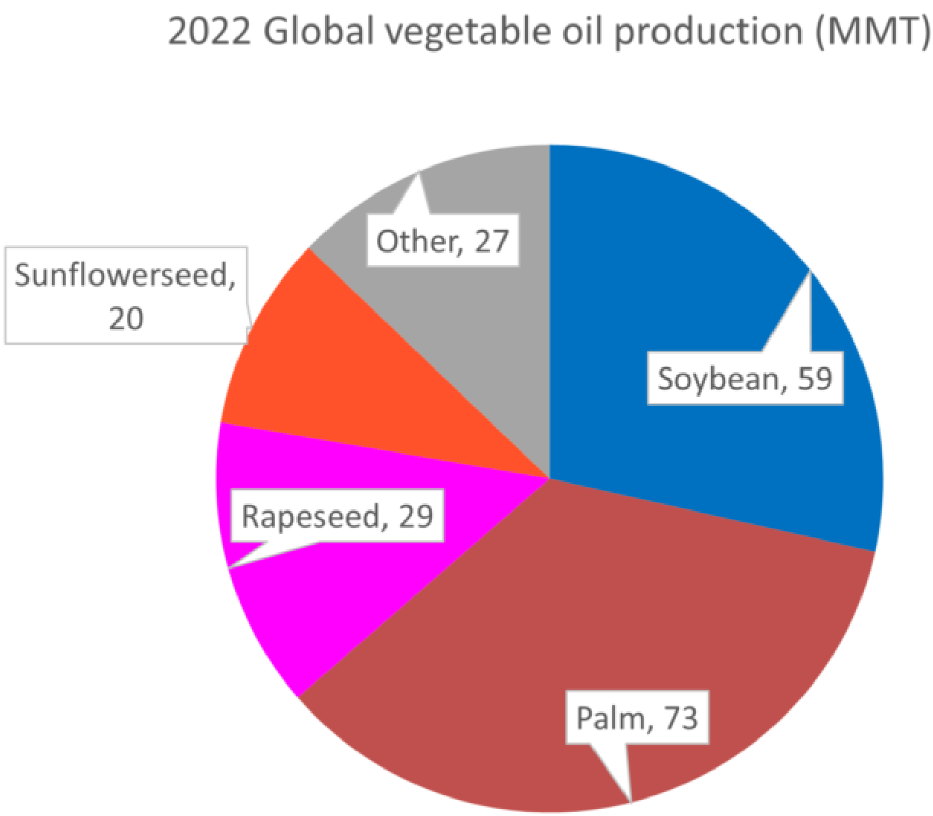

Figure 10: Global vegetable oil production in 2022 totaled 208 MMT of which palm oil accounted for 35 percent and soybean oil 29 percent. Source USDA Foreign Agricultural Service Oilseeds: World Markets and Trade.

Soybean oil accounts for three quarters of US vegetable oil production, and 29% of global production. and is the most plausible sources of supply for large increases in domestic production. To secure millions of metric tons of additional soybean oil, the US would need to reduce exports of whole soybeans and start importing soybean oil from Argentina and Brazil. If US oil companies are willing to outbid all other consumers, they could theoretically secure 10-20 MMT of additional RFS eligible feedstock. The bidding war would pit US oil companies against people's food consumption. Over the longer term, oil crop cultivation would catch up with demand and stabilize prices. But because soybean oil is a joint product with soybean meal, it is not economic to expand soybean production faster than demand for soy meal as animal feed. Thus, the additional vegetable oil required to replace the soybean oil used for fuel will mostly come from palm oil, which together with soybean oil made up 64 percent of global vegetable oil production in 2022. Domestic production and imports of other oil crops like canola/rapeseed and increased imports of used cooking oil from around the globe can contribute a small amount. But at the scale of the biodiesel boom there is no plausible source of feedstock other than soybean oil backfilled in cost sensitive food markets by palm oil.

Advice to policymakers

The idea that oil refineries can keep humming along by replacing petroleum diesel with vegetable oil or used cooking oil is a dangerous illusion. Having US oil companies backed up by billions of dollars in direct and indirect subsidies compete on the global market for vegetable oil to make into fuel is an expensive dead-end that does not support investment in scalable low carbon technology but drives up food prices and ultimately serves mostly to expand the cultivation of palm oil to replace the soybean and other oils made into fuel.

When policymakers subsidize new technologies, the justification is often the potential that scaling up a new technology will lead to cost reductions over time. But producing soybean oil and refining it at existing oil refineries is not catalyzing any fundamentally novel technology, so there is no reason to expect breakthroughs in cost to result. Policymakers need to pay attention to where the vegetable oil and feedstocks for bio-based diesel fuels come from. And when policies are placing an unsustainable draw on scarce resources, they need to act decisively to limit feedstock utilization at a sustainable level.

Today the renewable diesel boom in California is at risk of becoming a crisis, and policymakers at the Air Resource Board must act now to stop the massive expansion of soybean oil-based renewable diesel. California officials should ensure that California does not use more than half the US supply of feedstocks for bio-based diesel and related fuels.

A comparison with electric vehicles in instructive. In 2016, California accounted for 50 percent of the registrations of passenger car EVs in the US. Since that time, EV registrations in California have grown 540 percent, but registrations in the rest of the US have grown even faster, so the share of EV registrations in California has fallen to 37 percent (Source: Alternative Fuels Data Center). Over the same timeframe, consumption of renewable diesel in California has grown almost as fast as EV registrations, up 440 percent between 2016 and 2022. But where early action by California policymakers led to reduced cost and increased availability of EVs elsewhere, California's appetite for bio-based diesel feedstocks led to a decline of bio-based diesel consumption in the rest of the United States, with US consumption of bio-based diesel outside of California falling 19 percent between 2016 and 2022. The biodiesel boom is increasing costs and decreasing availability of renewable diesel and biodiesel in the rest of the United States and if the boom in California is not contained, it will lead to disruptions of global vegetable oil markets and accelerate tropical deforestation. More details on UCS's proposals to reform the Low Carbon Fuel Standard can be found here.

Ultimately, excessive utilization of any source of biofuel can become a problem if exploited at an unsustainable level. Biofuels can play a productive role if the crops used to produce them are grown without displacing food production or expanding the footprint of agriculture onto sensitive ecosystems. Policymakers need to be realistic about where biofuels come from, and limit feedstocks to a sustainable scale to avoid sending our fuel policies down a damaging dead-end road.

Appendix: Where could an additional 10-20 million metric tons of vegetable oil to produce bio-based diesel come from?

Soybean oil

Soybean oil is the natural place to start a search for additional US bio-based feedstock, since it accounts for 70 percent of US vegetable oil production and is the only domestic feedstock that could plausibly scale up by several MMT in a few years' time. As shown in Figure 1 below, the US produced almost 12 MMT of soybean oil in 2022, or which 4.7 MMT was used for bio-based diesel production.

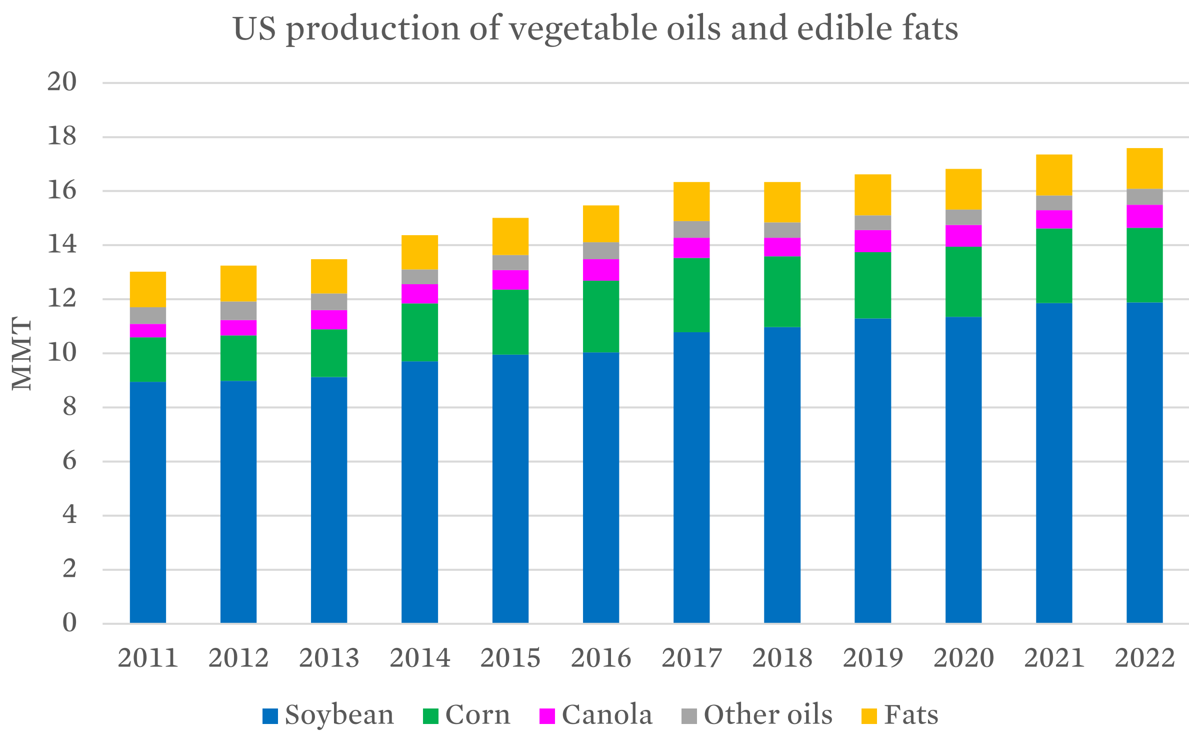

Figure A1. Soybean oil is the largest source of vegetable oil. Source USDA Economic Research Service Oil Crops Yearbook.

As shown in Figure 8, between 2006 and 2010 the US exported between 0.8 and 1.5 MMT of soybean oil, but has recently stopped exporting soybean oil and is projected by USDA to become a net importer of soybean oil in marketing year 2023/2024 (USDA ERS).

But US soybean oil production tells only part of the story since the US is a major exporter of whole soybeans. The soybeans exported by the US are processed, or crushed, in the importing countries into soybean oil and protein meal, used for animal feed. In recent decades the US has exported between a third and a half of the soybeans it produces, about 2 billion bushels in recent years. Crushing an additional 2 billion bushels of soybeans in the US would yield about 10.7 MMT of oil, or enough to produce 2.9 billion gallons of renewable diesel. Combining this with the soybean oil the US produced in 2022 leads to a total of over 22 MMT. Since only 5 MMT of soybean oil was used for fuel in 2022, the

US could more than double bio-based diesel production by redirecting US soybeans away from existing markets for vegetable oil and whole soybeans.

The idea that the US should scale up domestic production of bio-based diesel by crushing all of US soybeans for fuel production is effectively the argument made by the Advanced Biofuels Association backed up by an analysis suggesting that [US feedstock for bio-based diesel could rise to 32 MMT in 2030, primarily from soybean oil]. However, idea that the US could crush all of its soybeans ignores the practical barriers to crushing more soybeans and the more profound consequences of changes in global markets for food and agricultural commodities as the US redirects food into fuel markets.

Crushing more US soybeans

In the last few years, as renewable diesel producers made plans to increase production, so did the soybean crushing industry. Some of these were partnerships, such as the Marathon Petroleum partnership with [ADM in North Dakota]. By the end of the 2022, 23 [new facilities or expansions had been announced totaling 750 million bushels a year of new crushing capacity], equivalent to 4 MMT of soybean oil, which would increase US crushing capacity by 34 percent if they were all completed as planned.

Dramatically increasing US soybean crushing for domestic biofuel production has complex and uncertain implications for three commodities: (fuel, vegetable oil and meat) especially in three regions of the world (North America, South American and Asia).

Soybean economics

Soybeans are an interesting crop, connected to their sister crop corn in complex ways in the agriculture, food and fuel system. While you may occasionally encounter soybeans in their immature form as edamame, the majority of soybeans are crushed to make soybean oil and a high protein meal that is mixed with corn in animal feed.

Historically, soybean meal has been the more valuable product of soybean crushing, often worth twice as much as the oil. The economics of soybean production depend jointly on the oil and the meal. As you would expect, increased demand for soybean biodiesel will raise demand and prices for soybean oil, but meal goes the other direction. As more soybeans are crushed to supply oil, the price of soybean meal will fall as increased production meets unchanged demand.

Since soybean prices depend on the sum of oil and meal prices, the net result is that soybean prices are only weakly linked to soybean oil prices. In a specific example worked out and explained in [this analysis prepared by a Professor at Purdue University for the United Soybean Board], a 20 percent increase (0.84 MMT) in the use of US soybean oil for fuel led to an 8.2 percent increase in soybean oil prices, a 1.9 percent decrease in soybean meal prices and a 0.7 percent increase in soybean prices. The study also estimated changes in food prices, predicting a 4.4 percent in retail vegetable oil prices and much smaller decreases in the retail prices of eggs (0.16 percent), poultry (0.13 percent) and other animal products that benefit from reduced feed prices.

The consequence of all of this is that using more US soybean oil for fuel is expected to have a very small (0.2 percent) impact on US soybean production because meal prices that move the other direction will reduce the economic incentive to increase soybean production. The larger impacts occur overseas as the US trade patterns shift, with the US exporting fewer soybeans and increase net imports of vegetable oil, including not just soybean oil but also other oils that replace soybean oil.

Global consequences of increasing US soybean oil-based fuel production

There are three plausible consequences of increasing US production of soybean oil-based fuel: people eat less vegetable oil, soybean cultivation in increased or increased cultivation of other oils backfills the soybean oil used for fuel.

Decreased consumption of soybean oil for food

In the short term, higher prices for soybean oil prices lead to decreased consumption. Over the last few years, high prices for vegetable oil have been a major contributor to the food crisis**.** According to the food price index of the Food and Agriculture Organization of the United Nations, the vegetable oil price index reached 188 (versus 100 for 2014-2016), and was the leading contributor to a food price index that peaked at 144 overall in 2022. Biofuel policies were certainly not the primary contributor to these price spikes. But in an article from the International Food Policy Research Institute titled Food versus Fuel v2.0: Biofuel policies and the current food crisis, Joseph Glauber (former Chief Economist of USDA) and Charlotte Hebebrand showed that on a global basis, 15 percent of vegetable oils are now used for fuel production and while some countries temporarily reduced biofuel production in light of vegetable oil shortages, US consumption of vegetable oil for fuel rose steadily throughout the crisis. Prices, although still elevated, came down in 2023, and over time increased production will presumably stabilize prices.

It is important to remember that feedstocks for fuel are also food, and in a bidding war for vegetable oil, the lowest income food consumers are most likely to lose out. The previously cited study on the impact of increased use of soybean oil for fuel found that "a 20% increase in quantity of soybean oil demanded for use in biofuels increases the food-at-home component of the [Consumer Price Index] by only 0.05%." This very small impact on US consumers reflects that increased vegetable oil prices are partly offset by decreased prices for animal products, but mostly that agricultural commodity prices are a small share of US retail food prices. These mitigating factors are less relevant for the lowest income global consumers, who eat less animal protein and spend a much higher share of their food budget on basic commodities like vegetable oil.

Increased cultivation of soybeans outside the US

For reasons discussed above, increased US consumption of soybean oil for fuel will have a very modest impact on US production of soybeans but a larger impact in soybean exports. In the previously cited study, a 20% in US soybean oil consumption for fuel led to a 0.2 percent increase in US soybean production, but a much larger 1.1 percent decrease in US soybean exports.

The US and Brazil are the two largest global soybean producers, accounting for more than 70 percent of the global soybean production in 2022 between them, so reduced exports from the US are likely to be replaced by Brazil. China is by far the largest importer of soybeans, accounting for 68 percent of imports in 2022.

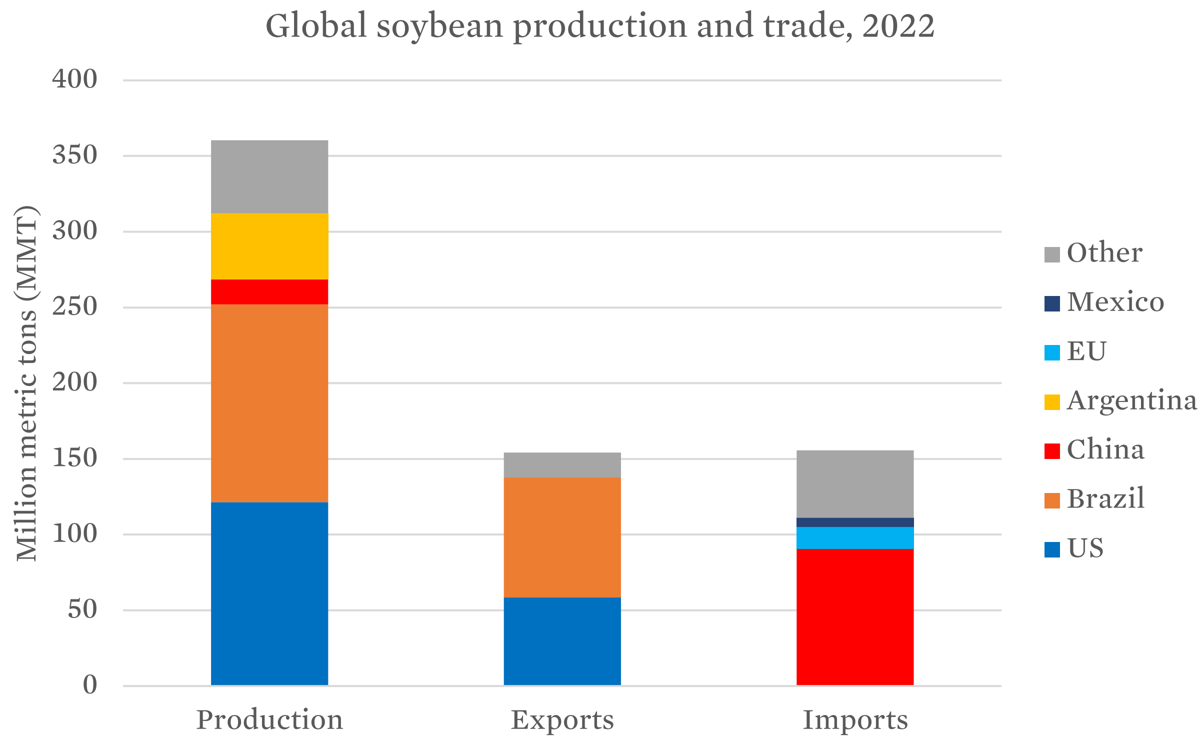

Figure A2: Source USDA Foreign Agricultural Service Oilseeds: World Markets and Trade.

Soybean production has grown rapidly in Brazil, and Brazil recently surpassed the US to become the world's leading producer and exporter of soybeans. Both increased acreage and increased yields have contributed to Brazil's increased soybean production, with acreage increasing 50 percent in the last decade, versus a 20 percent increase in yield (USDA FAS). Thus, increased cultivation of soybeans in Brazil contributes to the rapidly growing footprint of land used for soybean production, which is linked to deforestation and other damaging land use changes.

Soybean production around the world will likely continue to grow both through increases in yield and expanded acreage. But, as discussed previously, the growth of soybean cultivation will ultimately be limited by demand for soybean meal. If demand for soybean oil for both food and fuel uses outstrips demand for soybean meal, it will depress meal prices and mitigate demand for soybeans. For this reason, other oils will play a large role filling the gap left by diversion of soybean oil into fuel markets.

Increased US imports of vegetable oil

Because bio-based diesel is consuming an increasing share of US vegetable oil production, the US has also increased imports and decreased exports of vegetable oil. As shown in Figure 8, the US has increased imports of palm and canola oil, and decreased exports of soybean and corn oil. The net change since 2006 has been about 4 MMT. In the case of reduced exports of soybean and corn oil, trade was directly affected by use of these oils for fuel production, imported canola oil is used for both food and biofuel production, while imported palm oil replaced soybean oil diverted from food markets into fuel production.

Because of rising oil imports, the US is now the 4th largest vegetable oil importer in the world, after India, China and the European Union, and ahead of Pakistan. Notably, while the US and EU use 40 percent or more of their vegetable oil for fuel production, India and China consume more than 90 percent of vegetable oil as food (USDA FAS).

Notwithstanding common rhetoric describing biofuels as about home-grown fuels, it is increasingly clear that a growing share of the feedstock for new renewable diesel production will come from outside the US. A recent analysis from the USDA Economic Research Service on U.S. Biofuel Policies Impact on Vegetable Oil Trade concluded:

> *This structural shift in the U.S. vegetable oils market is likely to continue to affect trade flows moving forward as biofuel use continues to grow. With lower exportable supplies, the United States' key trading partners are likely to continue to shift to other markets, decrease usage, or seek other oils to fill the gaps. The strong domestic demand for vegetable oils is also forecast to continue increasing imports of vegetable oils. This is projected to push the United States to be a net importer of soybean oil in MY 2023/24.*

This analysis of national trends is reinforced by a recent LCFS pathway application Phillips 66 files with the California Air Resources Board for renewable diesel made from soybean oil from Argentina. In light of the trends discussed above, it is not be surprising that fuel producers are looking overseas, especially given the scale of oil required for a facility of this size. Running at full capacity, the Phillips 66 Rodeo facility would consume 2.5 MMT of feedstock a year. The Phillips 66 Rodeo facility presumably has the necessary logistics to unload oil directly from tanker ships coming from the Pacific Ocean. And Argentina is the world's largest exporter of soybean oil, exporting 4-6 MMT of soybean oil in recent years out of a total production of 6-8 MMT. This one huge facility could potentially consume about half Argentina's exports.

Total global soybean oil exports from all countries have been around 12 MMT in recent years, so increasing US soybean oil imports by several MMT could have a major impact on global vegetable oil trade, pushing current importers to reduce consumption and switch to palm and other vegetable oils. Argentina and Brazil are the largest exporter of soybean oi, and India is the largest importer. However, most soybeans are crushed in the country that consumes the oil, so a more complete comparison is between the countries where soybeans are grown to the countries where soybean oil is consumed. Soybean production is dominated by Brazil, the United States and Argentina, which account for 36, 34 and 12 percent respectively in 2022. China, the United States, Brazil and India were the largest soybean oil consumers, accounting for 28, 19, 13 and 10 percent respectively.

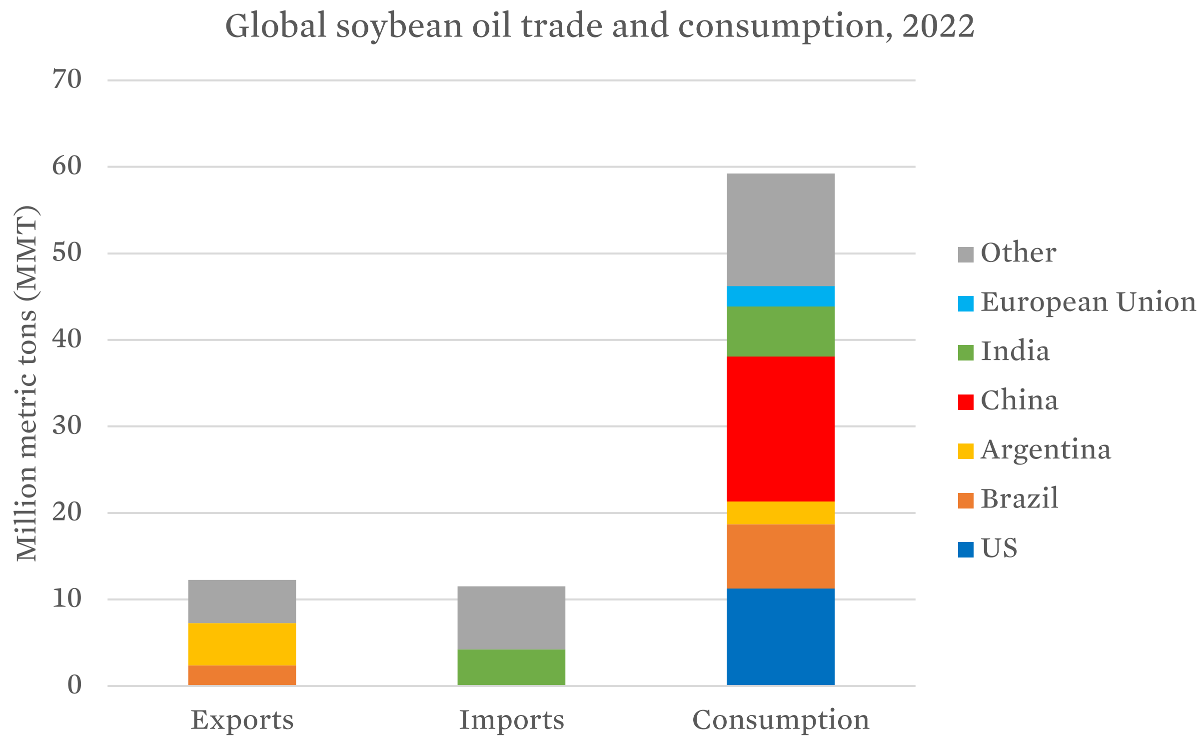

Figure A3: Source USDA Foreign Agricultural Service [Oilseeds: World Markets and Trade](#).

Other vegetable oils.

If US oil consumption of soybean oil for fuel increases faster than global demand for protein meal, it will create an imbalance in global markets for soybean oil and soybean meal. The way to rebalance these markets is to shift a larger share of vegetable oil production toward crops that produce more oil relative to meal. Of the major global oil crops, palm, canola and sunflowers produce a higher share of oil than soybeans. Corn oil is mostly a byproduct of ethanol production that is already almost fully utilized for bio-based diesel production, so it is not a plausible replacement for soybean oil.

Canola oil

Canola oil is the third largest source of vegetable oil produced in the US after soybean oil and corn oil. However, canola oil has a significantly higher yield of oil relative to protein meal compared to soybeans, so increasing cultivation of canola relative to soybeans can shift the balance of oilseed production in favor of oil. In 2022 Canola accounted for less than 1 MMT or about 5 percent of US vegetable oil production. So increased domestic production is likely to have a modest effect on US vegetable oil production in the near term. Globally canola/rapeseed oil accounts for 15 percent of vegetable oil production, and the US imported more than 2 MMT of canola oil in 2022. So canola oil imports are likely to play a larger role in the near term.

Longer term there are other promising oils crops in development, including camelina, winter hardy oilseeds and energy crops bred for high oil content. These crops have potential ecological advantages including improving water quality in addition to potentially significant vegetable oil production. But it will take time to develop and scale up these new crops, so they are not likely to supply millions of metric tons of oil in the next few years. Longer term these novel crops could be a potentially more significant source of increased US vegetable oil production.

Palm oil

Palm oil looms large over the vegetable oil debate because rapidly expanding palm oil cultivation in Indonesia and Malaysia has often come at the expense of draining peat forests, leading to major carbon emissions and other environmental and human rights harms. For this reason, palm oil is not an eligible feedstock for bio-based diesel fuel production under the federal RFS, and the California LCFS assigns land use change emissions to palm oil biodiesel that are 1.5 times higher than soybean oil biodiesel and 3.6 times higher than corn ethanol. Thus, it is very unlikely that palm oil is used to produce bio-based diesel in the US.

However, while palm oil won't be used directly to produce US biofuel, it is likely to play a primary role in replacing the soybean oil that is diverted from food markets to fuel production. As shown in Figure 8, palm oil and canola oil imports to the US have grown as soybean oil has increasingly been redirected to fuel production. But a potentially more significant shift is possible in global markets, particularly in Asia.

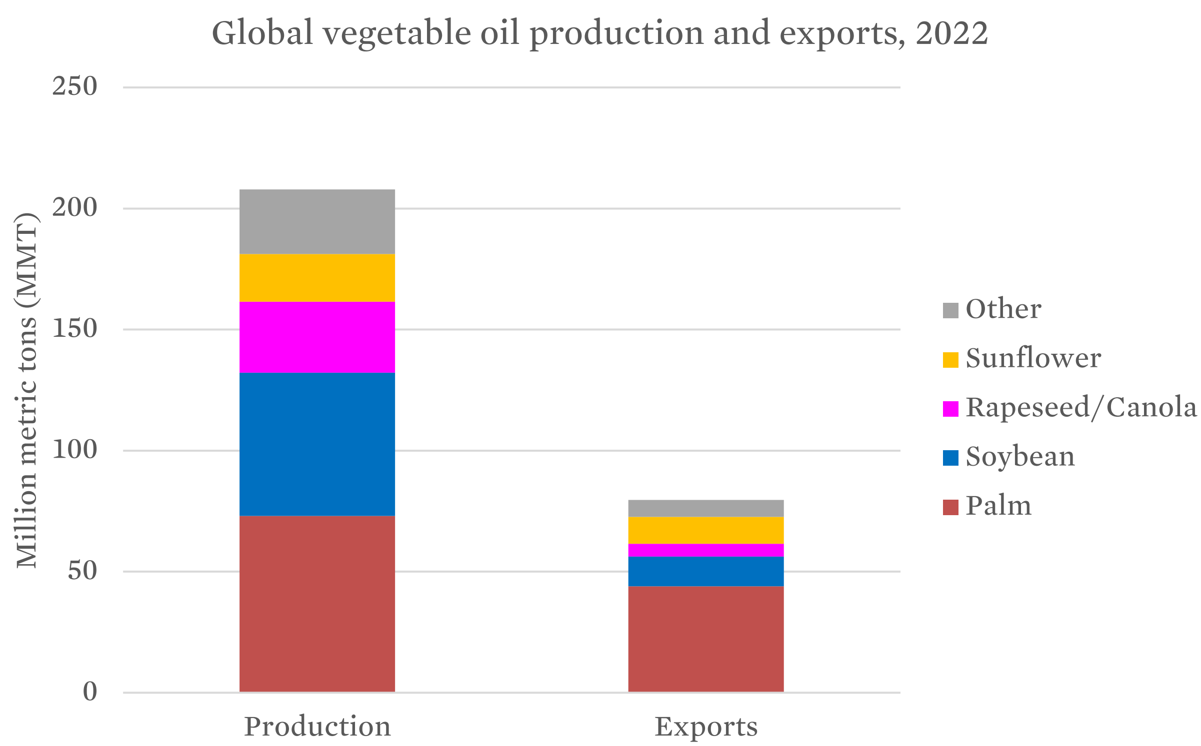

Figure A4: Source USDA Foreign Agricultural Service Oilseeds: World Markets and Trade.

Palm oil is the largest and fastest growing source of vegetable oil in the world, accounting for 35 percent of global vegetable oil production and 55 percent of global trade in vegetable oil in 2022, and is less expensive than many other vegetable oils. And while soybean oil production responds weakly to demand because it is produced jointly with soy meal, palm oil is the primary product of oil palm production, and thus much more responsive to increased demand for vegetable oil. For all these reasons, palm oil is likely to be the primary replacement for soybean oil that is diverted from global markets.

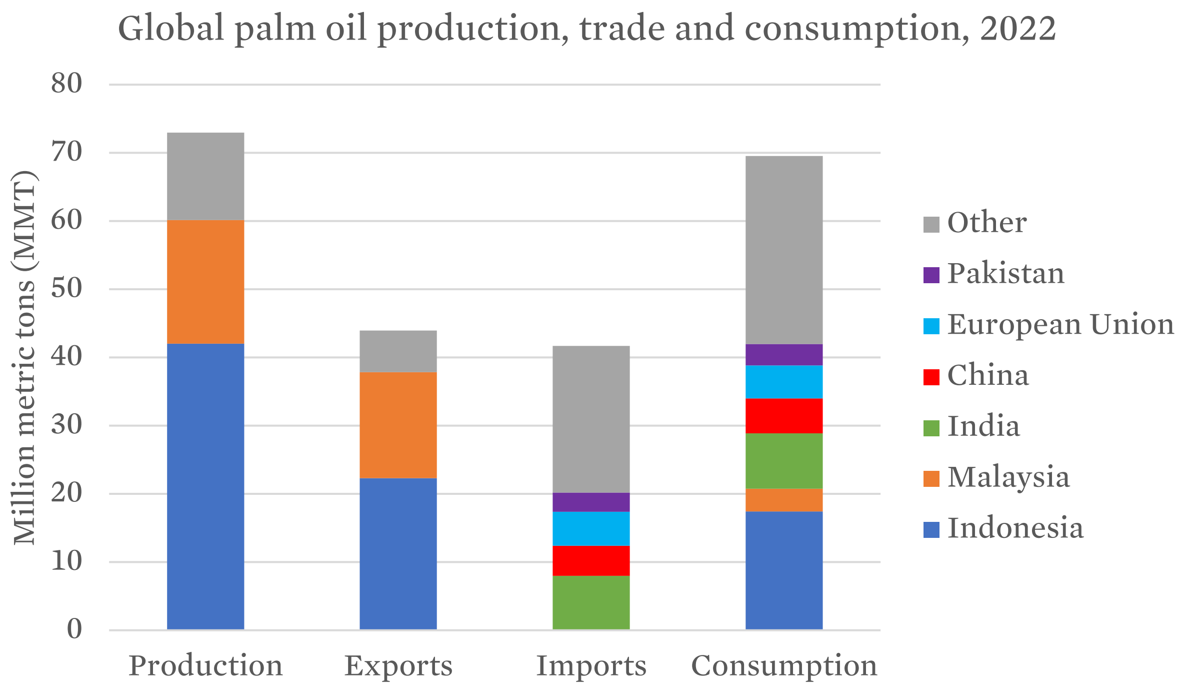

Figure A5: Source USDA Foreign Agricultural Service [Oilseeds: World Markets and Trade](#).

More than 80 percent of palm oil is produced in Indonesia and Malaysia, and India, China and the European Union are the largest palm oil importers. If the US starts importing a more soybean oil from global markets for fuel production, cost sensitive consumers in these and other countries will accelerate their shift toward less expensive palm oil. Additionally, if the US reduces its exports of whole soybeans and expands exports of soybean meal while using the oil for fuel production, China and other countries currently importing whole soybeans will need to find a replacement for the soybean oil they would have crushed domestically, further increasing consumption of palm oil.

Yellow grease and other secondary fats and oils

California's LCFS policy (and related policies in Oregon and Washington) include a substantial preference for fuels produced from secondary fats and oils, including used cooking oil, inedible distillers corn oil, and animal fats. At an LCFS credit price of $100 per ton of avoided CO2 This incentive is worth $0.25 – 0.75/gallon for renewable diesel made from yellow grease instead of soybean oil depending on the LCFS credit price[5]. The justification for this incentive is that consumption of these feedstocks will not expand the cultivation of crops, and thus not contribute to land use change. Because of these policy preferences, fuel producers making bio-based diesel fuel for these markets have a substantial incentive to use these feedstocks. Marathon Petroleum recently entered into a joint venture with Neste, an oil company from Finland, to supply used cooking oil and other feedstocks to the converted oil refinery in

[5] Calculated at credit prices of $66 and $200 per LCFS credit. Each credit represents one metric ton of carbon dioxide equivalent pollution below the standard.

Martinez California. Across the country in Louisiana, [Diamond Green filed an LCFS pathway application] that shows it plans to produce renewable diesel for California sourced from used cooking oil and animal fats from South America, Asia and Oceana.

While expanding fuel production without expanding crop production seems like free lunch of sorts, reality is not that simple. First, there is a very limited supply of secondary fats and oils, and the available supply in the US is almost fully utilized. That's why imports from around the world feature so prominently in the plans of the big renewable diesel producers. The generous incentives for recycled oils also create an increased risk of fraud. If palm oil is successfully passed off as used cooking oil, it would not only avoid the prohibitions and penalties associated with palm oil-based biofuel, it would receive the favorable treatment reserved for secondary fats and oils.

Moreover, the assumption that secondary fats and oils have no impact on crop production is an oversimplified view of these resources. Very little of the secondary fats and oils were truly a waste product but are instead used for animal feed or to produce soaps and detergents. Just as consumers of soybean oil can substitute other oils, current users of secondary fats and oils will switch to other resources if secondary fats and oils are expansive or unavailable. Used cooking oil and distillers corn oil are also used for animal feed. As these sources of oil are diverted to fuel production, the oil calories in feed are replaced by other sources of calories as animal feeds are reformulated to reflect the cost and availability of inputs.

The point is that even secondary fats and oils are no free lunch. There is a limited supply of used cooking or animal fat, and increasing demand for these in fuel markets will displace existing users of these products. So it is important to be realistic about available supply of secondary fats and oils and the impact of diverting them from existing uses to fuel production.

Attachment 2. A Cap on Vegetable Oil-Based Fuels Will Stabilize and Strengthen California's Low Carbon Fuel Standard

January 30, 2024. Available online at https://blog.ucsusa.org/jeremy-martin/a-cap-on-vegetable-oil-based-fuels-will-stabilize-and-strengthen-californias-low-carbon-fuel-standard/

I have long been a supporter of California's Low Carbon Fuel Standard (LCFS). The LCFS is the leading example of a Clean Fuel Standard, an approach to transportation fuel policy that holds oil refiners accountable to reduce the carbon intensity (CI) of transportation fuels. The CI is determined through a lifecycle analysis of the global warming pollution associated with the production and use of gasoline, diesel, biofuels, electricity, or other alternative fuels. Oil refiners comply with the LCFS by blending cleaner alternative fuels into the gasoline and diesel they sell, and also by buying credits generated by vehicles that don't use any gasoline or diesel at all, such as electric vehicles (EVs). The LCFS has delivered important benefits to California, including billions of dollars of support for transportation electrification, and has been a model for other states. Oregon and Washington have enacted similar policies, and Minnesota, Illinois, Michigan, New York, and New Mexico have taken up legislation to adopt similar policies. Federal transportation fuel policy would also benefit from a more comprehensive approach that supports electricity, among other alternatives to petroleum and focuses on emissions reductions rather than simply requiring the use of increased volumes of biofuels.

But California's LCFS has been struggling and is approaching a treacherous precipice. A flood of credits from renewable diesel and manure biomethane have depressed credit prices, undermining the support the LCFS provides for electrification and more scalable low carbon fuels. A rulemaking process is underway to amend the rules of the LCFS including updating the scheduled increases in stringency. The current rules require a 20 percent reduction in the CI of transportation fuels by 2030, which the proposed amendments would change to 30 percent in 2030 and 90 percent in 2045. The California Air Resources Board (CARB) is set to consider the proposed changes on March 21.

Getting this right is important, both for California and to ensure the LCFS remains a workable model for other states and the federal government. When the Board meets in March to update the LCFS, they should place a cap on vegetable-oil based fuels for four major reasons:

1. **Broken policies:** Counter-productive interactions of the LCFS with federal policy are leading oil companies to redirect most of the bio-based diesel (biodiesel and renewable diesel) they are required to sell in the United States to California, which now consumes more than half of the national supply, even though California consumes only 7 percent of the nation's overall diesel fuel (bio-based and fossil diesel combined). This is drawing bio-based diesel fuel out of other states and putting California and federal fuel policies into a vicious cycle that is contributing to ever more unsustainable and expensive fuel policies.
2. **Global hunger and deforestation:** Excessive consumption of bio-based diesel fuels has already contributed to the 2022 global food crisis, and is accelerating deforestation caused by increased soybean and palm oil cultivation around the world.
3. **Gas prices:** Without a cap, the flood of bio-based diesel into California will continue, requiring a rapid increase in stringency to stabilize LCFS credit markets, sending 2030 stringency from the 30 percent proposed in the regulation to 34.5 percent or even 39 percent with a commensurate increase in costs for California drivers.

4. **Credit price stabilization and support for EVs:** Limiting the use of vegetable oil-based biofuels, as CARB staff considered in a proposal to cap the use of fuels made from virgin oils, will stabilize LCFS credit markets with less dramatic increases in stringency, supporting a balanced set of clean transportation solutions, including EVs, while reducing costs for California drivers.

This post focuses on the need for a cap on vegetable oil-based fuels, which is one of several necessary reforms to the LCFS. For more information on our position on manure biomethane and other topics, see my post, "Something Stinks: California Must End Manure Biomethane Accounting Gimmicks in its Low Carbon Fuel Standard."

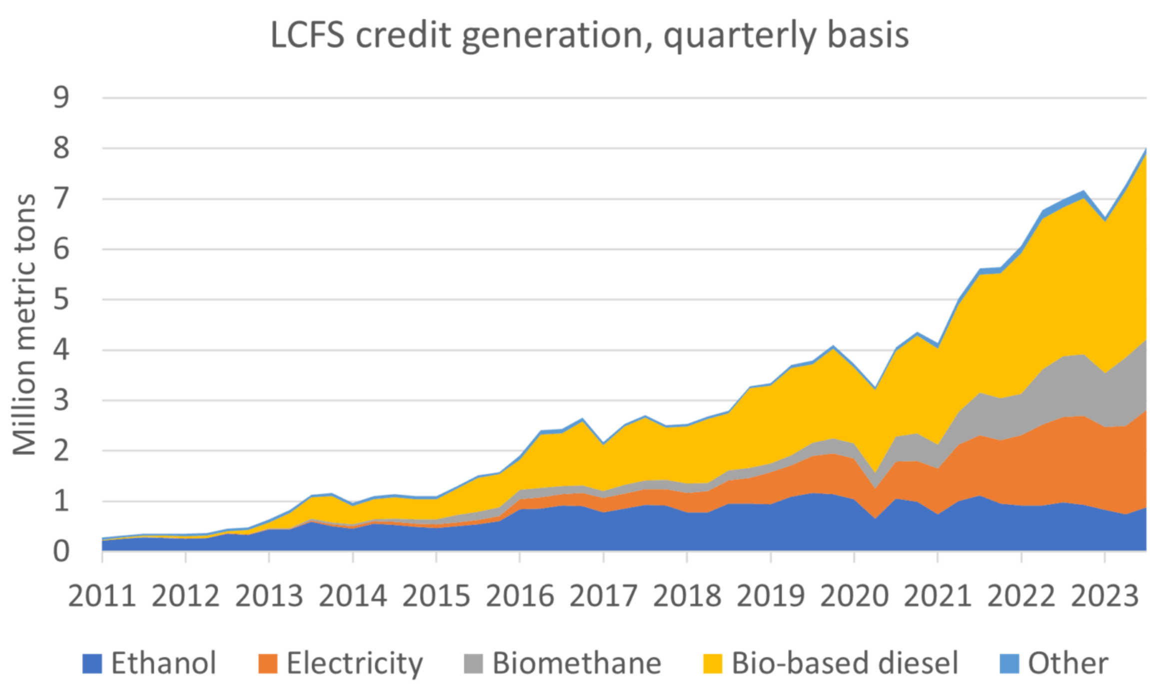

Figure 1. LCFS credit generation. Source California Air Resources Board.

What broke the LCFS?

To solve a problem, it is important to understand the root causes. California's transportation fuels policy creates a market for low carbon fuels, which are tracked using a system of credits and deficits shown in Figure 1 below. The supply of credits from low carbon fuels has been exceeding the requirements of the LCFS, leading to falling credit prices. You might think that low credit prices mean the program is meeting its goals at lower cost than expected, which would be great. Unfortunately, this is far from the truth. More than 60 percent of the credits flooding the program are coming from bio-based diesel and biomethane, crowding out the support the LCFS would otherwise provide to electric cars and trucks to support California's transition away from combustion fuels.

Stabilizing credit prices at a level that supports steady progress (roughly $150 per metric ton) is a key goal of the rulemaking process. Since credit prices are set by the balance of supply and demand, prices could be raised by either restricting the supply of credits or by increasing LCFS stringency to raise demand. During the two years of workshops that preceded the formal proposal, concepts discussed by

CARB staff included changes to the rules that would reduce the supply of credits from bio-based diesel and biomethane and increased stringency to increase demand for credits. But the official proposal abandoned any meaningful effort to address supply and focuses almost entirely on increasing stringency.

CARB has proposed increasing the 2030 stringency of the LCFS by 50 percent, from the current requirement of a 20 percent reduction in the carbon intensity in 2030 to a 30 percent reduction in 2030. CARB has also proposed an auto-acceleration mechanism, which could see the 2030 stringency rise to 34.5 percent or 39 percent if the supply of credits continue to substantially exceed demand.

In my feedback over the last 2 years, I argued CARB should cap support for bio-based diesel made from vegetable oil and phase out credits for avoided methane pollution to wind down what has become, in effect, a poorly run offset program. Bio-based diesel and manure biomethane generate a lot more credits than an accurate assessment of their climate benefits would support, and are causing additional problems to boot. Unfortunately, the official proposal ignores the oversupply of low value credits and focuses almost exclusively on increasing demand by accelerating the pace of the program. This won't work—and will make the LCFS needlessly costly for California drivers, while postponing the needed reforms that would restore the stability of the LCFS. Moreover, absent reform, the LCFS is not a replicable model for other states or the federal government.

Capping the renewable diesel boom

Bio-based diesel refers to two closely related fuels, biodiesel and renewable diesel that are made from vegetable oils and animal fats and blended into diesel fuel. I just posted a detailed article describing the surge in renewable diesel—used mostly in California and made increasingly from soybean oil—that threatens to create major problems in global vegetable oil markets and accelerate tropical deforestation caused by expanding cultivation of soybeans and palm oil.

California may seem like an unlikely driver of deforestation from soybean and palm oil biofuels. The California LCFS has, since its inception, included significant disincentives for the use of crop-based biofuels, including soybean and palm oil-based diesel. Instead, the LCFS encourages the use of fuels made from used cooking oil, animal fats or other secondary fats and oils. For almost a decade, these disincentives effectively kept crop-based diesel fuels out of the California market. However, for reasons explained below, this incentive-based safeguard has become ineffective, and since 2020 California's bio-based diesel has increasingly been made from soybean oil, some of it sourced directly from South America.

The proposed amendments to the LCFS acknowledge the risks posed by the rising use of soybean oil-based renewable diesel. This reflects concerns raised by many stakeholders, myself included, at LCFS workshops since December 2021 (I submitted technical feedback on this topic six times over the last two years, and coauthored a paper on the subject). The first page of the rulemaking document suggests CARB intends to "[strengthen] guardrails on crop-based fuels to prevent deforestation or other potential adverse impacts." The proposal considers a cap on the use of fuels made from virgin vegetable oils in Alternative 1, but then rejects it based on flawed arguments addressed below. Instead of a cap, the proposal suggests tracking the chain of custody for crop-based feedstocks, an ineffective approach that will not address the root causes of the problem.

I'll explain why the cap described in Alternative 1 is the right decision, why the arguments against it are wrong, and why the feedstock tracking proposal is not an adequate safeguard. But first it's important to understand how the implementation of the LCFS is being distorted by complicated interactions with federal biofuels policy, since this explains the root cause of the renewable diesel problem and points the way to a solution.

The LCFS operates on a playing field shaped by federal policy

If the California LCFS acted without the influence of federal policy, there would be no renewable diesel boom, and there would certainly not be a flood of soybean oil-based diesel. The limited support offered by the LCFS for soybean oil-based fuels would not come close to covering the cost of expensive soybean oil needed to make the fuel. It's the interaction of the California LCFS with federal policy, particularly the Renewable Fuel Standard (RFS), that has led to California's renewable diesel boom.

The RFS requires oil companies to blend increasing amounts of a few types of biofuels into the gasoline and diesel they sell. In its early years, between 2005 and 2010, the RFS helped launch the massive scaleup of corn ethanol that established 10 percent ethanol as the de facto standard for US gasoline. After 2010, bio-based diesel fuels (biodiesel and renewable diesel) have been the main beneficiary of the RFS.

Bio-based diesel fuels are expensive. Without substantial policy support, there would be little if any bio-based diesel fuel produced or consumed in the United States. Analysis by the Environmental Protection Agency (EPA) in the most recent RFS rulemaking finds that more than 90 percent of the costs of complying with the RFS, $7 to $8 billion a year, are associated with bio-based diesel fuels[6]. These costs are spread across all the diesel fuel consumed in the United States, adding 13 to 15 cents per gallon to the cost of diesel fuel in the United States, according to EPA.

The RFS sets national targets, but also includes a system of tradable credits that allow overcompliance in one region (or by one company) to offset undercompliance in another region (or by another company). This flexibility allows for higher levels of biofuel consumption in states with supportive policies to offset lower consumption elsewhere. Economic factors and practical limits on blending keep ethanol and biodiesel widely distributed. In 2020, every state except Alaska blended at least 9.5 percent ethanol into their gasoline versus a US average of 10.3 percent, while 35 states blended at least 2 percent biodiesel into their diesel, versus a US average of 3.8 percent.

Renewable diesel is a different story. Since renewable diesel is a replacement for diesel rather than an additive, there are no practical blending constraints. This has allowed oil companies to meet a rising share of their RFS obligations in California, where the same fuel also provides compliance for the LCFS. **In 2022 half of the bio-based diesel consumed in the United States was consumed in California, which accounts for just 12 percent of US population and just 7 percent of the nation's overall diesel (bio-based and fossil diesel combined).** The factors that concentrated half of US bio-based diesel in California are only getting stronger, as more renewable diesel production capacity comes on-line in California, and California raises the targets for the LCFS.

[6] US EPA. Renewable Fuel Standard (RFS) Program: Standards for 2023–2025 and Other Changes. Regulatory Impact Analysis. Section 10.4.2, specifically table 10..4.2.2-4. Online at nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017OW2.pdf

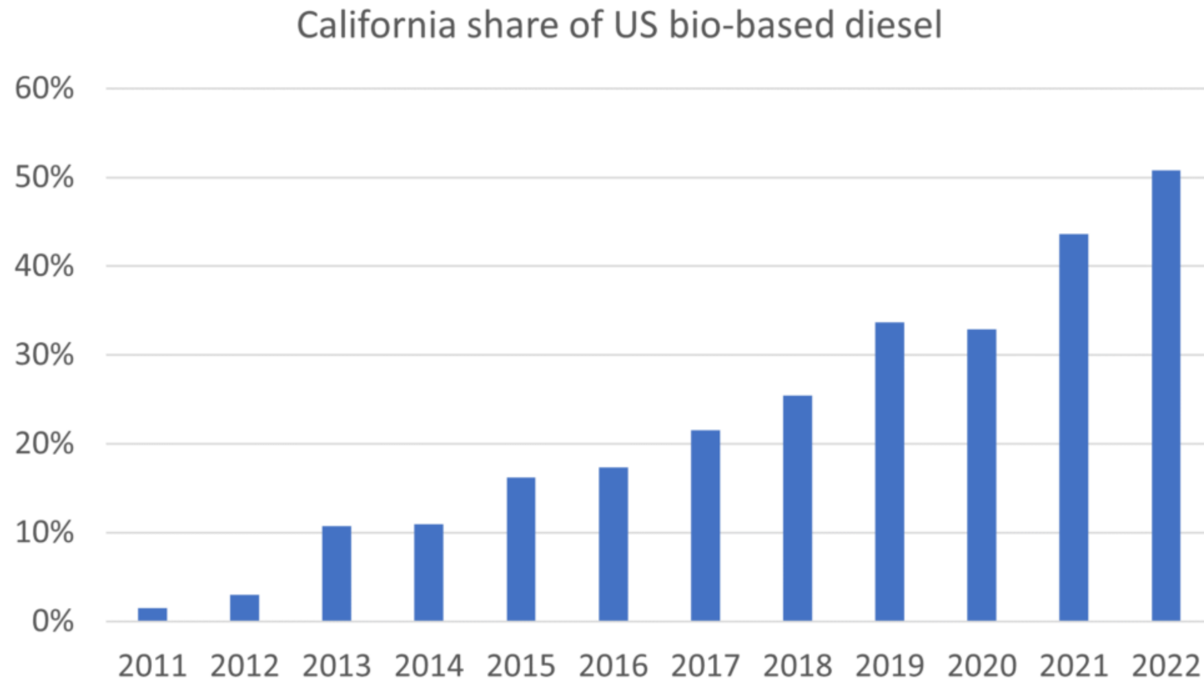

Figure 2: Share of California consumption of US bio-based diesel fuel (biodiesel and renewable diesel) weighted by their RFS compliance value. Source California Air Resources Board, US Energy Information Administration.

Unless CARB changes course, California is likely to consume well over half of US bio-based diesel, including increasing amounts of soybean oil-based fuel, putting pressure on the EPA to raise RFS targets to unsustainable levels that harm access to food and accelerate deforestation. Concentrating RFS compliance in California reduces oil companies' compliance costs, but it destabilizes both the RFS and LCFS. It makes no sense for California to consume most of the US supply of bio-based diesel.

Capping vegetable oil-based fuels is the right decision

The CARB rulemaking document called the Initial Statement of Reasons (ISOR) includes consideration of Alternative 1 on pages 88 to 102 that "includes a limit on total credits from diesel fuels or sustainable aviation fuel produced from virgin oil feedstocks." Because Alternative 1 reduces credit generation, the 2030 stringency is adjusted from 30 percent to 28 percent, but the 2045 stringency remains the same (90 percent). The lower stringency results in lower costs and reduced economic impact of the regulation. The ISOR says, "The macroeconomic impact analysis results shown in Table 23 indicate that Alternative 1 would result in more positive impacts on gross state product (GSP), personal income, employment (Figure 14), output (Figure 15) and private investment when compared to the proposed amendments." The main reasons CARB gives for rejecting Alternative 1 are the climate and air quality benefits CARB attributes to the higher use of renewable diesel. However, these apparent benefits result from faulty analysis.

According to official analysis from CARB and EPA, soybean oil-based diesel has lower lifecycle carbon emissions than fossil diesel, but this finding is quite uncertain. EPA recently conducted a model comparison exercise that found that the climate benefits attributed to soybean oil biodiesel depend entirely on which model is used to conduct the assessment. While the particular model used by CARB for the LCFS finds that soybean oil biodiesel has lower emissions than fossil diesel, other well-regarded models find that soybean oil biodiesel is more polluting than fossil diesel. But even putting aside this uncertainty, the ISOR overstates the climate benefits of using soybean oil-based fuels because it ignores the fact that use of this fuel in the United States is already mandated by the RFS, so if California uses less, another state will use more. In past rulemakings, CARB accounted for this policy overlap by only including climate benefits that exceed those required by federal law. But in the current rulemaking, CARB ignores the federal requirements, inflating the claimed climate benefits.

The inflated climate benefits attributed to renewable diesel are especially significant because California's renewable diesel boom has exhausted the supply of low-carbon sources of renewable diesel. Alternative 1 caps fuels made from virgin oils such as soybean oil, which produce few if any climate benefits not already required by the 50 percent emissions reduction requirements of the federal RFS. So Alternative 1 will have little if any real impact on global warming pollution, even putting aside the contested and uncertain benefits of soybean oil-based fuels in general.

The ISOR also attributes health benefits to increased use of renewable diesel in California, especially associated with reduced fine particulate matter, or PM2.5. This is based on a 2011 analysis and ignores a more recent 2021 study prepared for CARB that looks at the NOx and PM from biodiesel and renewable diesel used in legacy and new technology diesel engines. The key finding is that air quality benefits from older engines are not observed in new technology diesel engines, which are now required in California. This undercuts one of the main justifications offered to reject limits on renewable diesel. Ironically, because renewable diesel does offer PM and NOx emissions in older trucks that are still in use elsewhere in the US, concentrating most of US renewable diesel in California does not help Californians, but it does harm others across the United States.

Finally, the ISOR also claims that Alternative 1 has lower cost effectiveness than the proposed amendments, but this is a direct result of the inflated CO2 and health benefits. A corrected analysis would reduce or eliminate the difference in cost effectiveness.

Without a cap, things could get a lot worse

This ISOR has several deficiencies compared to previous rulemakings, starting with transparency. It is hard to understand precisely how CARB modeled Alternative 1. Based on my current understanding of the information in the proposal, it appears that the total amount of fuels made from oils and fats is projected to peak in 2025 and then to hover at roughly 2 billion gallons a year thereafter[7]. The share of bio-based diesel blend in overall diesel fuel consumption, or blend rate, is assumed to range between 44 and 56 percent through 2035, and then to increase as total diesel fuels consumption falls, as heavy-duty electrification starts to gain traction.

Reality is running well ahead of CARB projections. Bio-based diesel consumption in the first half of 2023 was at 59 percent, a level CARB modeling does not anticipate prior to 2037. I can't see any reason

[7] While there are a lot of long documents on the CARB rulemaking website, there is not a clear and quantitative description of the various alternatives, which are described inconsistently in different documents. There is no downloadable table of the quantities of fuels and credits associated with the different alternatives, or enough information to reproduce this information using the CATS tool CARB used for modelling fuel projections. In order to clarify what is at stake, I'll summarize my understanding based on the available documents. In the ISOR CARB projects that bio-based diesel will peak at 2 billion gallons in 2025, fall below 1.8 billion gallons by 2028 and then hover between 1.5 and 1.8 billion gallons thereafter. They also project several hundred million gallons of alternative jet fuel, of which half is made from virgin oils.

why bio-based diesel consumption in California would fall while renewable diesel production capacity in California is ramping up and CARB is proposing to substantially raise LCFS stringency. CARB projects total diesel consumption at 3 billion gallons or more until 2035, so actual consumption could be more than 50 percent higher than CARB's projection if bio-based diesel fully replaces fossil diesel, as a recent study from UC Davis found was 50 percent likely by 2028. If this happens, the extra credit generation beyond what is modelled in the ISOR could trigger the auto acceleration mechanism, pushing 2030 stringency to 34.5 or even 39 percent, with a commensurate increase in costs. Moreover, if all the diesel used in California is bio-based, all of the compliance costs associated with the LCFS will be borne by drivers of gasoline cars.

Alternative 1 described in the ISOR has roughly 25 percent less biobased diesel at the peak in 2025, so roughly 1.5 billion gallons. That is consistent with 2022 consumption of bio-based diesel in California, and since RFS standards are rising gradually, this would result in California consuming a little less than half of the bio-based diesel and related fuels required for RFS compliance in the United States.

The 2 billion gallons of bio-based diesel projected for the ISOR would satisfy about two-thirds of the 2025 RFS requirements, but if actual consumption exceeds the projection, California consumption could push the RFS mandate for bio-based diesel and related fuels into overcompliance. All sorts of weird things would happen if the RFS became non-binding, starting with RFS credit prices falling and the effective cost of renewable diesel available in California rising, with implications for the cost and feasibility of the LCFS[8]. A non-binding RFS is not a stable long-term situation, for both economic and political reasons. It could also create a lot of turbulence, not just in fuel markets but in food markets for vegetable oil as well.

A vicious cycle of bad fuel policy decisions

My biggest concern is that a feedback loop between California LCFS and the Federal RFS push US consumption of vegetable oil for fuel to ever more unsustainable levels. This feedback loop is influencing fuel policies today and could become a vicious cycle.

Interactions between the LCFS and the RFS have been a major contributor to the renewable diesel boom, which has flooded California with renewable diesel and depressed LCFS credit prices. Increased renewable diesel production capacity to serve the California market was one of the factors cited in EPA's decision to raise RFS standards for 2022-2025. And even with the higher RFS targets, increased renewable diesel production in and for California has at least temporarily pushed the RFS into overcompliance, sending credit prices down sharply.

If California regulators respond to low credits prices by dramatically increasing the stringency of the LCFS without a workable mechanism to avoid concentrating RFS compliance in the state, it will keep pulling a growing share of US bio-based diesel fuel into California. This puts the Midwestern biodiesel industry under pressure, and puts Midwestern soybean oil producers at a disadvantage compared to used cooking oil imported from as far away as Australia. This will create enormous political pressure on EPA to raise the RFS standards to ensure that they continue to support soybean biodiesel, renewable diesel, and growing consumption of sustainable aviation fuel in states outside of California. The resulting higher RFS standards will increase the use of vegetable oil-based fuels, driving up the cost of the RFS with uncertain climate benefits and very real risks to food markets and deforestation. Meanwhile, higher RFS standards

[8] For more on the implications of a non-binding RFS, see *Gerveni, M., T. Hubbs and S. Irwin. "Is the U.S. Renewable Fuel Standard in Danger of Going Over a RIN Cliff?" farmdoc daily (13):99, Department of Agricultural and Consumer Economics, University of Illinois at Urbana-Champaign, May 31, 2023.*

will support ever more vegetable oil-based fuel in California, further diluting the LCFS, and the vicious cycle continues.

This vicious cycle explains why raising LCFS stringency alone will not rebalance supply and demand for LCFS credits. **CARB can break this vicious cycle by limiting California's share of US bio-based diesel consumption to a reasonable level.** The proposal described in Alternative 1 to cap virgin oil-based fuels would do the job, while still leaving California as the largest consumer of bio-based diesel in the US. A cap would also leave space in the bio-based diesel market for other states that have or are considering policies like the LCFS.

As I explained in my earlier article on the renewable diesel boom, successful fuels policy in California and the United States requires being realistic about the available resources used to make biofuel. Vegetable oil is an expensive way to make biofuel with limited potential to sustainably increase scale, especially in the short term. A bidding war between the oil companies and people consuming vegetable oil for food already contributed to the recent food crisis, and may do so again. In the longer term, increased use of vegetable oil-based fuels leads to increased palm oil production to replace the soybeans diverted from food markets to make fuel, contributing to deforestation. Capping vegetable oil used for fuel at a reasonable level will encourage fuel producers to look beyond vegetable oil to more scalable feedstocks. A cap will also save California drivers money, by rebalancing supply and demand for LCFS credits without such a steep acceleration in stringency.

The guardrail proposed in the ISOR is inadequate

CARB's ISOR mentions the risks posed by crop-based fuels, but unfortunately, the proposed guardrail is inadequate. From page 32:

> CARB staff are proposing to require pathway holders to track crop-based and forestry-based feedstocks to their point of origin and require independent feedstock certification to ensure feedstocks are not contributing to impacts on other carbon stocks like forests. CARB staff are also proposing to remove palm-derived fuels from eligibility for credit generation, given that palm oil has been demonstrated to have the highest risk of being sourced from deforested areas.

Tracking the chain of custody won't work because there is more than enough soybean oil produced on existing cropland in the US, Argentina, and Brazil to produce 100 percent of California's diesel fuel. The problem with chain of custody tracking is that California won't be tracking the chain of custody of vegetable oils used to replace those diverted from global food markets for consumption in India or China.

As I mentioned in the appendix to my recent post on the renewable diesel boom, the Phillips 66 Rodeo facility is scaling up production of renewable diesel at a converted oil refinery near San Francisco. Phillips 66 filed paperwork recently indicating it plans to produce renewable diesel and other fuels using soybean oil from Argentina. At full capacity, the massive facility would consume 2.5 million metric tons (MMT) of vegetable oil a year. Argentina is the world's largest exporter of soybean oil, exporting 4-6 MMT of soybean oil in recent years out of total global soybean oil exports of about 12 MMT. This one huge facility could potentially consume about half Argentina's exports and 20 percent of global exports. To replace soybean oil from Argentina, major vegetable oil importers like India would import more soybean and palm oil that would not be subject to chain of custody tracking.

CARB has long been a leader in biofuel land use change (I served on an expert workgroup on the topic in 2010), so the staff should appreciate the complex and indirect ways demand for biofuel feedstocks can lead to deforestation. It is disappointing to see this obviously inadequate proposal in place of meaningful action to address a real problem. The proposal to remove eligibility for palm oil-based fuels is even more meaningless, given that the land use change values used in the current regulation already effectively do the same thing.

Ironically, the one place chain of custody tracking is needed is for used cooking oil, which the proposal ignores. The LCFS creates a large incentive to pass off virgin palm oil as used cooking oil. And with renewable diesel producers importing used cooking oil from around the globe, extra vigilance is merited.

Capping vegetable oil fuels and investing in alternatives to combustion

The oil industry is in transition. After a brazen display of fossil fuel industry interference at the global climate talks at COP28, it is clear that the only path to a stable climate is phasing out petroleum and other fossil fuels. Biofuels are not made from petroleum, but a realistic assessment of the available resources makes it clear that biofuels can only play a supporting role and must be limited to a sustainable scale to avoid creating more problems than they solve. Vegetable oil is expensive, its availability is limited, and expansion is linked to deforestation, so the large-scale diversion of vegetable oil to fuel production is an especially bad idea. Yet the oil industry has embraced the idea that their existing oil refineries can help solve climate change by tweaking them to process vegetable oil instead of petroleum.

Renewable diesel has recently overtaken biodiesel as the main bio-based diesel fuel used in the United States. Redirecting vegetable oil from biodiesel to renewable diesel does not reduce petroleum use or overall global warming pollution, but it does allow the oil industry to maximize the overlap in state and federal fuel regulations. The predictable next step is to move vegetable oils from renewable diesel production to jet fuel production, claiming generous tax credits while still generating RFS and LCFS credits and trumpeting an innovative new “climate solution.” Shifting the same limited supply of vegetable oil from one fuel to another will not do anything to address climate change, but it does enable misleading hype and greenwashing from the oil industry and airlines suggesting we can address climate change without phasing out combustion. Likewise, shifting more of the US supply of bio-based diesel into California won’t do anything to help the climate, but it is breaking the LCFS.

The oil industry was once the primary opponent of the LCFS, but they have found a way to work the system to their advantage. Oil companies are taking control of the bio-based diesel industry and trumpeting their plans to scale up biodiesel, renewable diesel, and sustainable aviation fuel, despite knowing there is not enough vegetable oil to make the rhetoric reality. The renewable diesel boom is partly a battle for market share as oil companies flush with fossil fuel profits fight to control the largest share of the small but symbolically important market for renewable fuels. But the collateral damage of this clash between the oil giants is not just the stability and viability of fuel policies, but food availability, deforestation, and the prices of food and transportation fuel.

California should modernize the LCFS to align with its goal of transitioning away from combustion to a zero emissions future. A sensible cap on vegetable oil-based fuels will break the vicious cycle between the RFS and the LCFS, make the LCFS less expensive and more effective, and make it easier for other states to adopt and implement LCFS-style policies. It will also help ensure the LCFS doesn’t exacerbate global hunger and deforestation. The board should send the ISOR back to staff and tell them to get this important policy back on track.

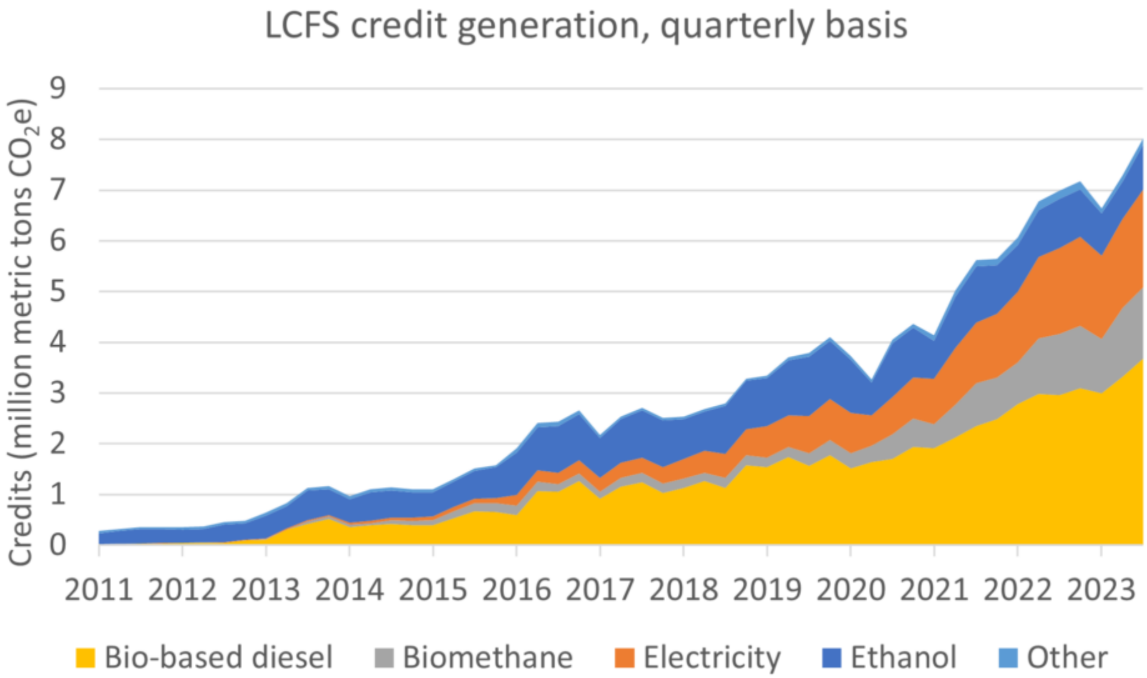
Attachment 3. Something Stinks: California Must End Manure Biomethane Accounting Gimmicks in its Low Carbon Fuel Standard

February 15, 2024. Available online at https://blog.ucsusa.org/jeremy-martin/something-stinks-california-must-end-manure-biomethane-accounting-gimmicks-in-its-low-carbon-fuel-standard/

California's transportation fuel policy is knee deep in cow poop, and it's not a good look. The California Air Resources Board (CARB) is considering amendments to its Low Carbon Fuel Standard (LCFS) regulation, but indicated they have no plans to address the problems caused by counter-productive subsidies for manure biomethane. CARB's use of the LCFS as a cash cow to fund manure digesters is bad transportation fuel policy and bad agricultural policy. Accounting gimmicks disguise a poorly run offset scheme as a magic carbon negative climate solution. CARB needs to phase out credits for "avoided methane pollution," refocus the LCFS on transportation and get to work developing a more suitable regulation for pollution from dairies.

The immediate goal of the current LCFS rulemaking is to stabilize LCFS credit markets so that the policy can continue to provide much needed support for transportation electrification. LCFS credit markets are out of whack because the supply of credits is outstripping the demand. CARB has proposed to rapidly increase the stringency of the standard to increase demand for credits, but it should also address the supply of credits, to make sure the fuels supported by the LCFS help move California towards a clean transportation future.

A quick glance at the latest data from CARB shows there are three large and growing sources of credits: bio-based diesel, biomethane and electricity.



Bio-based diesel, biomethane and electricity are the largest and fastest growing sources of LCFS credits in recent years. Each credit one metric ton of carbon dioxide equivalent pollution below the standard. Source California Air Resources Board.

I've written recently about why a Cap on Vegetable Oil-Based Fuels Will Stabilize and Strengthen California's Low Carbon Fuel Standard, which addresses the bio-based diesel credits. The growing credits for electricity reflect the growing number of EVs on the road in California, and support California's goal of phasing out combustion technologies in favor of zero emissions vehicles. But what about the rapidly increasing credits generated by biomethane? Vehicles powered by biomethane consume about one percent of California's transportation fuel, but in the first three quarters of 2023, biomethane used to fuel these vehicles accounted for 17 percent of LCFS credit generation. The reason a small amount of biomethane generates such a large amount of credit is that biomethane gets credit not only for reducing transportation emissions, but also for reducing methane pollution from manure lagoons at dairies and hog farms across the United States. CARB does not break down the share of credits awarded for avoided methane pollution, but according to my calculations 85 percent of credits awarded by the LCFS in 2023 have nothing to do with transportation but are a poorly disguised offset program creating a gold rush of unverified claims of avoided methane pollution from manure lagoons.

A recent post by UC Davis economist Aaron Smith puts the question quite directly, Cow Poop is Now a Big Part of California Fuel Policy: Are the state's new low-carbon fuel regulations full of BS? The short answer is yes, California's approach to subsidizing manure digesters through its transportation fuel policy is a disaster, and California officials need to wind down a poorly run offset program that is going to cost California drivers at the pump without creating a viable long term strategy to address the problem of manure methane pollution from huge dairies.

For the last few years, I have been getting deeper into manure policy than I ever expected. My primary expertise is in lifecycle-based transportation fuel policy, which has recently been providing increasing financial support for biomethane generated from anaerobic digesters at dairy manure lagoons. For a legal perspective on the topic, read the report (and summary blog) by Ruthie Lazenby at UCLA's Emmett

Institute, for an economic perspective see Aaron Smith at UC Davis, and to understand the impact of pollution from massive dairies on the people that live in adjacent communities, read this article on How a California Dairy Methane Project Threatens Residents' Air and Water.

In this blog, I will cover the following:

- Transportation fuel policies are based on lifecycle analysis.
- Negative carbon intensity scores are inconsistent with the LCFS and amount to an offset program.
- The LCFS manure methane offset program costs drivers more and delivers worse results than a similar policy designed to target dairy methane pollution.
- LCFS biomethane subsidies contribute to consolidation in the meat and dairy industry.
- California's LCFS is causing problems for other states and the federal government.

The LCFS is designed to hold fuel producers accountable for their supply chain emissions

The LCFS and related Clean Fuel Standard policies are performance standards for transportation fuel based on lifecycle analysis. This is a little different than other similar sounding policies like Renewable Energy Standards, which can create some confusion. A Renewable Energy Standard requires utilities to source an increasing amount of the energy they generate or sell from renewable sources like wind and solar, heading towards a 100 percent standard that would reflect a 100 percent renewable grid with no further combustion.

But while a Renewable Energy Standard treats all sources of qualifying renewable energy equally, the LCFS has a more complicated approach, based on lifecycle analysis. Under the LCFS each fuel pathway gets a unique carbon intensity (CI) based on a lifecycle analysis of the greenhouse gas emissions associated with the production and use of the fuel. This approach originated from the recognition that many alternative fuels, especially ethanol, involve a lot of fossil fuels and other pollution in their production. When I started working on biofuel policy back in 2008, there was a lot of criticism of corn ethanol because in some cases it had lifecycle emissions higher than gasoline. This conclusion came from adding up the emissions from coal used to power the production process, natural gas-based fertilizer and diesel fuel used to farm and transport the corn and ethanol. To address this concern some folks at UC Davis and Berkeley had the idea of giving transportation fuels partial credit based on how much they reduced emissions on a lifecycle basis compared to gasoline or diesel. This, in a nutshell, is the logic of the LCFS. For more information on this type of policy see our page on Clean Fuel Standards.

Gasoline has a CI of about 100 grams carbon dioxide equivalent pollution per megajoule of fuel energy (g/MJ) once the emissions from extracting oil, refining it into gasoline and burning it in cars and trucks are added up. The CI of an electric vehicle charged with solar power is zero, and most of the biofuels fall somewhere in the middle[9]. This approach holds fuel producers accountable for reducing fossil fuel use and other global warming pollution in their supply chains. When the LCFS eventually gets to a carbon intensity of zero, you would think all the fuels used to power transportation should be zero carbon fuels.

---

[9] For more on the carbon intensity of transportation fuels, see my 2016 report, Fueling a Clean Transportation Future. For more technical discussion on lifecycle methodology issues, see the report of a 2022 National Academies committee on which I served, Current Methods for Life-Cycle Analyses of Low-Carbon Transportation Fuels in the United States.

But unfortunately, this is where the implementation of the LCFS has drifted away from this idea of partial credit to hold fuel producers accountable for their own supply chains.

Negative CI scores are nothing more than a poorly regulated offset program

As Professor Smith explains in his latest cow poop post, California has been giving manure digesters large negative CI scores. "The carbon intensity of dairy [biomethane] ranges between -102.79 and -790.41 depending on characteristics of the digester. The current average carbon intensity for dairy [biomethane] is -269." A negative CI score would suggest an almost magical climate solution that pulls several carbon dioxide molecules from the atmosphere for each one that comes from the tailpipe of a truck running on dairy biomethane. Unfortunately, this is far from the truth. The justification for negative CI scores is an assumption built into the lifecycle analysis that if the methane was not used as transportation fuel it would be emitted into the atmosphere. And because methane is such a potent heat trapping gas, credit for avoided methane emissions can be quite large.

Without the credit for avoided methane pollution the CI of dairy methane would be about 36 g/MJ[10] instead of -269 g/MJ, which means that 85 percent of the credit claimed by dairy biomethane is associated with avoided methane pollution at the manure lagoon. Only 15 percent of the climate benefit assigned to dairy biomethane is associated with replacing fossil fuels with bio-derived fuel used for transportation[11].

Blurring together the impact on transportation and agriculture creates confusion and leads to exaggerated claims of the benefits of manure digesters. Considered as a source of energy, anaerobic digesters are an expensive way to produce a small amount of energy. As Professor Smith explained in an earlier post, "the cost of an anaerobic digester is 10 times the market value of the gas it produces." Dairy manure digesters are also an expensive strategy to mitigate methane emissions. More optimistic assessments of cost effectiveness ignore the multiple subsidies digesters receive, double (or triple) counting the climate benefits while understating the costs.

Professor Smith's most recent blog explains that the main motivation to keep the avoided methane offset scheme in the LCFS is to continue to supply incentives to California dairy farmers to cover the high costs of installing and operating digesters as a means of reducing methane pollution from dairies.

Negative CI scores undermine California's goal of phasing out fossil fuels and combustion fuels in general. Imagine a fleet of 7 diesel trucks in California, owned by a progressive company that wants to achieve carbon neutrality. Under existing LCFS accounting, this hypothetical company can convert 2 of its 7 trucks to run on compressed natural gas and contract with a manure digester to purchase the rights to match the fossil gas consumption of the trucks to the digester operator's pipeline gas injection somewhere else in the continental United States (this is called book and claim accounting). According to the logic of the LCFS, the two biomethane fueled trucks now have negative emissions that more than offset the emissions of the 5 diesel trucks, so the fleet is notionally carbon neutral.

---

[10] O'Malley, J., N. Pavlenko, Y.H. Kim. 2023. 2030 California Renewable Natural Gas Outlook: Resource Assessment, Market Opportunities, And Environmental Performance
[11] This calculation is based on average carbon intensity of a dairy digester of -269, as reported in Aaron Smith's January 2024 post, the 2024 LCFS standard for diesel of 87.89 g /MJ and a carbon intensity of 36.4 g/MJ for dairy biomethane without avoided methane credits, per O'Malley, J., N. Pavlenko, Y.H. Kim

The key word here is ***offset***. Obviously the 5 diesel trucks are still using fossil fuels and all 7 trucks are using internal combustion engines, creating tailpipe pollution that harms people in the communities in which the trucks operate. The claim embedded in the LCFS carbon intensity score is that avoided methane emissions from a manure lagoon offset the fossil CO2 emissions from the production and use of fossil diesel. Officially CARB claims that the LCFS includes no offset program. If it did, it would be subject to rules governing offsets that CARB would be required to enforce. I am not a lawyer, so I won't venture a legal opinion, but from where I sit this is a distinction without a difference. A negative CI score is an offset because it allows continued use of fossil fuels in a regime that claims to achieve zero emissions.

Negative CI scores are inconsistent with the logic of holding fuel producers accountable for the fossil fuel use and global warming pollution in their supply chains. It flips this logic on its head by allowing fossil fuel producers to continue to sell fossil fuels by claiming credit for offsetting methane emissions reductions that are part of a milk or meat producer's supply chain. And unfortunately, CARB's insistence that it is not running an offset scheme keeps them from running it properly. Thus, the LCFS does not require evidence that claimed methane emissions reductions are real and additional, as would be required from any credible offset program.

Transportation fuel regulations are not the right tool to reduce dairy methane pollution

As a general rule, public policies are more effective when they directly address the problem they are trying to solve. The LCFS regulates oil refiners, who are primarily responsible for the production of high carbon intensity transportation fuel. The use of carbon intensity as a metric for the LCFS adds complexity, but it allows for a comprehensive approach to an increasingly diverse set of transportation fuels, including gasoline and diesel, various biofuels and different sources of electricity. The LCFS does not stand alone, but complements regulations that require car and truck manufacturers, fleets, and electric utilities to reduce pollution from their products and services.

The primary business of dairies is to produce milk rather than transportation fuel, so using the LCFS to reduce pollution from dairies is quite indirect. To illustrate the problems caused by this indirect approach, consider how things would be different if the LCFS were adapted to directly target dairy pollution by creating a **Low Carbon Milk Standard** that operated alongside the LCFS. This hypothetical Low Carbon Milk Standard would resemble the LCFS but focus on milk rather than gasoline and diesel. It would assign a carbon intensity score to milk sold in California and set a steadily decreasing standard for the industry. I shared this idea with CARB staff and leadership last August, to help explain why focusing regulations on methane mitigation would be a better strategy to meet California's methane goals than subsidizing manure biomethane production through a poorly run offset program.

Benefits of a Low Carbon Milk Standard (or other agricultural methane regulations)

Just as the LCFS is based on the supply chain emissions of transportation fuel per unit of energy, a low carbon milk standard (LCMS) would be based on the supply chain emissions per unit of milk. While structurally similar, the milk supply chain emissions would include all the emissions associated with milk production, not just the manure, and would apply to all milk producers, whether they use a digester to capture and sell biomethane or use a different manure management strategy that minimizes the production of methane in the first place.

Under the LCFS, credits are only awarded for biomethane that is captured and used for fuel, and it is presumed that this methane is an inevitable consequence of milk production. Under a LCMS, there is no need for any such presumption, and all strategies that reduce methane pollution are treated equally. This avoids distorting the market for methane mitigation in favor of more polluting manure management strategies. California has an alternative manure management program (AMMP), that provides financial assistance for the implementation of non-digester manure management practices including composting and conversion to or expansion of pasture-based systems. These practices reduce climate pollution and provide other air and water quality benefits. Under the LCFS, dairies that use AMMP practices are at a competitive disadvantage compared to dairies that use digesters and can generate a substantial revenue stream from selling manure to operators of the digesters.

Opponents of dairy regulations claim that if California enacts stricter regulations on dairies than other states, dairies may just leave California, continuing to pollute but outside the reach of California regulations. This is called emissions leakage, and is discussed by both Ruthie Lazenby and Aaron Smith. The LCMS addresses leakage in the dairy sector the same way the LCFS does in the fuel sector. Out-of-state milk producers would be held to the same standards for pollution as California producers. The LCFS has survived legal challenges, and the same arguments should apply to an LCMS.

An LCMS would also address arguments that phasing out LCFS credits for avoided methane pollution would cause digesters to shut down, making it harder for California to meet its methane pollution targets. Digesters would continue to operate to meet the LCMS standard unless the dairies found a more cost-effective way to mitigate methane. Digesters make the most sense economically at large dairies, and at these facilities digesters would likely remain a cost-effective way to meet LCMS obligations. They can even keep selling biomethane to displace fossil gas, but the biomethane would not be credited with avoided methane emissions within transportation fuel or other energy policies.

Regulating manure methane directly would save California drivers money

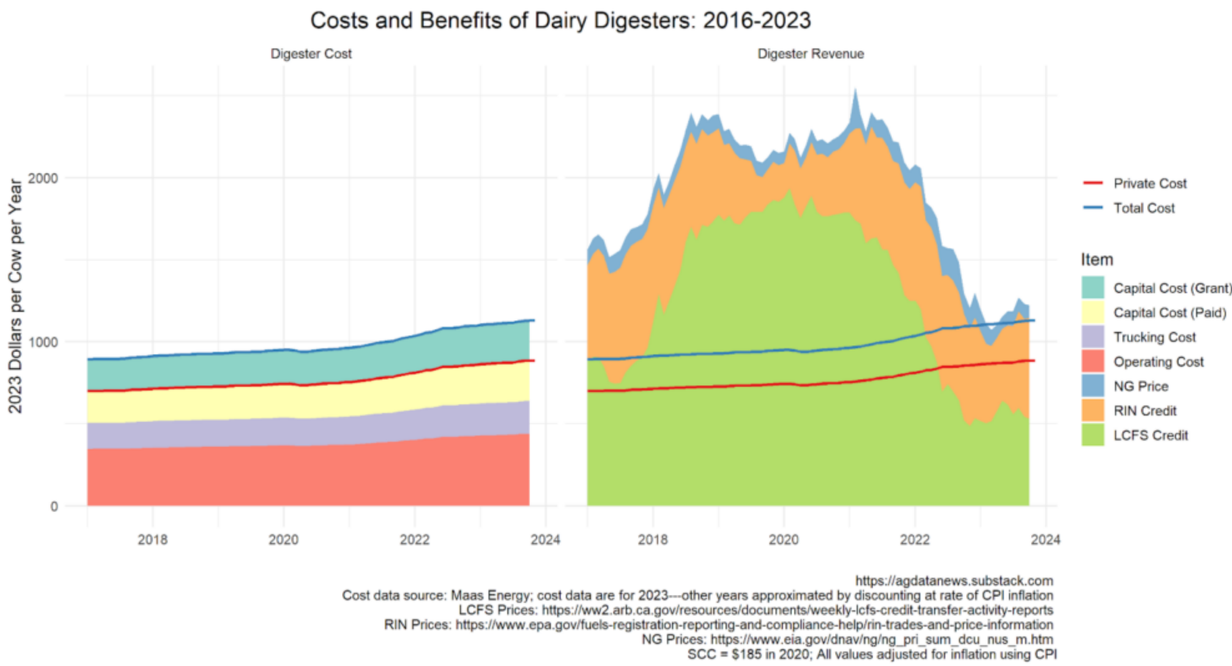
The California LCFS is designed to support the production of low carbon transportation fuel, and it applies the same lifecycle analysis methodology to all fuels, regardless of where they are produced, so long as they are used in California. As previously described, biomethane is allowed to use book and claim accounting. As a result, manure digesters at both dairies and swine concentrated animal feeding operations (CAFOs) all over the country have been granted LCFS pathways to produce biomethane with large negative CI scores. This means that California drivers are being asked to bear the cost of large subsidies for milk and meat producers nationwide, even though any reductions in methane pollution will not reduce California's emissions.

Regulating pollution from dairies through an LCMS or other regulation would shift the costs of reducing methane pollution to milk producers, and these costs will presumably be passed along to milk consumers. But these costs are likely to be quite a lot lower than current LCFS costs for three reasons. The LCFS is subsidizing manure digesters at dairy and swine CAFOs across the United States while the costs of a regulation would be limited to milk produced and/or sold in California, depending on the structure of the regulation. Second, a regulation developed for dairies should support a wider set of practices and technologies to mitigate pollution suitable for different types of dairies, which should bring down costs compared to limiting support to expensive digesters with gas cleanup and injection required to sell biomethane. And finally, a well-designed regulation should reduce the windfall profits that have accrued to biomethane developers selling credits into LCFS markets.

LCFS biomethane subsidies create a gold rush available only to very large farms, which encourages dairy (and meat) industry consolidation and distorts food markets

LCFS credits for avoided methane are one of several sources of support for digesters, with additional support coming from the Federal Renewable Fuels Standard Program (RFS) and grants from California's Department of Food and Agriculture and programs from the US Department of Agriculture. Professor Smith has analyzed how profitable these subsidies are in detail in his recent post.

> *Between mid 2018 and the end of 2021, revenues from selling biogas and the associated* [RFS credits, called RINs] *and LCFS credits were approximately double the cost of installing and running a typical digester, as shown in the figure below. LCFS credit prices have declined in the last two years, making the typical digester closer to a break even proposition. If and when credit prices go back up, then the profits will return.*



There has been an extensive coverage of the gold rush these generous subsidies started, in trade press and even the Wall Street Journal, which headlined its piece "California's Green-Energy Subsidies Spur a Gold Rush in Cow Manure: A lucrative state incentive to make natural gas from dairy waste is attracting companies from Amazon to Chevron."

These extremely profitable subsidies also contribute to consolidation. Building and operating a digester and the equipment required for gas cleanup and pipeline injection is very expensive, and even with large subsidies is generally only economic at very large dairy and swine CAFOs. At the largest CAFOs, the payments a farmer receives from a digester operator can be a significant portion of their income. But digesters generally don't make sense on smaller farms, because without thousands of cows or pigs, there is just not enough poop to make a digester and gas collection cost effective.

Smaller facilities can use other manure management strategies that reduce methane production in the first place or capture and flare methane, but since these strategies don't result in methane to sell to energy markets, they are excluded from LCFS biomethane subsidies. If digesters really were efficient producers of transportation fuel, LCFS support would make sense. But in reality, 85 percent of the LCFS subsidy is based on claims of avoided methane pollution, so excluding other strategies that can also avoid methane pollution distorts the lucrative market for avoided methane pollution by disguising it is a market for transportation fuel. This means that the largest dairies have preferential access to a lucrative revenue stream that is decoupled from the low margin high risk business of selling milk.

A 2020 report from the US Department of Agriculture on Consolidation in U.S. Dairy Farming highlights that "[t]he number of licensed U.S. dairy herds fell by more than half between 2002 and 2019, with an accelerating rate of decline in 2018 and 2019, even as milk production continued to grow." Several factors contribute to consolidation, and there is a heated argument over the evidence that LCFS subsidies have played a significant role. The basic economic arguments are clear enough. While key details are contested and not all the relevant data is publicly available, there is no real dispute that the LCFS biomethane subsidies have been a boon to large CAFO dairies and exclude smaller farms. This insight is not limited to opponents of the digesters and can also be found in the dairy trade press. A 2021 article explains the unintended consequences as follows:

> *The net effect will be that dairy farms with methane digesters and other green energy technologies will make decisions based more on returns from energy than returns from milk. It fundamentally changes dairy farm economics as well as milk and dairy product prices. If this comes to fruition, dairy market signals to raise or reduce milk production will be less effective. This could lead to a structural oversupply of milk in the domestic market[...]. Michael McCully. Hoard's Dairyman. 2021*

Structural oversupply in the milk market would certainly be hard for dairies without digesters whose business is limited to selling milk and are excluded from the LCFS biomethane gold rush.

The dispute is over the evidence that LCFS biomethane subsidies have already caused consolidation and how the role of the LCFS can be disentangled from other factors. The data question is complicated by the fact that key statistics are published only every 5 years. Until this week, the most recent data was from 2017, and comparing 2012 to 2017 does not say much about LCFS supported digester boom, which mostly happened after 2017. The data from the 2022 USDA Agriculture Census was released on February 13th and it confirms that dairy consolidation in California is continuing. The share of dairy cows in California on farms of 2500 cows or more grew from 46 percent in 2017 to 61 percent in 2022. Disentangling the role of the LCFS from other factors is beyond my expertise, so I am looking forward to reading what the experts have to say about it.

California's bad biomethane policy is causing problems across the United States

I work on transportation fuel policies across the United States. For several years I have been part of a Midwestern Clean Fuels Policy Initiative, and I have been working with Minnesota-based non-profits to develop a clean fuel policy for Minnesota. I was recently part of a Clean Transportation Standard Work Group run by the Minnesota Department of Transportation. The members of the work group have diverse perspectives on many things but agree that Minnesota should not copy California's LCFS but learn from it and create a policy that makes sense for Minnesota. Several Minnesota groups I have spoken with have major concerns that California LCFS subsidies for digesters are driving small dairies out of business. This is a very real concern in Minnesota, which ended in 2023 with 146 fewer dairy farms than it had at the beginning of the year. But a major challenge to crafting a Minnesota specific policy is that the largest dairies in Minnesota, run by a company called Riverview Farms, are already enrolled in the California LCFS. The result is that California drivers are spending increasing amounts of money to subsidize digesters in Minnesota in a manner that distorts dairy markets in Minnesota and is largely outside the control of Minnesota voters or policymakers.

The problem arises from treating manure digesters as a source of magic negative carbon energy instead of recognizing that their primary climate benefit is pollution mitigation from manure lagoons. Digesters do not pull methane out of the atmosphere; they capture methane that was created by the deliberate choice to collect and store manure in anaerobic conditions in huge lagoons. The idea that manure methane is uniquely valuable is leading to proposals from the biogas developers to truck manure from smaller farms to a central digester so that they too can participate in the digester gold rush, or to figure out how to install digesters at beef cattle feedlots that currently use dry manure management.

Crediting methane collected from these projects as if it is an inevitable consequence of manure management and assuming it would otherwise be vented into the atmosphere is clearly wrong from a technical perspective. It also sends a signal to farmers that they should get into the energy business and "get big or get out," in the infamous words of Nixon's Secretary of Agriculture Earl Butz. Most policymakers now recognize the harmful consequences of this attitude, so they should make sure their policies support their stated goals.

Decisions about the most suitable strategy for manure management are complex and depend on many local factors that affect not only the farm's profitability but also the local environment and community. These decisions should not be dominated by the results of a lifecycle analysis spreadsheet developed for a California transportation fuel regulation that only values "avoided methane pollution" when it is associated with transportation fuel production. If policymakers want to provide support to help farmers reduce methane pollution, they should provide at least equivalent support for methane pollution that is actually avoided because it was never created. When energy policy and agricultural policy intersect, we should make sure the results are supporting good outcomes in both spheres, and the California LCFS credits for avoided methane pollution are clearly failing that test.

What started as a clever way for California regulators to indirectly support expensive dairy digester projects in California is putting smaller farms across the United States at a disadvantage, especially those that use more sustainable manure management strategies, and potentially pushing them out of the business entirely. The problem is not limited to transportation fuel policy, it is also setting a damaging precedent that threatens to undermine the integrity of numerous new lifecycle-based tax credits, including the federal clean hydrogen production tax credit .

Agricultural methane policy should help food producers reduce pollution rather than paying for poop

Real harm results from disguising manure digesters as a magic negative carbon energy technology. Reducing pollution from food production is important, and so is scaling up renewable energy production to replace fossil fuels. Connecting these goals with a de facto offset regime is creating a lot of problems, and we need a better approach.

Policy makers must ensure that regulations and incentives shaping our food system not only address methane pollution from sources like manure lagoons but build a better food system—one that provides healthy, sustainably produced food for all and treats everyone at every stage of the system fairly. This is a big task, which can seem daunting and unrealistic. The magnitude of the challenge leads some to argue digester subsidies, by whatever means they can be financed, are a justifiable short-term expedient to address an urgent problem. But California's de facto offset regime is doing more harm than good, undermining California's transportation fuel policy, distorting milk and meat markets across the country in favor of the largest producers of manure and setting a damaging precedent that could undermine federal support for hydrogen or any other policy based on lifecycle analysis.

Negative carbon intensity scores have no place in transportation fuel policies. These policies should support the transition away from fossil fuels and hold all fuel producers accountable for pollution in their supply chains. The California Legislature gave regulators authority to start regulating dairy pollution in 2024, and they should start developing these regulations. My hypothetical Low Carbon Milk Standard illustrates the major structural problem with the LCFS biomethane offset program that is fixed by refocusing dairy methane policy on the primary polluter. But real policies that affect agriculture should be designed to meet the needs of farmers, farm communities and the environment, and not copied directly from the energy or transportation fuel sector.

Policymakers outside of California should understand that supporting methane pollution reduction using lifecycle analysis accounting gimmicks can seriously backfire and hurt small farms. Any policy that aims to reduce pollution from milk (or meat) production, whether as part of a regulation or an incentive, must be designed to reduce methane pollution, rather than to increase biomethane use. Fixing our broken food system requires a more thoughtful approach that grapples with the realities of the system, rather than just throwing money at the largest polluters.

Sacramento, CA 95814

Health Group Support for Strong LCFS Standards

Dear Chair Randolph:

On behalf of the undersigned health organizations, we are writing to provide comments in support of a more health-protective and effective Low Carbon Fuel Standard (LCFS) for California. As the California Air Resources Board (CARB) considers amendments, we urge you to better align the program with the critical transition to zero-emission transportation needed to meet health-protective clean air and climate standards.

Despite decades of progress, California remains home to significant air pollution burdens. The American Lung Association's "State of the Air" 2023 report noted that 98 percent of Californians live in a community impacted by unhealthy levels of ozone and/or particle pollution and that six of the ten most ozone-polluted cities in the nation are in California. The health harms of breathing unhealthy air are well known to CARB and represent the lived experience of too many in our state, especially due to transportation pollution. The Health Effects Institute's latest review of hundreds of peer-reviewed research papers found that exposures to traffic pollution are associated with all-cause mortality, deaths due to heart disease and lung cancer deaths as well as new cases of asthma among children and adults. The transition to zero-emission transportation is core to CARB's work and must be aligned throughout the LCFS policy.

We appreciate that CARB has postponed the hearing on the LCFS and will hold an informational workshop in the coming months. We believe that these are important steps toward building a stronger program that advances the transition away from combustion everywhere possible and toward the rapid and equitable distribution of the benefits of zero-emission technologies. Several opportunities for strengthening the LCFS program to protect public health have been noted in CARB's workshops, earlier proposals and the current staff report. As the board considers the updated staff proposal, we offer the following comments:

277.1
- We support the original staff proposal to place a cap on credits for crop-based fuels rather than the sustainability reporting requirements included in the current proposal.

277.2
- We support the staff proposal shifting the Clean Fuel Rewards program's focus to rebates for medium- and heavy-duty vehicles and the proposal to increase the equity-based focus of light-duty charging credits.

277.3
- We support the intention to eliminate avoided methane emission credits but urge the board to act much sooner than the proposed phaseout at 2040 to limit ongoing incentives for new projects that facilitate more methane production as a means to capture LCFS credits.

277.4 • We support the proposal to curb credits for out-of-state projects that do not actually send fuel to - or support displacement of fossil gas use in - California.

277.5 • We support the proposed expansion of eligibility for alternative jet fuels to include intra-state travel. We also encourage the board to further expand credit eligibility to aviation and shipping sector projects utilizing zero-emission technologies.

277.6 • We encourage the board to consider an earlier phaseout of credits for petroleum development projects than the proposed phaseout at 2040.

Overall, we urge the board to consider a stronger LCFS program that increases the role of zero-emission technologies and reduces crediting for projects based on accounting strategies that extend fossil fuel consumption and combustion technologies. We look forward to continuing to work with CARB staff and the Board on this issue. If you have any questions, please contact Will Barrett at William.Barrett@Lung.org.

California Air Resources Board
1001 I Street
Sacramento, CA 95815

RE: Proposed Low Carbon Fuel Standard Amendments

Dear California Air Resources Board Members and Staff,

Thank you for the opportunity to provide our comments and recommendations on the proposed Low Carbon Fuel Standard (LCFS) Amendments. We greatly appreciate the California Air Resources Board's (CARB) leadership in supporting and accelerating the transition to zero emission freight. California has led the way on cleaning up the transportation sector by designing and implementing a comprehensive suite of policies to address this multi-faceted challenge, including both sticks and carrots to increase vehicle supply, boost demand, and facilitate infrastructure deployment and grid integration. LCFS is a critical piece of this overall puzzle in terms of incentivizing infrastructure buildout and improving the total cost of ownership for electric vehicles, particularly for the medium- and heavy-duty vehicle sector.

The undersigned Joint MHD EV Infrastructure Parties develop single and multi-fleet EV charging hubs that provide third-party owned charging-as-a-service to medium and heavy duty (MHD) EV fleet owners. Multi-fleet EV charging hubs are especially important for enabling small (and many large) businesses without adequate onsite charging capability to electrify their fleet vehicles to reduce costs, improve employee and community health and achieve California policy goals for clean vehicle deployment and decarbonization. Multi-fleet EV charging hubs provide the added benefit of increasing charging infrastructure utilization, enabling more vehicles to charge per charger without triggering costly system upgrades, thereby reducing the overall cost for all utility ratepayers. Our collective business models foster the concentration of electrical loads in strategically chosen locations, facilitating a more seamless transition to MHD EVs for commercial fleets.

With critical adjustments, LCFS has the potential to be the single most important tool in helping the state meet its zero emission transportation goals and recent regulations – the Advanced Clean Trucks (ACT) and Advanced Clean Fleets (ACF) regulations in particular. We appreciate CARB staff's collaboration to date on the provisions most relevant to our businesses, particularly with regard to the MHD Fast Charging Infrastructure (MHD-FCI) provision. We strongly support the creation of the MHD-FCI program, though additional modifications are needed to maximize the clean air and climate benefits it can unlock. We also applaud staff for recognizing the need for program stringency updates to support credit prices as a robust market is needed for LCFS to truly catalyze private investment.

To fully realize the potential benefits of LCFS for truck electrification, we respectfully make the following recommendations.

1. **Maximize the benefits of the proposed medium- and heavy-duty fast charging infrastructure (MHD-FCI) program by increasing flexibility to better support the deployment of necessary charging infrastructure** in advance of truck deployment at the speed and scale to meet California's policy goals and regulations (e.g. CARB's recent Advanced Clean Fleets)
    A. **Eliminate geographic limitations** on MHD-FCI eligibility to improve program effectiveness, better align with fleet needs, mitigate delays, and reduce overall costs.
    B. **Eliminate the 10 FSE per-site cap** to enable the scale necessary to meet state goals and to encourage cost reductions that come with upfront investments and larger projects.

C. **Eliminate or reduce the 250kW minimum capacity** to enable infrastructure providers to provide the variety of solutions the market needs.
D. **Clarify rules around access requirements** for shared depots to avoid creating confusion around eligibility requirements.
E. **Increase overall MHD-FCI program size** to enable infrastructure deployment at the scale and pace required to meet California state goals.

2. **Strengthen and update the overall LCFS program to better align with long-term state goals and ambitions** by implementing changes that support credit prices.

We understand the board vote has been postponed to allow more time for consideration of potential program modifications, including some of what we outline above. We acknowledge the need for additional discussion, but also urge the board to move quickly with a decision in Q2 of this year. Market participants, including infrastructure providers, need certainty around program details and a lengthy delay will chill investment. Additional details and rationale for our highest priority recommendations can be found below.

1. **Maximize the benefits of the proposed medium- and heavy-duty fast charging infrastructure (MHD-FCI) program by increasing flexibility to better support the deployment of necessary charging infrastructure.**

At this early stage of the market, with under 1,000 medium- and heavy-duty electric trucks and vans on California roads based on recent data[1], the uncertainty around truck charger utilization in the near term creates a risk that many would-be infrastructure investors are unwilling to take. The result is a lack of sufficient investment in large scale charging for electric trucks, and this in turn is slowing the deployment of the electric trucks. The Fast-Charging Infrastructure (FCI) program has already proven to be an elegant and effective way to overcome this fundamental challenge, and we deeply appreciate CARB's proposal to add an FCI for the MHD sector (MHD-FCI) and the efforts to date to include multi-fleet charging hubs in program design.

With critical adjustments, MHD-FCI could be the single most powerful tool for attracting private capital to this sector, accelerating the rollout of charging infrastructure ahead of vehicle deployment. MHD-FCI has the potential to provide some certainty around revenue, thereby de-risking these projects and attracting private investment. The key is to design a program that is sufficiently robust and flexible to match California's clean air and climate ambitions. This is a unique opportunity to catalyze deployment of truck charging infrastructure just when it is needed most to support the state's clean truck regulations and programs. The draft proposal has laid the foundation for a strong program. With a few key modifications, MHD-FCI can deliver widespread health, air quality, and climate benefits while attracting private investment to a sector that will need it to scale up to meet the State's goals.

A. ***Eliminate geographic limitations on MHD-FCI eligibility to improve program effectiveness, better align with fleet needs, mitigate delays, and reduce overall costs, for both Private and Shared MHD-FCI charging site types.***

Section § 95486.3 outlines MHD-FCI eligibility requirements, including the following: *"Located within one mile of a reading or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent*

[1] California Energy Commission Medium- and Heavy-Duty Zero-Emission Vehicles in California. As of the end of 2022, the total medium- and heavy-duty ZEV population in California included 272 trucks and 340 vans.

to a property used for medium or heavy-duty vehicle overnight parking, or has received capital funding from a State or Federal competitive grant program that includes location evaluation as criteria." We recommend removing these geographic restrictions entirely as they will undercut program effectiveness, delay deployment, and increase costs for charging and grid upgrades for MHD-FCI Shared charging sites, and are also irrelevant to the MHD-FCI Private charging sites category; public navigability and accessibility are not merits of an MHD-FCI Private charging site that is by definition precisely on route for the associated Private fleet.

Corridor charging does not address operational needs for many high-priority market segments. While corridor-based charging may be part of the solution for long-haul trucking, it does not align well with the duty cycles and day-to-day operations of short haul and return-to-base fleets such as drayage, middle mile, and last mile delivery. These are the vehicles that are expected to electrify first due to ACF regulations and the overall "fit" of battery electric vehicle technology today. These vehicles would benefit from charging in areas where they operate and where they are domiciled, and these locations do not necessarily fall within one mile of a corridor. Additional flexibility is needed to meet needs for the broader MHD sector, beyond just long-haul applications, and to serve the market segments most ripe for rapid decarbonization.

Focusing the program on corridors also inadequately considers grid constraints and the implications that this may have on fleet electrification. Depots will generally have large power demands (often 5-15MW). Land with access to sufficient grid capacity on distribution feeders is very limited, and the number of suitable sites shrinks even further when factoring in zoning, permitting, and ingress/egress requirements. The proposed one-mile restriction would not only further limit where MHD charging can occur but also funnel depots to areas that would necessitate costly and lengthy grid upgrades – with the unfortunate consequence of slowing down charging infrastructure deployment and potentially increasing electric rates for all Californians. Additional flexibility is needed to account for the constraints on our grid and to facilitate timely, cost-effective infrastructure buildout.

The proposed program does include language allowing eligibility for sites adjacent to overnight parking and sites that have received certain state or federal funds. While we appreciate these provisions and they are directionally helpful, this language is still far too limiting. The language around existing parking does not account for grid constraints or for the fact that fleet operations are evolving and parking locations will not be static, particularly given the challenges associated with infrastructure deployment (e.g., grid constraints, landlord restrictions, etc.). Indeed, greenfield sites with overnight parking should not be excluded just because they are not currently providing truck parking. With regard to allowing MHD-FCI for sites that have won competitive grant solicitations, we appreciate the intention but note that (a) funding is limited and budgets are under pressure, so this is a relatively small number of sites, and (b) local funding appears to be excluded despite the fact that many local air districts have programs aimed at MHD-fleet electrification.

278.1 **We recommend completely eliminating geographic restrictions in order to maximize the benefits of the program**. Business models, amount of investment needed to build charging sites, and investor pressures will minimize the risk of stranded assets and ensure that charger deployments align with fleet operational needs for both Shared and Private charging sites in a network. If CARB ultimately decides that limits are needed, we recommend specific changes to provide added flexibility, open up additional sites, and avoid unintentional delays and potential cost increases.

- **Recommendation: Strike section §95486.3 (b)(1)(B)2** to provide implementation flexibility. This is the best course of action to accelerate progress on electrification and to avoid unintended consequences.
- **Suboptimal alternative:** We maintain that a program without geographic limits would best serve CARB goals and that limits are unnecessary given the natural market forces that will push for optimized locations. If, however, CARB determines that some geographic limits are necessary for shared charging sites, we suggest increasing flexibility with the following changes to existing language to address corridor distance, the realities of parking and fleet operations, and the importance of local decision-making in this sector:
  2. *located within ~~one mile~~ five miles of a ready~~ing~~ or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent to a property that allows ~~used for~~ medium or heavy-duty vehicle overnight parking at the time credits are claimed, or has received capital funding from a local, State or Federal competitive grant program. ~~that includes location evaluation as criteria~~*

B. Eliminate the 10 FSE per-site cap to enable the scale necessary to meet state goals and to encourage cost reductions that come with upfront investments and scale.

Section §95486.3 states *"The total number for all FSEs claiming MHDFCI credit owned by a single applicant within ¼ mile of an MHD-FCI site cannot exceed ten."* Limiting eligibility to 10 FSEs per site would severely restrict program effectiveness, and would hamstring the ability for charging infrastructure to be deployed at the speed and scale required by the Advanced Clean Fleets and Advanced Clean Trucks regulations.

Our companies are developing depots of various sizes, including within the 100-truck range, as depots of this size have the scale to bring down costs for customers. The purpose of the FCI program is to encourage the deployment of charging infrastructure in advance of truck availability by providing bridge revenue as truck deployments ramp up. Limiting participation to a small proportion of a site's chargers – in many instances a 90% reduction -- would make the program ineffective for these depots. With this restriction, the program would perversely only support the sites with higher per-port costs – which is not in California's best interests.

According to CEC analysis, we estimate that California must install an average of approximately 66 MHD chargers a day through 2035[2]. This is an astronomical rate of growth, and the FCI is an elegant tool to help achieve that. Limiting the eligible number of chargers in a depot would be catastrophic to our efforts to meet the scale and scope of infrastructure deployment required by CARB regulation.

---

[2] This calculation is based on the CEC AB 2127 report: Assembly Bill 2127 Second Electric Vehicle Charging Infrastructure Assessment: Assessing Charging Needs to Support Zero-Emission Vehicles in 2030 and 2035 | California Energy Commission. To support medium- and heavy-duty plug-in electric vehicles, California will need about 109,000 depot chargers and 5,500 public chargers for 155,000 vehicles in 2030, and 256,000 depot chargers and 8,500 public chargers for 377,000 vehicles in 2035.

Given other provisions in the draft language, we believe it has been suggested that the intention behind the 10 FSE per site limit may be to force 1 MW chargers. If so, there are multiple reasons to reconsider. First, not all customers and use cases require megawatt charging, and there are cost tradeoffs with higher power charging. Secondly, there are also grid benefits to lower power charging -- maximizing the utilization of the existing distribution network thereby minimizes potential rate impacts. Thirdly, 1 MW chargers do not yet exist at broad commercial scale. Finally, there are no trucks currently commercially available that can take 1 MW; though some MW+ models are being developed, they are not expected to be commercially available at scale for some time.

Finally, as noted above, the proposed amendments also include a limit on individual entities claiming credits beyond 10 MW of nameplate charger capacity within ¼ of that entity's site. This overall site claiming capacity limit is sufficient to ensure a diversity of sites and applicants; there is no need for a separate FSE cap.

278.2

- **Recommendation: Eliminate the 10 FSE per site limit by striking section §95486.3(b)(2)(D)** to enable the scale necessary to meet state goals and to encourage cost reductions that come with upfront investments and larger projects. The 10 MW overall site claiming capacity limit is sufficient to meet policy objectives.

C. Eliminate or reduce the 250kW minimum capacity to enable infrastructure providers to provide the variety of solutions the market needs.

Section §95486.3 creates a minimum per-FSE power rating threshold: *"Each FSE at an MHD-FCI site must have a minimum nameplate power rating of 250 kW."* This is unnecessary and should be either removed or reduced.

The state has a policy interest in having vehicles charged as "low and slow" as possible. Lower power charging will maximize utilization of the existing distribution network, putting downward pressure on rates. For light duty vehicles, for example, home charging is encouraged at L1 and L2 levels. In the MHD sector, many trucks are not able to charge 'at home', as where they are domiciled may not have sufficient hosting capacity to serve the massive amounts of power that a fleet of trucks with very large batteries need, and small operators often do not own property or have long term leases sufficient to amortize the high costs of installing chargers. In these instances, 3rd party depots play the role of both 'home charging' (i.e. overnight dwell) and pulling into a DCFC on a highway for a mid-route refill.

There is a tradeoff between the speed of charging and the cost to serve the massive numbers of vehicles that must be electrified, and artificially biasing the market toward higher power charging through size minimums for all use cases will both increase costs and grid impacts. This is why many 3rd party depots are designed with a mix of fast opportunity chargers and slower (and cheaper) overnight or long dwell chargers - to have a mix of technologies aligned to varying use cases, designed to keep costs as low as possible while meeting a range of needs. We believe that the market can and should decide on the appropriate power levels for depot charging. Further, this is a matter of equity, as the entities that will be most impacted by the higher costs are the less-well-capitalized fleets and drivers that cannot charge 'at home' and must rely on 3rd party depots.

- **Recommendation: Eliminate the 250kW minimum by striking section §95486.3(b)(1)(E)** to allow
278.3 greater flexibility on site design and cost control. If CARB sees a need for a minimum to focus on fast
charging, establish 150kW as the minimum nameplate power rating.

D. *Clarify rules around access requirements for shared depots to avoid creating confusion around eligibility requirements.*

Appendix A-1 defines "shared MHD-FCI charging site" as *"…an EV fast charging site that is available to at least two MHD EV fleets under different ownership, or to the public for at least 12 hours each day…" and states that " The site must not have obstructions or obstacles precluding the fleet vehicles from entering site premises, and no registered equipment training shall be required for individuals to use the site."* It is our understanding that CARB intends to allow shared depot charging, which we strongly support. These sites generally will have security measures (e.g., security fencing and access control) to ensure safety of vehicles and cargo and to ensure access to customers from multiple authorized fleets. These sorts of standard security measures should not be considered obstacles. We recommend clarifying language to align with market needs and eliminate any future questions around eligibility.

- **Recommendation:** Clarify the definition of shared MHD-FCI charging site to remove uncertainty
around security measures at shared depot sites. Suggested language: *"'Shared MHD-FCI charging
278.4 site' means an EV fast charging site that is available to at least two MHD EV fleets under different
ownership, or to the public for at least 12 hours each day. ~~The site must not have obstructions or~~
Access controls and security measures are allowed so long as there are no obstacles precluding the
authorized fleet vehicles from entering site premises, and no registered equipment training shall be
required for individuals to use the site."*

E. *Increase overall MHD-FCI program size to enable infrastructure deployment at the scale and pace required to meet California state goals.*

The MHD-FCI program is limited to 2.5% of the previous quarter deficits. At 2025 deficit levels, we estimate this would support as little as 635 MW of MHD charging capacity, increasing as utilization ramps up over time.[3] According to the CEC's AB 2127 analysis, the state will need about 2,900 MW of MHD charging by 2025 and 11.6 GW of MHD charging by 2030.[4] Additional support is needed to attract the scale of private capital required,

---

[3] This calculation was derived leveraging the formulas from Appendix A-2 Proposed Regulation Order, section § 95486.3.(b)(2)(G) and section § 95486.3.(b)(5)(G) with the following assumptions: previous quarter deficits = 8,082,115 MT (based on CARB CATS model 2025 forecast); shared MHD-FCI charging site model selection; 85% uptime; and 5% utilization. Supported capacity will vary with utilization, uptime, and other assumptions.

[4] The California Energy Commission's AB 2127 report uses the HEVI-load model to forecast the number of depot and public chargers required for MHD charging under the AATE3 primary scenario. This forecast predicts the number of chargers and their respective power ratings that will be required in 2025 and 2030, as seen in Appendix-H, Table H-1. The sum of the total MHD charging capacity based on this forecast was calculated to be 2,900 MW and 11,600 MW by 2025 and 2030, respectively, by taking the sum-product of the number of chargers and their respective power rating.

particularly at this nascent stage of the market with uncertainty around commercial-scale truck deployment timelines and with both fleets and OEMs citing infrastructure as a primary limiting factor.

278.5
- **Recommendation: Increase the program cap from 2.5% to 5%.** We are at a critical launch point for both ACT and ACF and believe a higher cap – we recommend at least 5% - is warranted to begin deploying a network that will enable the market to take off. As momentum builds and the on-road electric truck population grows, CARB might consider reducing the cap.

2. Strengthen and update the overall LCFS program to better align with long-term state goals and ambitions.

LCFS has played a critical role in reducing transportation-related emissions in California since its inception. However, the market has become imbalanced in recent years, credit prices have fallen precipitously, and the program is beginning to diverge from California's longer term market transformation goals for the transportation sector.

From our standpoint as a group of companies interested in rapid and widespread electrification, the primary overarching issue with the LCFS market is that historically low credit prices are undermining investor confidence in the market. When CARB prepared its TCO analysis for ACF, it modeled credit values of $200 through 2030[5] – but credit values have plummeted to around $60[6] and the market has not reacted positively to the most recent proposed language. CARB is proposing multiple regulatory changes to begin addressing the challenges undercutting this market, including a proposal to step down program stringency in 2025 as well as the creation of Automatic Acceleration Mechanism. We generally support these provisions and appreciate the recognition that both are necessary given recent market dynamics. However, despite these proposals, we have not yet identified any analysts or brokers who see a near-term rebound in credit prices absent additional changes to the proposed regulation.

278.6
- **Recommendation: Additional program modifications are needed to support credit prices and drive innovation and investment that supports California state goals.** CARB has multiple options to support credit prices:
    - Some fuel sector experts and advocates have called for **further increases in stringency and earlier implementation of the Automatic Acceleration Mechanism** as one way to address the oversupply issues undercutting the market.
    - Many environmental advocates and community-based organizations are calling for **caps on certain crop-based biofuels** and as an important part of the solution.[7]

We recognize that this is a complicated topic with many details falling outside of our core area of expertise. Others are better positioned to weigh in on expected renewable fuel volumes, land use change, and localized

[6] Weekly LCFS Credit Transfer Activity Reports | California Air Resources Board. The average for February 5th-11th was $60.52.

[7] For example, see "Assembly Bill 32 Environmental Justice Advisory Committee (EJAC) DRAFT Recommendations to the California Air Resources Board (CARB) on the Low Carbon Fuel Standard Regulation Updates" (available online at 1-lcfs2024-VjMFaQNjUGABWFA0.pdf (ca.gov)) as well as comments submitted by the World Resources Institute (WRI) and others.

health impacts. It is clear that additional program changes are needed to address the supply/demand imbalance that is undercutting credit prices and we believe there is value in better aligning this policy with California's goal of a zero-emission transportation sector.

California continues to play a leadership role in reducing emissions, improving air quality, and supporting private sector innovation through strong market signals. The state has set very ambitious targets and timelines for electrifying medium- and heavy-duty vehicles, calling for a complete market transformation that will require massive investment, cross-sector collaboration, and forward-looking policy intervention. Companies like ours are stepping in to help achieve our shared goals, but infrastructure investment on the scale we need to see has not yet materialized. **With the modifications outlined above, LCFS can be the single most powerful tool California has to attract the private capital needed to build out truck charging infrastructure.** LCFS is one of the few remaining tools California has to drive investment in charging infrastructure with looming budget deficits and a crisis of rising electricity rates. We must not miss this opportunity to better align LCFS with California's goals.

We thank you for your efforts and are happy to follow up with you or CARB staff at any time.

Yours,

Re: NRDC Recommendations for the Low-Carbon Fuel Standard Program

The LCFS Program is one of California's largest sources of funding for clean transportation. But, as NRDC and other commenters have extensively described, some aspects of the program's current design have unintended consequences that prove non-beneficial or worse for communities and the climate. In particular, the program channels billions of dollars to both biomethane, which CARB's own Scoping Plan finds is not a significant, long-term decarbonization solution for the transportation sector,[1] and to lipid-based biofuels, which have dubious carbon benefits and significant harmful impacts that are not effectively addressed by CARB's Staff Proposal.[2] The LCFS Program's reliance on these fuels exacerbates harm to communities that live near highways, refineries, and large livestock operations,[3] and it detracts from CARB's electric vehicle (EV) targets. The Staff Proposal represents a missed opportunity to fix the LCFS to make it into the truly effective and progressive climate measure it was intended to be.

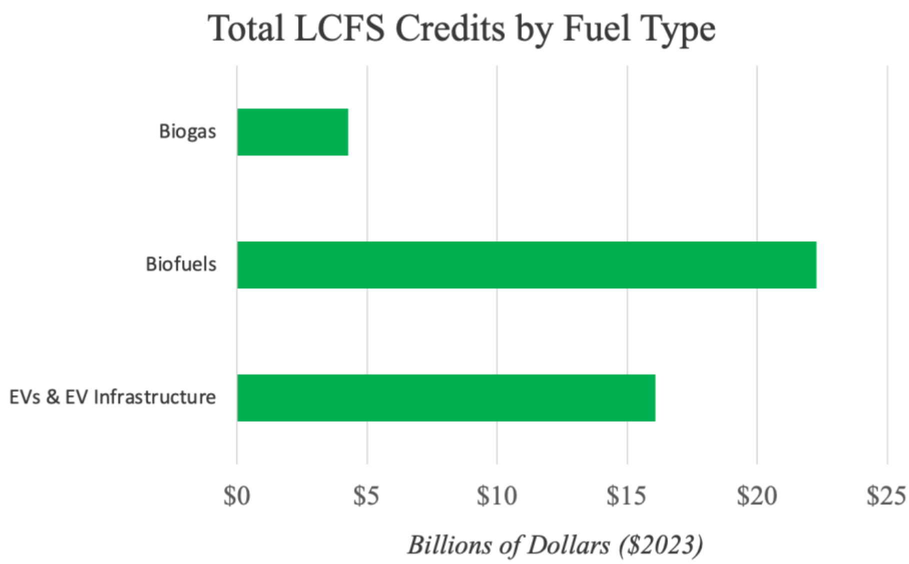

Figure 1: *LCFS funding by fuel type (2011-2022), based on data from UC Davis LCFS data visualization tool.[4] Source: NRDC*

Hundreds of public commenters and numerous environmental justice and environmental organizations have called on CARB to address these issues and to bring the LCFS Program into alignment with California's climate and environmental justice objectives.[5] Yet the Staff Proposal does not effectively address these concerns. Californians pay for the LCFS Program at the pump, and they deserve to see their hard-earned money supporting clean, non-polluting technologies that advance climate action, improve air quality, benefit communities, and provide a pathway to the state's clean transportation future. We urge CARB to reform the LCFS Program, starting by hosting at least two additional Board meetings to consider significant changes to the Staff Proposal.

Below is a summary of the changes NRDC recommends to the Staff Proposal.

CARB Staff Proposal	NRDC Recommendations	
Extend avoided methane crediting for biomethane through 2040 for CNG vehicles and through 2045 for hydrogen production for any project that breaks ground before 2030.	**Correct the over-crediting of livestock biomethane this year** and utilize CARB's SB 1383 authority to open a proceeding by 2025 to regulate, track and report emissions from the agricultural sector.	279.1
Allow unrestricted crediting for lipid-based bioenergy produced from oil feedstocks in the food crop system, requiring only sustainability certification of the particular feedstock being refined.	**Establish a cap on lipid-biofuel feedstocks** to limit the use of food crop oils, and re-evaluate the carbon intensity of such fuels in a manner that considers feedstock fungibility and displacement.	279.2
Allow CO_2-enhanced oil recovery projects to continue to receive LCFS credits.	Disallow credit-generation for carbon capture projects that **utilize CO_2 for enhanced oil recovery**, in line with SB 1314.	279.3
Allow fossil hydrogen paired with biomethane environmental attributes to receive greater LCFS credits than green, electrolytic hydrogen.	**Ensure that credited hydrogen is truly climate-friendly** by requiring it to be produced with zero-carbon electricity that is incremental, deliverable, and hourly-matched.	279.4
Change the design of traditional LCFS credits for EVs by allowing base residential credits for charging stations in multi-family residences and establishing a new statewide rebate for MHD EVs, among other changes to base residential credits;	**Keep the design of base residential credits and the current program rules** (e.g., limits on credits, size of charging plazas) and extend the program to 2035;	279.5
Extend the current capacity credits for public DC fast chargers for light-duty EVs to 2030 but reduce the size of the program and limits it to rural and DAC areas;	**Allow emerging types of transportation electrification to earn credits** without a Tier 2 application;	279.6
	Grant larger credits to fixed guideways, transit buses and school buses;	279.7
Add a new capacity credit program for MHD EVs at public, shared depot and fleet locations to 2030 with many restrictions.	**Encourage more DCFC development,** including at shared depot and fleet locations for drayage, short-haul and delivery trucks.	279.8

Table 1: Comparison of the Staff Proposal with NRDC's recommended changes

279.1

1. **Avoided methane crediting for livestock biomethane is distorting the LCFS Program and the economics of the livestock industry, with detrimental consequences for communities and the climate.**

Staff proposes to extend avoided methane crediting for biomethane through 2040 for CNG vehicles and through 2045 for hydrogen production, with these extensions applying for any project that breaks ground before 2030. If approved, this recommendation would lock in the distortionary impacts of avoided methane crediting for decades – undermining California's clean transportation goals and harming communities that live near concentrated-animal feeding operations (CAFOs) and refineries. Instead, CARB must correct the over-crediting of livestock biomethane by the end of 2024 and utilize its SB 1383 authority to open a new proceeding specifically designed to regulate emissions from the agricultural sector.[6]

Today, the LCFS Program provides an outsized "avoided methane credit" to livestock biomethane based on the assumption that manure methane from CAFOs would be released into the atmosphere if not captured in digesters funded by the LCFS Program. This results in livestock biomethane (and fossil hydrogen produced with biomethane credits) receiving outsized carbon intensity (CI) scores that range from negative 300 to negative 400 tons CO_2e/Megajoule.[7] In comparison, the CI scores of renewable electricity and green, electrolytic hydrogen hover near zero. Since the program's inception, biomethane has received more than $1.26 billion ($2023) in LCFS credits due to avoided methane crediting.[8] This has spawned a digester industry that is reliant on these public resources and provides struggling industrial dairies with a new revenue stream.

[8] See Figure 1 above.

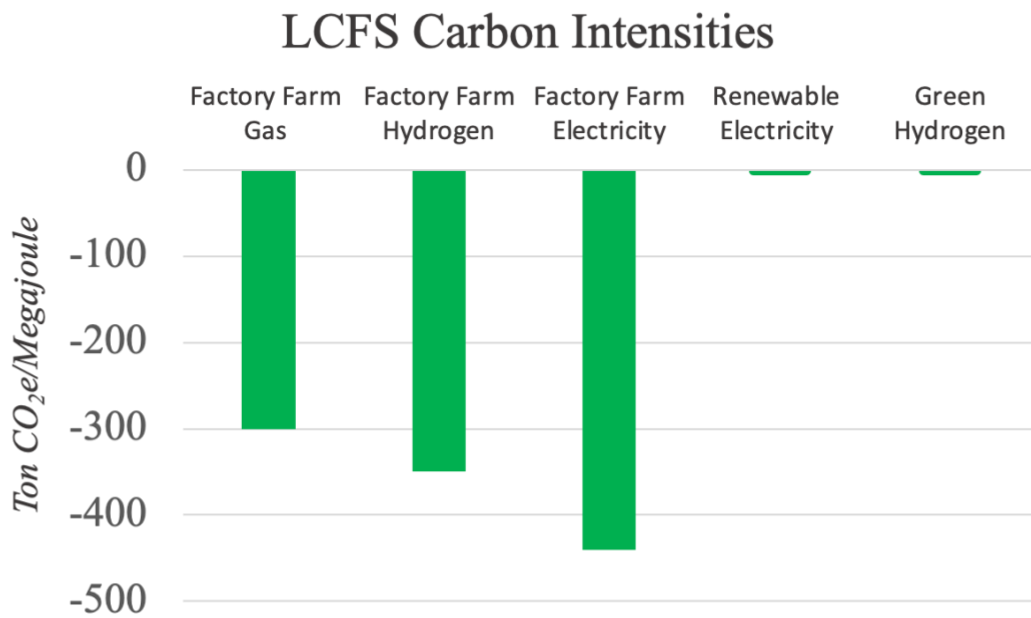

Figure 2: *Approximate carbon intensities under current LCFS CI scoring system, based on Stanford University Climate & Energy Policy Program modeling.*[9] *Source: NRDC*

Avoided methane crediting is distorting the LCFS Program. As shown above, the lowest possible CI score for renewable electricity is zero – placing it on an uneven playing field with biomethane and stifling the deployment of EVs and EV charging infrastructure. This results in one compressed natural gas (CNG) truck and three diesel trucks receiving the same amount of LCFS credits as four electric trucks[10] – despite CARB's objective of 100 percent zero-emission heavy-duty truck sales by 2036.[11] Similarly, under this scoring system, green electrolytic hydrogen with a minimum possible CI of zero receives far fewer credits than fossil hydrogen produced in a refinery that purchases biomethane's environmental attributes. Avoided methane crediting artificially sweetens the deal for biomethane in the LCFS, even as CARB

acknowledges via other policies that biomethane has a negligible role to play in decarbonizing transportation.[12]

The LCFS program's current design is harming communities living near CAFOs and refineries. CARB staff's proposal will continue to do the same. Outsized incentives for biomethane particularly benefit large livestock operations, which pollute the air and water of the communities who live near them.[13] Troublingly, recent research finds that dairy biomethane incentives from the LCFS are so large that they may enable increases in herd sizes even as dairy demand decreases.[14] In other words, the LCFS may actually be incentivizing the growth of CAFOs whose main product is not milk, but rather methane that industrial farms can capture and sell as a transportation fuel under the current LCFS framework.

Proponents of the avoided methane credit for biomethane argue that the LCFS is helping clean up emissions from the agricultural sector. But as a transportation fuels program, the LCFS should drive California towards a zero-emissions transportation future – not direct resources to expensive methane digesters that have little to no role in the clean transportation future. Because the LCFS is designed to be a transportation program, it is also not effective at addressing all of the climate, air, and water emissions from CAFOs. To fix the LCFS Program and meaningfully address agricultural emissions, CARB should remove avoided methane crediting in 2024 and open a new proceeding under CARB's SB 1383 authority to consider separate, dedicated policies to comprehensively address methane emissions from CAFOs.[15]

2. **Hydrogen credited as zero-emission or lower under the LCFS Program should be green, electrolytic hydrogen produced according to the "three pillars" of incrementality, deliverability, and hourly matching.**

The Staff Proposal continues to encourage hydrogen production through the LCFS Program with little attention to the true carbon intensity of production pathways. As demonstrated in Figure 2 above, under the LCFS Program, a refinery can produce polluting hydrogen from fossil gas (which emits harmful local air pollution as well as greenhouse gases), purchase LCFS credits for factory farm gas from anywhere in North America, and then sell their hydrogen on the market with a negative CI. Meanwhile, green hydrogen produced from solar electricity achieves a minimum CI of zero.

NRDC continues to call on CARB to ensure that, where hydrogen is credited as zero-emission or lower in the LCFS Program, it is green, electrolytic hydrogen produced with clean electricity that meets the three pillars of incrementality, deliverability, and hourly matching.[16] This will ensure that hydrogen credited as zero-emission is truly delivering emissions reductions.

- **Incrementality:** Also referred to as additionality, this requires that an electrolyzer be powered by *new* clean energy, thereby ensuring that the electrolyzer does not lead to an increase in fossil fuel combustion on the grid from resource shuffling.
- **Deliverability:** For an electrolyzer to claim that a clean energy project is offsetting its grid electricity consumption by displacing fossil fuels, the clean energy project needs to be delivering power into the same grid where the electrolyzer is located.
- **Temporal matching:** An electrolyzer drawing grid power should only be allowed to claim that its consumption is offset by clean energy during times when this clean energy is actually generating. Therefore, there needs to be a strong correlation, or "temporal matching," between times of electrolyzer operations and times of clean energy generation. Matching should be demonstrated on an hourly basis from 2028.

3. CARB's Staff's Proposed Measures to Address Biofuel Feedstock Sourcing Fail to Address the Problem of Fungibility

NRDC and numerous other commenters made a strong recommendation to CARB last year to impose caps on lipid bioenergy feedstocks. The specific reason given in support of that recommendation was that these feedstocks – in particular, virgin oils in the food crop market – are fungible. As explained in NRDC's 2023 Comment,[17] when large volumes of a feedstock such as soybean oil are diverted to energy production, the shortage created by that diversion will incentivize both additional land being devoted to grow more of the feedstock oil to address the shortage, and increased production of other types of oil that are fungible with the feedstock oil. The most problematic of these fungible oils, as explained, is palm oil, which is associated with large-scale deforestation and the ecological and carbon impacts that ensue. The 2023 Comment cited the extensive research supporting this concern by ICCT and others.

The solutions that CARB offers to this problem of food crop oil fungibility and displacement are incapable of addressing the issue. CARB proposes, first, that the specific feedstocks used in bioenergy refining must be traced to their point of origin and certified as not having caused recent deforestation; and second, that palm-derived fuels be removed from eligibility for credit generation. These proposals fail to address the fundamental challenges of fungibility and displacement.

Regarding the certification requirement, the fact that a particular quantum of oil used in biodiesel production is supply-chain certified says nothing about the degree of *displacement* in the market caused by consumption of that quantum, and the effects of that displacement on the environment. For example, if the Phillips 66 refinery were to process 2.5 million metric tons (MMT) of soybean oil per year,[18] it could certify pursuant to CARB's Staff Proposal that every

[17] "NRDC Recommendations for Updates to the Low Carbon Fuel Standard" (June 2023). Accessible at https://ww2.arb.ca.gov/form/public-comments/submissions/4036. ("2023 Comment").

[18] 2.5 MMT is the amount of vegetable oil the Phillips 66 project could consume per year operating at full capacity. J. Martin, "A Cap on Vegetable Oil-Based Fuels Will Stabilize and Strengthen California's Low Carbon Fuel Standard," *Union of Concerned Scientists* (Jan. 30, 2024) ("Martin 2024"). Accessible at https://blog.ucsusa.org/jeremy-martin/a-cap-on-vegetable-oil-based-fuels-will-stabilize-and-strengthen-californias-low-carbon-fuel-standard/#:~:text=The%20California%20LCFS%20has%2C%20since,other%20secondary%20fats%20and%20oils.

barrel of that soybean oil came from suppliers who had not recently cleared forests to grow the soybeans. But that information would have no bearing on the impact of the additional oil crops that would be planted to *replace* some or all of those 2.5 MMT of oil in the food crop market – which could be soybean oil, palm oil, or any combination of fungible oil crops. The planting of those replacement crops may well have devastating deforestation impacts, and merely certifying that the particular oil used by Phillips 66 was responsibly sourced would disclose nothing about such impacts.

The proposal to prohibit credits from palm oil-derived fuels is similarly ineffectual in the face of fungibility and displacement. The problem identified by ICCT and others is not that palm oil is likely to be used *directly* for bioenergy production. Indeed, as CARB Staff acknowledges in the ISOR, the high CI of palm oil production would effectively preclude it from eligibility already. The problem, rather, is that palm oil may well be grown in significant quantities to *replace* the food crop oils such as soybean oil with which it is fungible where the food crop oils are used in large volumes (as they are or will be in the two Bay Area refinery biofuel conversions).

The CARB Staff Proposal fails to take the one step that has the potential to reduce the incidence of palm oil being used as a bioenergy feedstock: requiring supply train tracking for used cooking oil. By requiring tracking only for crop- and forestry-based oils, CARB staff's proposal would exacerbate the existing risk that suppliers will try to pass off virgin palm oil as used cooking oil. This risk is particularly high given that renewable diesel producers are importing used cooking oil – or perhaps purported used cooking oil – from around the world.[19]

CARB's failure thus far to act in a meaningful manner to curb harmful lipid feedstocks is occurring against the background of unexpectedly high bioenergy production and consumption rates and worsening associated impacts, with information continuing to emerge consistent with studies cited in the 2023 Comment. Biodiesel consumption for the first half of 2023 ran well ahead of projections, at a level that CARB modeling did not anticipate prior to 2037. Soybean oil has been a fast-growing feedstock of choice in the renewable diesel industry, prompting

[19] *Ibid. See* ICCT, U.S. Biofuel Demand and the Potential for Used Cooking Oil from Major Asian Exporting Countries, ICCT February 2023, *available at* https://theicct.org/wp-content/uploads/2023/02/US-UCO-potential_fs_final.pdf.

investments in US soybean crush capacity instead of exports of whole soybeans to Asia – creating a high risk that the diverted soybeans will be replaced in Asia by soybeans as the cheapest substitute.[20] Aligned with this trend, the Phillips 66 refinery in Rodeo, a potentially enormous user of soybean oil feedstock, has approached completion of its bioenergy conversion project and is slated to begin production this quarter. This one facility – out of the many potentially supported by the LCFS – could potentially consume roughly half of the soybean oil exports of the entire nation of Argentina, the world largest soybean oil exporter.[21] And in keeping with concerns about these trends, recent analysis suggests that consumption of food crop oils in bioenergy production has already contributed to the global food crisis.[22]

These trends create an urgent need to isolate and analyze the potential impact of these specific trends in oil crop consumption to produce bioenergy. CARB, unfortunately, has not yet done that. The analysis of Alternative 1 lumps together feedstock caps with multiple other different potential policy choices and analyzes them collectively. It is impossible to discern from this collective analysis how specifically feedstock caps would affect indirect land-use change and other potential environmental impacts associated with food crop oil production.

We call on CARB to analyze the carbon and ecological impact of feedstock caps separately and in isolation from other types of policy measures, including but not limited to a re-evaluation of CI scores associated with lipid feedstocks; and develop appropriate caps on such feedstocks based upon that analysis. The analysis must take into account not only direct impacts of consumption of particular volumes of lipid feedstock for energy production, but also the indirect and substitution impacts that result from the fungibility of the lipid feedstocks. All such analysis, including modeling results, should be made publicly available with an opportunity for comment before any decision is finalized.

4. **Staff recommendations continue to provide LCFS credits to projects that use captured CO_2 to stimulate more oil production, at odds with California's climate goals and state law.**

Currently, projects that capture CO_2 and then inject the CO_2 into oil wells to stimulate more oil production – a process known as CO_2-enchanced oil recovery – are eligible for LCFS credits. The Staff Proposal does nothing to change this status quo. NRDC and numerous other parties have urged CARB to eliminate this practice, in line with SB 1314, which finds that incentivizing CO_2-enhanced oil recovery is incompatible with California's climate goals.[23] We continue to ask CARB to end this counterproductive practice by removing LCFS credits for projects that utilize captured CO_2 for enhanced oil recovery.

5. **Continue and Enhance the Electric Transportation Provisions in the LCFS**

The new LCFS should continue providing credits for various types of electric transportation, including electric forklifts and light duty vehicles, and should expand incentives for medium and heavy duty (MHD) charging and electric vessels, aircraft, and off-road equipment. Electric transportation technologies are critical to cost-effectively reach California's climate targets while reducing tailpipe emissions and related impacts to communities, and the LCFS should support their deployment.

EDU Credit Generation

The current structure of credit generation, whereby electric distribution utilities earn credits for residential charging, owners of the charging equipment earn the nonresidential credits, and various parties can earn incremental credits, is appropriate and should remain unchanged.[24] If CARB finalizes the proposed provision for owners of charging stations[25] at non-reserved parking spaces at multi-family residences to become credit generators, CARB should place reliability and consumer protections on these charging stations so that the customer experience is improved compared to today. For example, this could include reporting requirements with protections

---

[23] Senate Bill 1314 (2022), § 2 (codified at Cal. Pub. Res. Code § 3132).

[24] Examples of non-residential credits include charging of light-duty, medium-duty, heavy duty and non-road vehicles away from home, fixed guideway electrification, and fleet charging of vehicles, marine vessels, material handling equipment, aircraft and similar non-road equipment.

[25] Or their designee such as a charging station provider or operator

against exorbitant charges on EV drivers (i.e., maintaining low operating costs), as well as a high degree of uptime.

We support many of the new proposed provisions on electric distribution utilities (EDUs), but recommend a few changes. While under the proposal, different EDUs are likely to offer LCFS rewards to reduce the purchase or lease price of new and used EV purchases for low-income individuals, EDUs should be required to have the identical eligibility rules in order to minimize confusion for consumers. The proposed five percent cap on administrative costs is premature, particularly for programs focused on outreach to under-served communities, and should instead look to the CPUC definitions and percentages. For example, the current ten percent cap could continue, with the regulatory amendments allowing the Executive Officer to lower it after workshops to examine the details (e.g., impact on small vs large EDUs, impact of credit prices, fixed vs. variable costs, and role of marketing, education and outreach on programs). We also recommend incentives be provided to encourage smaller EDUs to opt into the LCFS so that all areas can be served.

Medium and Heavy-Duty Fast Charge Infrastructure Program

We support many of the provisions in the proposed MHD Fast Charge Infrastructure (FCI) program. Unfortunately, the program rules are inadequate to maximize the potential business case for infrastructure, including near-term use cases such as drayage, short-haul and delivery trucks. While public charging locations are the focus of the MHD FCI program, more favorable rules are needed to help shared depots and fleets which struggle to find grid capacity, favorable zoning, permissive leases and sometimes land. Specially, LCFS should allow locations anywhere in California especially for shared depots, or within 5 miles from a corridor rather than just 1 mile. Sites should be able to have a mix of charging levels to meet different customer needs and be as large as 15 MW. Sites should also be allowed to be as large as 100 connectors to allow for future scaling as seen on the light-duty charging infrastructure side. Single fleets should also receive the same credit formula as public locations and shared depots. Finally, we also recommend the proposed cap on prior quarter deficits be raised to 5% based on the California

Energy Commission's analysis.[26] In this nascent stage, we need to focus more on near-term use cases. CARB has time to do course corrections in a few years in the next LCFS rulemaking.

Light-Duty Fast Charge Infrastructure Program

The LCFS has helped to spur the build-out of the initial, public-access fast-charging infrastructure needs for passenger vehicles as the state transitions to 100% Zero Emission Vehicle requirements by 2035. Based on discussions with numerous charging infrastructure providers, the FCI provisions have been critical for improving the business case for public fast charging stations. But we must continue to scale up public-access to charging infrastructure even more quickly. The FCI provisions that provide capacity credits for direct current fast charging (DCFC) for light-duty (LD) vehicles under the current program rules (e.g., cap of 2.5% of prior quarter deficits, 2.5 MW sites and locations statewide) should continue to 2035. The proposed LD FCI program ending in 2030 (e.g., cap of 0.5% of prior quarter deficits, four chargers per site, 1 MW per site and limited locations) should be rejected. Reliability and interoperability requirements should be added as soon as possible.

Including Other Categories of Electric Transportation

Finally, CARB should allow more types of electric transportation technologies to earn credits in the LCFS. Currently other fuels can earn credits for most end-use applications, but many types of electric vessels, aircraft, and off-road equipment cannot because they lack an approved Energy Economy Ratio ("EER"). Companies investing in emerging electric technologies, many of whom are start-ups, do not have the expertise and funds to go through the detailed application to CARB for an EER. The solution is for CARB to establish conservative default EERs (e.g., 3.0) in LCFS Table 1 that can be used by these emerging electric transportation technologies. This default set of EERs would incentivize electrification in hard-to-reach electric transportation applications such as mining equipment, agricultural equipment, forest equipment, boats, marine vessels,

[26] According to the CEC's AB 2127 analysis, the state will need about 11,600 MW of MHD charging by 2030. See https://efiling.energy.ca.gov/GetDocument.aspx?tn=247323 for November 2022 CEC workshop for more detail. We believe the proposed MHD FC program with deliver less than 1/10th of that need. The sum of the total MHD charging capacity based on this forecast was calculated to be 2,900 MW and 11,600 MW by 2025 and 2030, respectively, by taking the sum-product of the number of chargers and their respective power rating. See AATE primary scenario, Appendix H, Table H-1.

ferries, aircraft, locomotives, tow-tractors, sweepers and other off-road equipment. In addition, because a 3.0 EER is not optimal, some industries would still be motivated to submit an application to CARB in order to establish a higher, more favorable EER. We are also supportive of excluding from this default EER certain end-uses such as golf carts and indoor sweeper/scrubbers that are already electric. We also support the Earthjustice proposal for changing the fixed guideway crediting so that they receive a larger credit for this type of electric transportation including their pre-2010 projects, and for a “VMT multiplier” for zero-emission transit and school bus projects, as both of these serve a critical public need for priority communities. Supporting the development of clean, electric transportation technologies is essential to meeting California’s climate goals while reducing air pollution and health harm to vulnerable communities.

6. Conclusion

Numerous environmental justice and environmental organizations, alongside hundreds of public commenters, have called on CARB over the past year to improve the LCFS Program in alignment with California’s urgent climate and air quality objectives. The LCFS Program can serve as a critical tool to accelerate the transition to electric vehicles and zero-emissions heavy-duty transportation in a way that delivers meaningful benefits to communities – but only if CARB addresses the distortionary policies that continue to undermine the program.

Board Comments Home

February 20, 2024

Liane M. Randolph, Chair
California Air Resources Board
1001 I Street Sacramento, CA 95814

Via Electronic Submittal

To: Chair Randolph

280.1 The unprecedented speed and magnitude of the expansion of renewable diesel used in California, increasingly made from soybean oil, is harming people, accelerating tropical deforestation and undermining California's climate policies. **We call on the California Air Resources Board to immediately cap the use of vegetable oil-based biofuels and to strengthen safeguards within the Low Carbon Fuel Standard (LCFS) to ensure that the use of biofuels does not directly or indirectly contribute to global food price shocks, agricultural expansion and deforestation.** Capping the use of crop-based biofuels is neither radical nor unprecedented[i], and is urgently required to align the LCFS with California's focus on transportation electrification and ensure that California remains a leader in effective and responsible climate policies.

Fifteen years ago, in the midst of rapid expansion of corn ethanol, more than 170 scientists urged the California Air Resources Board to "include indirect land use change in the lifecycle analyses of heat-trapping emissions from biofuels and other transportation fuels."[ii] The Board listened to the science, and for more than a decade this and other policy decisions effectively prevented large increases in the use of crop-based biofuels in California. But these safeguards are no longer functioning effectively.

In the last few years California's consumption of renewable diesel has outstripped the sustainable sources of waste oils and fats, and is increasingly produced from soybean oil, some of it imported directly from South America[iii]. California is on pace to consume 1.3 million metric tons of soybean oil for fuel in 2023, equivalent to 10 percent of global trade in soybean oil[iv]. As California consumes more of the world's supplies of soybean oil, palm oil cultivation is expanding to replace soybean oil diverted to fuel use.

Three primary reasons the California LCFS requires an immediate cap on the use of vegetable oil-based fuels are:

> **The global poor are at risk:** Use of vegetable oil for fuel contributed to a global food crisis in 2022. The World Food Price Index published by the Food and Agriculture Organization of the United Nations reached its highest level in a quarter century in 2022. Oils were the component of the index with the largest increase, with real prices up 84 percent compared to the 2014-2016 reference. Other factors were primarily responsible for this price spike, but despite the global food crisis, California consumption of renewable diesel increased by 47 percent in 2022 and more than 900 thousand metric tons of soybean oil were used to produce renewable diesel for consumption in California. California should not be bidding against the global poor to fuel its trucks.
>
> **Cropland continues to expand into sensitive ecosystems:** The expansion of soybean and palm oil (to replace soy oil used as fuel) is a major driver of tropical deforestation. Recent analysis finds that annual forest carbon loss in the tropics doubled during the early twenty first century[v]

and that oil palm and soybeans are the second and third largest drivers of deforestation after cattle[vi].

Support for renewable diesel is diverting resources from transportation electrification: Renewable diesel generated 40 percent of LCFS credits reported in the most recent quarter, and the large increase in credits from renewable diesel has depressed LCFS credit prices. Capping the use of renewable diesel and other fuels made from vegetable oil will focus more of the support provided by the LCFS on transportation electrification, which can be scaled up with clear climate benefits and without the harsh tradeoffs associated with vegetable oil and other crop-based fuels.

We therefore urge CARB to cap vegetable oil-based biofuels immediately in this rulemaking. Nothing short of a cap will effectively stem the widespread harms caused by the rapidly growing use of these fuels.

Meaningful safeguards must effectively ensure that the use of vegetable oil or other crops for biofuels does not divert food to fuel uses or expand the footprint of agriculture. California's existing land use safeguards within the LCFS rely on an estimation of land use change emissions developed using complex economic and land use models. More than 15 years of research has not led to a consensus estimate of these emissions. A 2022 study from the National Academy of Sciences[vii] describes the methodological problems arising from combining an attributional lifecycle for fuel production with a consequential assessment of the climate impacts of fuel pathways or policies. A recent Model Comparison Exercise[viii] conducted by the US Environmental Protection Agency highlights the deep uncertainty underlying the modeled climate benefits attributed to soybean oil-based biofuels. *In light of the methodological and modeling challenges with the current approach, more direct safeguards against excessive and damaging diversion of food to fuel use are required to effectively prevent bad outcomes.*

The data makes clear that there is no surplus vegetable oil available in the United States, which is projected by the US Department of Agriculture to become a net importer of soybean oil.[ix] In the global marketplace, as more soybean oil is redirected from food uses to fuel production, palm oil is the largest and fastest growing source of vegetable oil substituting for it in global food markets[x]. Because of this substitution, tracking the chain of custody of the oils used for fuel in California or banning the use of palm oil-based fuels is not an adequate safeguard. A cap on the total quantity of vegetable oil used for fuel is the most effective way to ensure California's LCFS does not contribute to harmful outcomes. While the rapid growth of vegetable oil-based fuels in California is the immediate concern, policymakers in all jurisdictions should develop comprehensive safeguards based on the availability and risks associated with inputs to all types of biofuels to anticipate and address future problems.

Liane Randolph, Chair
California Air Resources Board

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph,

As key stakeholders who support the goals of the Low Carbon Fuel Standard (LCFS) we are writing to urge CARB to add a critical safeguard to the proposed LCFS amendments before the Board considers them for adoption. Specifically, to ensure that the LCFS advances California's climate protection and zero emissions transportation goals, we urge CARB to include a cap on
281.1 the use of crop-based biofuels or lipids for LCFS compliance.

The LCFS has the potential to substantially help California meet its climate goals by accelerating transportation electrification and promoting innovation in the use of waste-based biofuels (such as woody materials removed from California forests to reduce wildfire risks). In the absence of effective safeguards, however, the LCFS could drive a massive increase in biomass-based diesel (BBD) made from soybean oil and other crops, which would undermine the goals of the program.

Until recently most BBD used for LCFS compliance has come from waste fats, oils, and greases, but the supply of these feedstocks is limited. As a result, recent increases in BBD supply to California and expected future increases would mostly be produced from virgin vegetable oils.[1] According to a recent study by University of California researchers, if the LCFS Carbon Intensity (CI) reduction target is increased to 30% in 2030, in the absence of a limit on crop-based biofuels or lipids it is likely that BBD consumption in California will increase to over 4 billion gallons by 2030,[2] more than three-quarters of which would likely be supplied by virgin vegetable oils.

The Initial Statement of Reasons (ISOR) for the proposed amendments to the LCFS acknowledge that reliance on crop-based biofuels could add pressure to convert forests and other land for biofuel crop production.[3] For this reason, the proposed amendments include a ban on the use of palm-derived fuel for LCFS credit generation. The proposed amendments also include a requirement to track crop-based and forestry-based feedstocks to their point of origin. While
281.2 well-intentioned, these guardrails are completely insufficient to prevent the risk of deforestation that CARB acknowledges because vegetable oils are largely interchangeable

[3] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf, at page 32.

global commodities as demonstrated by the strong correlation between the price of palm oil and soybean oil. This means that the very large increase in demand for vegetable oil that the proposed amendments would cause is likely to drive deforestation and related carbon emissions regardless of whether the specific feedstocks used to generate LCFS credits can be traced to existing agricultural land. In short, there is no reasonable policy rationale for excluding the use of palm oil but placing no limits on the use of other virgin vegetable oils.

The U.S. EPA examined this issue in a recent technical study[4] and found that a 1 billion gallon increase in soybean biodiesel demand (far less than the increase the LCFS amendments would cause according to the University of California study) would result in net increases in GHG emissions according to two of the three energy and land-use models they used.[5] The net increase in GHG emissions caused by increased demand for virgin vegetable oil could more than offset the total benefits of the LCFS program according to an estimate by the World Resources Institute.[6]

281.3 The ISOR rejects alternatives that include a cap on lipid biofuels based, in part, on model results that suggest that NOx and PM emissions would not decline as much as under the proposed amendments because there would be more reliance on petroleum diesel rather than renewable diesel. However, more recent research by CARB itself shows that there is no statistically significant difference in PM or NOx emissions between petroleum diesel and renewable diesel when used in New Technology Diesel Engines[7]

Electrification of ground vehicles is the most effective pathway to decarbonization in the transportation system. CARB can accelerate the transition by better harnessing the LCFS towards this end, amongst other reforms. There is too much uncertainty surrounding the net GHG benefits of crop-based biofuels at this time to double down on them,[8] especially when other jurisdictions are looking to adopt LCFS programs of their own and will inevitably look to CARB for design and implementation guidance. Limiting the volume of crop-based biofuels that can be used for LCFS compliance is essential to prevent lock-in of counter-productive compliance strategies, preserve incentives to improve the environmental performance of biofuels that are used for compliance, and focus investment on electrification, hydrogen, and carbon removal strategies that are central to California's pathway to net zero emissions.

Re: *Proposed Amendments to the Low Carbon Fuel Standard*

Mainspring Energy, Inc. ("Mainspring") appreciates the opportunity to submit comments to the California Air Resources Board ("CARB") on the Proposed Amendments to the Low Carbon Fuel Standard ("LCFS") released December 19, 2023. Specifically, we appreciate the development of a biogas book-and-claim pathway under a Tier 2 framework and respectfully request amendments to expand eligibility for biomethane to electric vehicle ("EV") charging as well as transition biogas-to-electricity book-and-claim pathway for EV charging to a Tier 1 pathway to meet help California's/CARB's (e.g. Advanced Clean Fleet) EV deployment goals.

Background on Mainspring

Driven by its vision of the affordable, reliable, net-zero carbon grid of the future, Mainspring has developed and commercialized a new power generation technology —the linear generator— delivering local power that is dispatchable and fuel-flexible. Mainspring's linear generator offers a unique non-combustion capacity and energy solution that simultaneously addresses the critical need of reducing greenhouse gas and criteria pollutant emissions, while also enhancing grid reliability and resilience. Linear generators use a low-temperature, uniform non-combustion reaction that maintains peak temperatures below the levels at which NOx forms (1500°C), resulting in near-zero NOx emissions at all loads – including during start-up. This contrasts with the combustion of a fuel with a non-homogenous flame-front, a process that results in higher temperatures and high NOx emissions. California's South Coast Air Quality Management District recently adopted linear generator-specific requirements in the form of Proposed Rule 1110.3, highlighting the low NOx operation of this technology.[1]

[1] South Coast Air Quality Management District, "Rule 1110.3 Emissions From Linear Generators", Adopted November 3, 2023

Modular and scalable, Mainspring's linear generators can be deployed near load, either customer- or grid-sited, with the ability to immediately generate electricity from a range of renewable fuels – including both 100% hydrogen and ammonia (a hydrogen carrier). Mainspring's inverter-based technology offers a full range of valuable grid benefits including fast (and unlimited daily) starts/stops, a wide dispatch range from minimum to maximum load, quick ramping, and in many cases on-site fuel storage which allows linear generators to firm renewables for short or extended periods of time, thereby facilitating the continued rapid adoption of a reliable renewable energy grid. Our locally-sited linear generators add capacity and resilience to the grid while also providing enhanced flexibility to help avoid renewable curtailment.[2] Finally, by virtue of their modular size (20.5′ x 8.5′ x 9.5′) linear generators are space- and land-efficient and can be sited in load pockets, deferring or completely avoiding expensive transmission and distribution investment.

Comments and Proposed Amendments

Mainspring appreciates the development of the Proposed Amendments to the LCFS and the opportunity to provide our comments and recommendations. **We thank CARB for developing a book-and-claim pathway for biomethane to EV charging, and respectfully request an amendment to**
282.1 **expand the eligibility to allow book-and-claim for biomethane via renewable natural gas and hydrogen (meeting all appropriate deliverability and other requirements) used by offsite systems generating electricity exclusively for EV charging services as well.** Doing so will expand the pool of available low-carbon intensity ("CI") electricity as a transportation fuel that is essential to meeting the growing demand from medium- and heavy-duty fleets – including through CARB's own Advanced Clean Fleet ("ACF") regulation. To further streamline this pathway, **Mainspring recommends that the biogas-to-**
282.2 **electricity book-and-claim pathway for EV charging should be transitioned to a Tier 1 pathway to meet California's/CARB's (e.g. ACF) EV targets.** Enabling low-CI electricity to be used for EV charging more readily facilitates the deployment of charging infrastructure –particularly for medium- and heavy-duty vehicles– that is necessary to meet state, climate, and energy goals.

Specifically, we respectfully suggest the following amendments (underlined) regarding book-and-claim accounting accessibility for biomethane and hydrogen for EV charging pathways.

95488.8(i)(2)

"(2) Book-and-Claim Accounting for Pipeline-Injected Biomethane Used as a Transportation Fuel or to Produce Hydrogen or to generate Electricity. Indirect accounting may be used for RNG used as a transportation fuel or to produce hydrogen or to generate electricity for transportation purposes (including hydrogen that is used either in the production of a transportation fuel or in the generation of electricity exclusively for transportation purposes), provided the conditions set forth below are met:

[2] For additional information on technical specifications and performance benefits, visit https://www.mainspringenergy.com/technology/.

(A) RNG injected into the common carrier pipeline in North America (and thus commingled with fossil natural gas) can be reported as dispensed as bio-CNG, bio-LNG, or bio-L-CNG, or as an input to hydrogen production, <u>or as a fuel source for electric generation for the exclusive purpose of EV charging</u>, without regards to physical traceability. Entities may report natural gas as RNG within only a three-quarter time span. If a quantity of RNG (and all associated environmental attributes, including a beneficial CI) is pipeline-injected in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to natural gas sold in California as RNG no later than the end of the third calendar quarter. After that period is over, any unmatched RNG quantities expire for the purpose of LCFS reporting.

(B) To substantiate RNG quantities injected into the pipeline for dispensing as bio-CNG, bio-LNG, or bio-L-CNG or as an input to hydrogen production, <u>or electric generation for the exclusive purpose of EV charging,</u> the pathway application and subsequent Annual Fuel Pathway Reports must include the following documents linking the environmental attributes of RNG (in MMBtu or Therms) with corresponding quantities of natural gas withdrawn: unredacted monthly invoices showing the quantities of RNG (in MMBtu) sourced and the contracted price per unit; and the unredacted contract by which the fuel pathway holder obtained the environmental attributes.

95488.8(g)(1)(A)(2)

"Biomethane supplied using book-and-claim accounting pursuant to section 95488.8(i)(2) and is claimed as feedstock in pathways for bio-CNG, bio-LNG, bio-L-CNG, hydrogen via steam methane reformation, <u>and electricity generation</u>;"

These amendments enable a wide range of applications to which linear generators can be deployed in meeting CARB's and California's EV deployment goals. As an example, deploying linear generators to immediately power EV charging stations enables fleet operators to utilize biomethane to meet CARB's ACF Rule. The mass adoption of medium- and heavy-duty ("MHD") fleet EVs to meet the ACF Rule necessitates a sizable amount of additional capacity at a time when our current grid strains to meet even existing demand. Currently, utility timelines to install the capacity necessary to power and interconnect MHD projects is multiple years, driven by supply chain constraints arising from the period needed to manufacture and deliver new appurtenant equipment (e.g. the switchgear and transformers necessary to serve this new load), the volume of interconnection applications utilities are receiving, and other factors.

However, California cannot afford to wait for supply chain issues to be resolved, nor interconnection processes to be reformed to meet the ACF Rule. This is especially true for MHD EVs that need significant additions in charging capacity (routinely requiring multiple megawatts for each charging facility) and which are often replacing diesel-powered trucks operating in disadvantaged communities. Linear generators can immediately power EV charging stations, operating as microgrids before utility interconnection, and then serving as biogas- or renewable natural gas-powered clean resilience and flexible load after utility interconnection takes place. Prior to utility interconnection, microgrids can provide immediate power to get charging infrastructure up and running, accelerating the timeline for vehicle electrification and achievement of ACF Rule requirements, while also accelerating the impact of improved air quality for disadvantaged and under-resourced communities. After interconnection, microgrids provide much-needed clean and resilient capacity to the grid while displacing the need for polluting diesel backup generators for use during extreme weather and grid events. Without clean resilience, basic services provided by the growing number of EVs could come to a halt during grid outages.

Conclusion

Utilizing low-CI electricity through book-and-claim accounting can help overcome a range of key barriers to rapidly accelerate the reduction in carbon intensity of transportation fuels for medium and heavy-duty EV fleets. Mainspring appreciates the opportunity to comment on these important Proposed Amendments and looks forward to continuing to collaborate with CARB staff in the future.

Sincerely,

/s/ Serj Berelson

Subject	Proposed Low Carbon Fuel Standard Amendments

Comment

The California Air Resources Board (CARB) has proposed changes to
the Low Carbon Fuel Standard (LCFS) that would remove the
Standard's original exemption for jet fuel. I oppose the proposal
to demerit jet fuel, as SAF production does not currently meet
uptake and an increase in jet fuel prices will negatively impact
283.1 industry, not to mention your entire state in general. Instead, I
support policies that will increase the production and supply of
SAF and policies that will support CARB to identify alternatives t
this proposal through continued industry cooperation and
communication. Of course, if you choose to go ahead and continue
with your proposal, I will be glad to accommodate those aircraft
and businesses that will choose to leave California for greener
pastures.

SAN FRANCISCO BAY AREA RAPID TRANSIT DISTRICT
2150 Webster Street, P.O. Box 12688
Oakland, CA 94604-2688
(510) 464-6000

February 20, 2024

Chair Liane Randolph and Members of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Amendments to the LCFS Program

Dear Chair Liane Randolph and Members of the Board,

The San Francisco Bay Area Rapid Transit District (BART) appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS) program. BART owns and operates an electrified fixed-guideway transit system along with electric vehicle charging at its parking facilities. We have participated in the LCFS as an opt-in entity since 2016 and relies on the revenue created by sales of its LCFS credits to help fund the transit system.

284.1 The LCFS program is a powerful tool to meet the state's climate goals by incentivizing use of fuels with lower carbon intensity and switching to modes of travel such as public transit. The LCFS is one of California's best instruments to get passengers out of cars and reduce Vehicle Miles Traveled (VMT).

BART runs 220,000 trains a year and operates in five counties (San Francisco, San Mateo, Alameda, Contra Costa, and Santa Clara) with 131 miles of track and 50 stations. The vast majority of BART trains are electric, with 100% of its electricity supplied by zero-carbon resources including solar, wind, and hydroelectric generators. Every weekday of 2022, BART prevented an estimated 40,000 car trips and reduced California greenhouse gas (GHG) emissions by 500,000 lbs. CO_2e.

284.2 BART appreciates CARB's efforts to support the price of LCFS credits as transit systems around the country have not recovered from the COVID passenger decline, with the Bay Area being most impacted. BART is coping with severe fiscal issues and relies on the revenue obtained from the sale of LCFS credits. The recent steep decline in credit prices has noticeably impacted BART's budget, which is still hundreds of millions of dollars in deficit.

284.3 We are supportive of most of the amendments issued by CARB staff on December 19, 2023, but one important issue remains unaddressed. BART and several other participants highlighted in written and verbal comments in Fall 2023 that the LCFS crediting process results in a discriminatory approach to electric rail. Namely, pre-2011 fixed guideway systems receive a fraction of the credits compared to post-2010 fixed guideway systems. BART contains a small number of extensions that were built after 2010 and those are granted 4.6 times more credits per kilowatt-hour used than 90% of BART's system that falls into the pre-2011 category.

284.3 cont. This differing treatment is a product of the modeling performed at the beginning of the LCFS program which established a baseline that treated all rail in place at that time as existing, and the rail after as new. New rail was presumed to reduce substantially more VMT than existing rail. However, the reality of an operating train system is that all sections of all-electric rail provide an alternative to driving for passengers. The newer sections of BART rail do not use electricity differently or more efficiently and, as a result, every kilowatt-hour used by the system operates the same as any other. While we understand the original modeling performed, granting different kilowatt-hours different amounts of LCFS credits is not equitable, as nearly all other fuel pathways in the LCFS program do not suffer from this artificial distinction.

Now is the time to remedy this aspect of the LCFS program. Transit systems all over the state are facing severe fiscal issues and the additional LCFS credits could help ameliorate. BART is one of only a few electric transit systems eligible under the program and is by far the largest generator of LCFS credits in that category. And it still receives less than half a percent of the program's credits, thereby having no discernible impact on credit prices.

We appreciate CARB staff taking time to meet and respond to our questions during this process. As follow up to our last meeting, we recognize the request to identify and demonstrate improved efficiency and reductions in VMT since 2011 and will share with CARB staff shortly.

284.4 BART also respectfully requests CARB to reduce the costs of the newly proposed verification system for electric fuel pathways. We recognize the importance of ensuring the legitimacy of LCFS credits but question if the proposed system, with its numerous site visits and annual third-party verifications, could not be simplified. In addition, public agencies like BART have lengthy and burdensome procurement systems and would find it difficult to change auditors every six years.

284.5 Public transit is essential to California's achievement of its climate goals. We urge CARB to establish parity for fixed guideway systems within the LCFS program. We look forward to continuing to work with CARB to help carry out the goals and objectives of the LCFS program.

Sincerely,

Yuliya Shmidt

RE: Comments on the Proposed Amendments to the Low Carbon Fuel Standard Regulation

The California Municipal Utilities Association[1] appreciates the opportunity to provide comments on the Proposed Regulation Order: Proposed Amendments to the Low Carbon Fuel Standard (Proposed Amendments).

CMUA represents California's local publicly owned electric utilities (POUs), which are governed by a board of local officials that are accountable to the communities in which they serve. CMUA's member agencies are committed to maintaining reliable and affordable electric service in a manner that supports the state's climate goals.

CMUA supports the Low Carbon Fuel Standard (LCFS) program as key to reducing greenhouse gas (GHG) emissions from the transportation sector. California's POUs utilize LCFS credit value to develop programs to further promote transportation electrification consistent with the needs of the communities they serve. To best position the LCFS program to continue to promote clean mobility options, CMUA offers the following comments for consideration:

- The LCFS Should Not Require Specific Rate Structures in Order to Generate Base Credits
- The LCFS Equity Requirement for POUs Should Remain at 50%
- The Cap on Administrative Costs and Marketing, Education and Outreach (ME&O) for the Clean Fuel Rewards Program (CFR) Should Remain at 10%
- The Cap on Administrative Costs for Holdback Credit Equity Projects Should Remain at 10%
- CARB Should Clarify the Holdback and Equity Holdback Project Lists

[1] The California Municipal Utilities Association is a statewide organization of local public agencies in California that provide electricity and water service to California consumers. CMUA membership includes publicly owned electric utilities that operate electric distribution and transmission systems. In total, CMUA members provide approximately 25 percent of the electric load in California.

- Projects Supporting Medium- and Heavy-Duty (MHD) Electric Vehicles (EVs) Should Qualify as Equity Projects Irrespective of the Primary Location
- Targeted Education and Outreach Should Remain an Eligible Equity Holdback Project
- Low Volume Credit Generators Should be Exempt from Verification
- Site Visits Should Be Based on an Assessment of Risk

Comments

The LCFS Should Not Require Specific Rate Structures in Order to Generate Base Credits

285.1 Section 95483 (c)(1)(A)1. stipulates that to generate base credits, an electric distribution utility (EDU) "must provide rate options that encourage off-peak charging and minimize adverse impacts to the electrical grid". Currently most medium and large POUs offer rate options to encourage off-peak charging. However, due to the nature of the local communities they serve, some POUs do not face the need to impose such a rate structure. Further, some of California's smaller POUs do not have the infrastructure needed to implement such rates. Maintaining reliable, safe, and affordable electric service is paramount to California's POUs. The rate structure of each POU is developed in a public process, with full approval of each POU's Governing Board. As part of this, each POU considers alternative rate structures as needed. However, if the LCFS regulation continues to require a specific rate option in order to be eligible for base credits, some POUs may continue to not participate or opt-out of the LCFS. Such a result would be inconsistent with California's clean transportation goals.

The LCFS Equity Requirement Should Remain at 50%

285.2 The Proposed Amendments increase the equity spend requirement from 50% to 75%. California's POUs vary widely along a variety of parameters, including local community needs. Each POU develops programs in a public process, consistent with the needs of the local community. As developed, the LCFS has been successful in promoting cleaner transportation options for targeted communities. Additionally, California's POUs are promoting cleaner transportation options in various ways, including public charging options, clean public transit options, and modernizing their local distribution systems. In order to support continued investment in this full array of local solutions, the LCFS program equity requirement should remain at 50%.

The Cap on Administrative Costs and ME&O for the CFR Program Should Remain at 10%

285.3 The Proposed Amendments lower the combined cap on administrative and ME&O costs for the Clean Fuel Rewards (CFR) program from 10% to 5%. Such a change would reduce the ability to manage and promote the CFR program. Making the public aware of programs available to aid the transition to transportation electrification is key to the success of the CFR program and ME&O funding is key to informing consumers of the program.

The Cap on Administrative Costs for Holdback Credit Equity Projects Should Remain at 10%

285.4 The Proposed Amendments reduce the administrative cost cap for equity projects from 10% to 5%. While CMUA understands and agrees with the intent to direct as much funding as possible into project development, reducing the administrative cost cap to 5% of project expenditures could limit the ability of POUs to implement these important programs. The success of such programs can be directly attributed to the efforts to develop and administer the programs. CMUA remains concerned that it is not possible to effectively administer these programs if administrative costs are limited to just 5% of project spending. CMUA agrees with comments offered by the Northern California Power Agency (NCPA), that reducing the administrative cost cap will be particularly difficult for smaller utilities that have fewer resources to support the deployment of EV charging infrastructure. Cutting the administrative cost cap in half further limits the ability of smaller utilities to participate in the LCFS program.

CARB Should Clarify the Holdback and Equity Holdback Project Lists

285.5 CMUA appreciates CARB's proposed expansion of eligible equity holdback and other holdback project categories. However, the inclusion of two separate and non-overlapping project lists within the Proposed Amendments creates confusion. For example, the "Other Holdback Project" list (95483(c)(1)(A)5. b.) omits several project categories found on the equity holdback project list (95483(c)(1)(A)5. a.). Such omission calls into question whether equity projects omitted from the Other Holdback list, when implemented in non-equity communities, could utilize non-equity holdback credit proceeds – even though such projects clearly further transportation electrification efforts in California, consistent with section 95491(e)(5).

For simplicity, CMUA recommends that CARB combine the equity and other holdback project categories into a single list. Further, CARB should clarify that projects from the list benefiting equity communities shall be considered eligible equity expenses. Alternatively, CARB should expand the other holdback list to include all projects on the equity holdback list to provide certainty that these projects are still allowable expenditures.

285.5 cont.

In addition, CMUA recommends that CARB further clarify several project categories. CMUA supports the inclusion of the re-skilling and workforce development project category, with clarification that such a program can be developed pursuant to a workforce development strategy adopted by the POU's Board. This additional flexibility is needed, as coordination with specific agencies may slow development of these programs. Additionally, CMUA supports the inclusion of panel and service upgrades as allowable equity expenses for low-income individuals. While there is an existing project category, listing these expenses will provide greater certainty for directing funds toward these purposes. Finally, CMUA supports combining the two equity project categories covering electric mobility solutions into a single list and clarification that the list is not restricted to EV charging equipment and infrastructure.

Projects Supporting MHD EVs Should Qualify as Equity Projects Irrespective of the Primary Location

285.6

CMUA supports language in the Proposed Amendments that includes an equity project category for MHD infrastructure investments. However, the LCFS regulation should clarify that all MHD infrastructure projects, regardless of location, qualify as equity projects. Irrespective of the primary charging location, pollutants from MHD vehicles significantly impact low-income communities, particularly along transportation corridors and logistics centers. By identifying all MHD electrification projects as equity, the LCFS can further remove pollutants that disproportionately impact these targeted communities.

Targeted Education and Outreach Should Remain an Eligible Equity Holdback Project

285.7

The Proposed Amendments would remove multilingual ME&O as an eligible equity project category. CMUA disagrees with this proposed change. Tailored multilingual education and outreach efforts are crucial to identifying the questions and needs of each community that subsequently inform the effective design of programs and projects that respond to those needs. Such education and outreach efforts may not be tied to specific projects but are significantly different from general marketing and advertising campaigns.

CMUA strongly encourages CARB to maintain a narrower equity project category for direct multilingual education and outreach serving equity communities. CMUA also requests CARB clarify that that non-equity holdback funds may be used to support other ME&O expenses.

Low Volume Credit Generators Should be Exempt from Verification

285.8 Section 95500(b)(2) of the Proposed Amendments stipulates that entities generating fewer than 6,000 credits may defer verification for up to two years. CMUA agrees with NCPA's proposal that entities generating 2,000 or fewer credits per year should continue to be exempt. Such entities are often in remote areas that do not offer sufficient profit opportunities for charging companies to invest in electric vehicle charging infrastructure. This requirement makes it less likely for local public agencies that do not generate enough credits to cover the cost of verification to participate in the LCFS. For this reason, the LCFS should only require verification for entities generating credits above a determined threshold.

Site Visits Should Be Based on an Assessment of Risk

285.9 The regulatory requirements for site visits should be modified to stipulate that a verifier should only conduct a site visit if such a visit is warranted by a reasonable concern about data accuracy following a risk assessment. A broad mandate to require site visits to all covered chargers, including residential chargers, is not practical. Additionally, the regulation should be modified to differentiate between fuel pathways. For example, EV charging equipment is already subject to accuracy regulations. Requiring site visits, without a desk review of potential risk, would not provide value for the cost.

<u>Conclusion</u>

CMUA appreciates the opportunity to provide these comments on the LCFS Proposed Amendments. CMUA looks forward to collaborating with CARB and other stakeholders in the LCFS proceeding.

Respectfully submitted,

Dear Low Carbon Fuel Standard Program staff,

We commend you for your excellent work on the proposed amendments to the Low Carbon Fuel Standard (LCFS) Program. The Governor's Office of Planning and Research (OPR) is leading the state's Woody Feedstock Aggregation pilot program to establish reliable access to woody feedstock sourced from California's forested lands and to enhance community fire resilience. With this letter, we provide comments on the role of woody biomass feedstocks in the proposed LCFS amendments and their potential role in supporting the state's decarbonization goals.

Background

The 2022 Scoping Plan identified the need for expanding the use of woody biomass residue, particularly from forest and agricultural residues, as necessary for achieving carbon neutrality by 2045. This is because biomass conversion into energy products, such as clean hydrogen with carbon capture and sequestration, can provide carbon removal needed to compensate for residual emissions remaining in the economy beyond midcentury. Non-combustion technologies (i.e., gasification, pyrolysis) can also provide clean, non-fossil fuels for decarbonizing aviation, shipping, and other hard-to-abate industries.[1,2] Additionally, State-sponsored research has identified biomass conversion to liquid and gaseous transportation fuels as a key option for improving forest health and addressing the wildfire crisis.[3]

A robust innovative wood products market is needed to increase forest management and restoration in California and drive biomass residue utilization at the scale necessary to meet the state's ambitious climate goals.[4] The state has developed a number of market and technology development programs, including a grant program administered by the Department of Conservation that supports carbon-negative hydrogen and liquid fuels sourced from forest biomass. The Infrastructure and Economic Development Bank currently administers a public loan fund to support forest biomass management and

utilization projects. The Department of Forestry and Fire Protection also administers a grant program to enhance wood utilization and bioenergy projects.

As a matter of practice however, biomass utilization projects have been difficult to launch. A key barrier to achieving this vision, that we have learned as part of implementing the pilot program at OPR, is a lack of a recurring revenue incentive for prospective project developers. LCFS is a policy tool that has the potential to support the development of woody biomass residue utilization projects because it can provide recurring incentives for these earlier stage projects. We provide recommendations on the proposed 2024 LCFS Program amendments that could ease the barriers for prospective biomass utilization projects.

Forest biomass

CARB is proposing to include Tier 2 pathways that utilize feedstocks from small-diameter, non-merchantable forest residues removed for the purpose of forest fuel reduction or forest stand improvement, as eligible to receive a reduced carbon intensity (CI) score under the LCFS Program.

This would be a positive change for prospective projects; however, this is unlikely to be sufficient to drive residue utilization consistent with the Scoping Plan. California currently produces tens of millions of tons of forest and agricultural waste annually that are typically left to decompose or be open burned, resulting in substantial emissions of greenhouse gases, criteria air pollutants and precursors. These impacts are anticipated to worsen as the state seeks to increase its wildfire prevention treatments to one million acres per year.

286.1 One suggestion, based on feedback from OPR's regional pilots, is to develop further guidance about how to more comprehensively evaluate the full emissions profile (e.g., emissions benefits from avoided pile burning, decay, etc.) for fuels created using biomass waste feedstocks, particularly forest and agricultural residues. It is currently unclear what an acceptable lifecycle assessment looks like for biomass waste-to-fuels pathways under the Low Carbon Fuel Standard. This uncertainty limits the ability of prospective developers to acquire credits.

Crop- and forest-based feedstocks

CARB is proposing to include third party–certified sustainability requirements for crop- and forest-based feedstocks used in LCFS fuel pathway applications. This would be useful for minimizing unsustainable or illegal forestry practices and improving the transparency and accountability of biomass feedstock supply chains.

Crop-based fuel production in the United States and globally has been identified as having potentially significant indirect global land use impacts, including deforestation and competition with food production .[5] More broadly, there is significant uncertainty in the

[5] California Air Resources Board. Low Carbon Fuel Standard Public Workshop: Potential Regulation Amendment Concepts. February 22, 2023. https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/lcfs_meetings/LCFSpresentation_02222023.pdf

ability to estimate the complete lifecycle emissions from crop-based biofuels.[6] There is also a risk that fuels produced from out-of-state crop-based feedstocks may compete with in-state waste feedstocks that are needed to address catastrophic wildfire. CARB should consider stricter requirements on crop-based fuels production given these inherent risks. We outline alternatives that would avoid perverse sustainability outcomes and encourage high-quality biomass waste utilization projects in California.

286.2

- *Prioritizing in-state biomass waste feedstocks*. CARB could consider options that prioritize biomass waste feedstocks sourced from within California. Prioritizing in-state biomass waste pathways under the LCFS Program would maximize the climate, air quality and local economic benefits of converting waste sourced from state lands.[7] For example, CARB could feasibly offer targeted incentives for fuel pathways that specifically use residues from fire management or forest restoration activities on California's forested lands.[8]

286.3

- *Cap on crop-based fuels*. CARB could consider placing a cap on crop-based fuels to avoid the proliferation of fuels pathways from out-of-state crops. Renewable diesel pathways under the LCFS Program have historically utilized waste fats, oil, and grease as the primary feedstock. However, these feedstocks are currently supply-limited.[9] Additionally, CARB anticipates an increase in renewable diesel consumption by 2025.[10] There is a risk that renewable diesel under the LCFS Program could become increasingly reliant on crop-based feedstocks such as soybean and other virgin vegetable oils.[11] The implication here is that an increase in demand for crop-based biofuels could feasibly incentivize the conversion of productive farmland into bioenergy crops and lead to deforestation.

Alternative jet fuel

286.4 CARB is proposing to require intrastate fossil jet fuel to comply with the LCFS Program starting in 2028. This would be an important change as the state's aviation sector contributes nearly 38 million tons of carbon dioxide–equivalent per year, an amount which exceeds that of all the oil refineries in the state. Biomass waste will be an important

Subject: Low Carbon Fuel Standard – Incentives for Light Duty Vehicles, Base Credits and Verification Requirement EV Data

BMW of North America, LLC (hereafter BMW) is pleased to submit comments to the proposed amendments to the Low Carbon Fuels Program (LCFS) - Clean Fuels Reward Program. BMW values the partnership and shared goals we share with the state to grow the ZEV market, reduce carbon intensity in fuels and increase consumer awareness. Recently, BMW a along with six other automakers, announced the launch of a new entity IONNA, to build out 30,000 high-powered EV chargers across North America. The goal is to make fast charging accessible, convenient, and reliable. BMW remains committed to invest in the ZEV market and to work cooperatively with all critical stakeholders.

BMW supports the comments of Auto Innovators. BMW is a longtime supporter of the LCFS program and believe that consumer incentives are still necessary to grow the light-duty market. We urge CARB to reconsider the current amendment that will direct critical incentives away from light-duty vehicles to medium and heavy-duty vehicles. The market is in a critical phase as we transition consumers to electric vehicles and look ahead to meet the state's ZEV goals and greenhouse gas targets. While California is leading the nation in the ZEV market, more is needed. Consumer education, investment in infrastructure, and consumer incentives will remain key drivers to transition California's fleet.

Base Credits

287.1 We believe that CARB should allocate part of the base residential credits from EV charging to automakers. OEMs are uniquely positioned to use this revenue to provide benefits in support of EV adoption. OEMs can move fast to execute programs, increasing the benefits from this spending. Splitting this revenue between OEMs and IOUs will provide new opportunities for collaborating between the two industries, unlocking opportunities for the electric vehicle space. This is particularly important now, as both industries are exploring how to accelerate the adoption of smart charging, public infrastructure development, and bidirectional charging.

Verification Requirement for EV Charging Data:

287.2 CARB proposes adding third-party verification requirements for electric vehicle charging data used to generate incremental LCFS credits. We ask that CARB implement simple verification requirement that are cost-efficient for voluntary credit generators. The data provided by these voluntary credit generators is valuable to CARB and utilities, as it is used to determine the amount of base credits that are generated. Costly verification requirements may disincentivize participation by EV charging entities, which would deny CARB and the utilities of vehicle data important to the LCFS program. As this data is beneficial to utilities for the generation of base credits, the cost of

287.3 verification should be shared with utilities. Additionally, we ask that CARB consider how verification processes can be implemented such that does not involve the use of personally-identifiable data.

Participation from Small Dairy Farms
BMW has partnered with dairy farmers as part of our participation in the LCFS program. Dairy farms can generate renewable energy through the application of biodigesters, which generate renewable by capture methane emissions from cow manure at these farms. Not only do biodigester systems create renewable energy, but they also reduce methane emissions that would otherwise occur at the farm, resulting in substantial carbon emission reduction opportunities.

Through our work with multiple dairy farms of different sizes, we have come to recognize that the current LCFS program rules significantly disadvantage small dairy farms. The LCFS rules require complex verification and data reporting requirements that are not financially feasible for small dairy farms, given relatively small energy generation for these projects. In order to support the participation of small dairy farms, we recommend that CARB make the following rule changes specific for dairy farms with biodigester systems under 150 KW:

287.4

- **Simplified Lookup Table for small biodigesters.** For small facilities looking for a simple way to participate in the LCFS, CARB could offer a Lookup Table Pathway option, with a fixed CI score set at the lower of the score of the highest currently approved dairy manure to electricity fuel pathway in the program. After ensuring that facilities meet minimum eligibility criteria, projects would then be able to be approved for immediate participation into the program. Projects that want to pursue a higher score would have the
287.5 option of going through the full verification process, allowing CARB to evaluate the efficiency of projects that claim larger emission reductions.

- **Eliminate 3rd Party Verification requirements.** The requirement to have a Third-Party
287.6 Verifier review the annual fuel reports represents a significant cost for small biodigesters and prohibits the participation of more small dairies, limiting LCFS to only the largest biodigesters. Eliminating this requirement will allow more small farms to participate in the program.

287.7
- **Simplify the Annual reporting requirements.** Reducing the data requirements for small farms would eliminate a substantial cost barrier facing small farms.

Thank you for considering BMW NA's comments during this rulemaking. We look forward to working with CARB staff and board members. Please feel free to reach out with any questions you may have.

Sincerely,

Manfred Grunert

California Air Resources Board
1001 I Street
Sacramento, California 95814

Re: California Bioenergy's Comments on the Low Carbon Fuel Standard Rulemaking Package

Dear Ms. Sahota,

Thank you for the opportunity to provide these comments to California Air Resources Board (CARB) relating to the Low Carbon Fuel Standard (LCFS) Rulemaking Package released on December 19, 2023. California Bioenergy LLC (CalBio) is appreciative of CARB's efforts over the past several years to develop the LCFS program into becoming one of the most impactful policies to support the transition from petroleum to clean fuel alternatives. There are few programs in the world which can boast the significant decarbonization of the transportation sector through sound science and policy. We write these comments with the notion that the climate emergency demands CARB strengthen the program to support achievement of California's legislatively-mandated greenhouse gas (GHG) reduction targets.

Founded in 2006, CalBio works closely with California dairy farm families, dairy co-ops and cheese producers, CARB, the California Department of Food and Agriculture (CDFA), the California Public Utility Commission (CPUC), the California Energy Commission (CEC), and the U.S. Environmental Protection Agency (EPA). We exist to reduce methane emissions and are committed to enhancing environmental sustainability for all Californians. CalBio's digester projects produce clean renewable natural gas and generate electricity, both used as a vehicle fuel to power low-emission trucks, buses, and cars thereby replacing petroleum-based fuels—diesel, gasoline, and natural gas. Our projects reduce GHGs, improve local air quality, create jobs in disadvantaged communities, and provide a new revenue stream along with other meaningful benefits to our dairy partners.

In our comments below, we suggest practical and necessary revisions which serve to improve the LCFS program in its ambition to reduce GHG emissions and implement a successful program.

1. **Addressing the Near-Term Credit Bank Surplus**
2. **Allow for Book & Claim of RNG to Off-site Electric Generators**
3. **Revise the True-Up Language to Apply to Temporary CI Scores**
4. **Establish a Temporary CI for Dairy Biogas to Electricity**
5. **Grandfather Existing Pathways Certified under GREET v3.0**

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

1. **Addressing the Near-Term Credit Bank Surplus**

288.1 As of Q3 2023, the LCFS credit bank has swelled to more than 20.5 million credits, largely driven by growth in renewable diesel, electricity, and biomethane. The program has become a victim of its own success and now overcompliance threatens to stifle investment making it uneconomic to build new projects under the current market conditions. CalBio appreciates CARB's recognition of this problem by introducing both a near-term step down in the CI target in 2025 and the introduction of an Automatic Acceleration Mechanism (AAM). We believe these are fundamental concepts to bring down the LCFS credit bank surplus, however, they simply do not go far enough. Fortunately, there exists an extraordinary opportunity to increase ambition and ultimately achieve more GHG reductions by strengthening the near-term step down and enabling the AAM to begin one year earlier. Both actions will work in tandem create the near-term price signal necessary to drive investments in GHG reductions now and enable a faster, more dynamic response to changing market conditions, and help to achieve a CI reduction beyond the stated target of 30% by 2030.

288.2 The primary lever at CARB's disposal to have the most immediate impact in driving down the LCFS credit bank is to first increase the near-term step down from 5% in 2025 to at least 10%. Notably, as part of the proposed amendments, the diesel benchmark for years 2025 through 2045 has been revised from 100.45 gCO2e/MJ to 105.76 gCO2e/MJ from a 2010 base year which substantially reduces the impact of the originally proposed 5% step down in the diesel pool. For the proposed step down to be meaningful, an 10% or greater step down is required and that the increased step-down be propagated through the stringency curve translating into a revised 2030 target (e.g., a step down of 10% translates into approximately a 35% reduction in the CI in 2030 relative to 2010).

288.3 Another specific way to address the near-term credit bank surplus is to revise AAM to be triggered in 2026 based on 2025 credit bank data and increase the CI stringency target in 2027. As currently proposed, it will not kick in until 2028 based on 2026 data. However, if the proposed near-term step down, even if increased to 10%, is insufficient to draw down the credit bank, the AAM should be triggered provided the eligibility requirements are satisfied. Postponing the AAM by an additional year will undermine its ability to serve its intended purpose which is to guard against an oversupply of credits.

288.4 CalBio proposes CARB increase the 2030 CI target to at least 35%. This is one of the scenarios that CARB has been workshopping since 2022 and is the one which is expected to achieve the highest levels of GHG reductions[1]. A study from ICF found that the LCFS could accommodate a carbon intensity target of 41-44%[2]. Increasing the stringency to drive GHG reductions is in alignment with the 2022 Scoping Plan for Achieving Carbon Neutrality (2022 Scoping Plan)[3] which lays out a path to achieve targets for carbon neutrality and reduce GHG emissions by 85 percent below 1990 levels by 2045. The actions described

Visalia, CA 93292
559-667-9560

288.4 cont. above are necessary to give confidence to investors that new projects can be built and allow for greater GHG reductions to be achieved.

2. Allow for Book & Claim of RNG to Off-site Electric Generators

288.5 An important opportunity for CARB to incentivize additional GHG reductions is to expand the language in §95488.8(i)(2) to allow for the book-and-claim of pipeline-injected biomethane to be used to generate Low-CI electricity as a transportation fuel. Currently, CARB recognizes electricity as a transportation fuel in §95482(b) and moreover in §95488.8(i)(1) recognizes that "Low-CI electricity used as a transportation fuel can be indirectly supplied through a green tariff program…or other contractual electricity supply relationship." This is achieved by REC-matching, where the reporting entity must demonstrate that the low-CI electricity is supplied through book-and-claim accounting to electric vehicle charging provided "that any renewable energy certificates associated with the low-CI electricity were retired in the WREGIS for the purpose of LCFS credit generation" (see §95491(d)(3)). However, in the context of electricity derived from low-CI dairy biogas, this pathway requires the RECs to be created from a generator co-located with the digester.

Given the recognition CARB has for 1) book-and-claim of Low-CI electricity production to be matched to electric vehicles, and 2) RNG injected into the commercial distribution pipeline and withdrawn at a CNG station in California, CalBio argues that by the same logic, RNG injected and withdrawn via book-and-claim should qualify for the purposes of generating electricity. In this construct, RECs generated from an electric generator located off-site from the dairy powered by gas fed through the utility pipeline should similarly be allowed to match RECs to electric.

This approach aligns with CARB's existing book-and-claim accounting framework and greater GHG reductions could be realized by making this targeted change to the regulatory text that is in keeping with CARB's objectives of supporting the transition to zero emission transportation. As noted, this recommendation is fully aligned with CARB's goals expressed in the Initial Statement of Reasons (ISOR), page 4, which states:

> *"This regulatory update proposal, which is described in detail in this staff report, is focused on the following key concepts:*
>
> - *Increasing the stringency of the program to reduce emissions and decarbonize the transportation fuel sector, which will also aggressively reduce our dependence on fossil fuels;*
> - *Strengthening the program's equity provisions to promote investment in disadvantaged, low-income and rural communities;*
> - ***<u>Supporting electric and hydrogen truck refueling;</u>***
> - *Incentivizing more production of clean fuels needed in the future, such as low-carbon hydrogen;*

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

- ***Supporting methane emissions reductions and deploying biomethane for best uses across transportation;*** *(emphasis added)*

Further on page 6 of the ISOR, it states:

288.5 cont.

> *"The purpose of the LCFS regulation is to reduce the carbon intensity (CI) of transportation fuels used in California, thereby reducing GHG emissions, and to **incentivize the production of low-carbon and renewable alternatives, such as low-CI electricity** and renewable hydrogen, and biofuels to displace fossil fuels and allow more energy security in the transportation sector." (emphasis added)*

Further on page 30 of the ISOR, it states:

> *"**Biomethane can play a key role in decarbonizing stationary sources** or other energy applications, and the 2022 Scoping Plan Update identifies additional end uses in the industrial, commercial, and residential sectors; production of hydrogen; and **electricity generation by displacing the need for fossil gas.**" (emphasis added)*

CARB would be remiss to lose this opportunity to encourage and incentivize low-CI dairy biomethane to be used for electricity generation. This will create an additional market for RNG derived from dairy biogas, as CARB has signaled it is seeking to phase it out of combustion in CNG vehicles and "direct biomethane to sectors that are hard to decarbonize or as a feedstock for energy."[4] Directing RNG as a feedstock to electricity production is a readily available solution and further encourages grid resiliency which will be necessary as electric vehicle charging scales in the state.

3. Revise the True-Up Language to Apply to Temporary CI Scores

288.6

CalBio is appreciative to CARB for proposing a credit True-Up after provisional certification and recognizing the real GHG reductions that have occurred when a project's CI score decreases. Unfortunately, this approach fails to recognize, perhaps more importantly, the true GHG reductions that should be credited once the provisional certification is achieved relative to the GHG reductions credited while operating under the -150 CI Temporary Pathway for dairy digesters. It is unclear why CARB deviated from this approach in the proposed rule, particularly when it was workshopped in 2022 during which time it proposed *only* adjusting the temporary CI score and did not contemplate adjustments for subsequent verifications.[5]

A key point raised in those workshops was the idea that a True-Up would ease the pressure for CARB to review pathways and alleviate concerns with delays in certification. Considering CARB staffing shortages

---

[4] https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf
[5] https://ww2.arb.ca.gov/sites/default/files/2022-08/August%202022%20Workshop%20Slide%20Deck%20Presentations.v16.pdf

2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

288.6 cont. leading to pathway review times often exceeding 18 months from the time they are submitted, it would be in CARB's own interest to give itself the necessary time to review projects without unfairly discounting legitimate GHG reductions for delays outside the project's control. The Temporary CI has been conservatively set to -150 gCO2e/MJ, this can cost a project millions of dollars while waiting for a return on investment. If this issue is left unresolved, it further poses risks to future investment in projects and reduces the potential for additional GHG reduction opportunities. CARB should be taking steps to encourage development, and credit projects appropriately in the interest of fairness and reflecting true environmental performance.

4. Establish a Temporary CI for Dairy Biogas to Electricity

288.7 It is of great concern to CalBio that no Temporary CI exists for Dairy Biogas-to-Electricity pathways has been established in the LCFS since the program's inception and that CARB has not sought to correct for this in the proposed amendments. The failure to include this provision discriminates and disadvantages in-state dairy digester projects which contribute to California's SB 1383 goals and provide renewable electricity as a grid resource and transportation fuel. As referenced in the ISOR and quoted in CalBio's comments under topic #2 above, one of the *primary purposes* of the LCFS regulation is to incentivize the production of low-carbon and renewable alternatives, such as low-CI electricity.

CARB should correct this oversight given dairy biogas-to-electricity pathways fully reduce methane in the same manner as dairy biogas-to-RNG pathways and thus should be treated equally. Project economics for dairy biogas-to-electricity are generally more challenging than RNG projects given they are currently not eligible to participate under the RFS program or BioMAT. Failure to allow electric projects to receive a Temporary CI score further exacerbates the concerns expressed in CalBio's comments under topic #3 by preventing beneficial projects from receiving revenue until the provisional certification is achieved, a process which can last several months to years.

It should be noted that CalBio has made significant financial investments in cleaner electricity generating technologies such as Bloom Fuel Cells and Mainspring Linear Generators which convert methane into electricity without combustion. These technologies should alleviate concerns around NOx emissions associated with internal combustion engines. CalBio would be supportive of CARB unlocking the Temporary CI for dairy biogas-to-electricity if it meant requiring the use of a non-combustion technology such as a fuel cell or linear generator.

5. Grandfather Existing Pathways Certified under GREET v3.0

288.8 CalBio is proposing CARB consider grandfathering in pathways which have already been certified under GREET v3.0. These pathways have already undergone public review and comment period and should remain under models which they have been validated and verified through the end of their crediting

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

288.8 cont. periods. It would be administratively burdensome to deviate from the modeling that has been established for existing pathways and require unnecessary adjustments to the information CARB and 3rd party verifiers have already reviewed and approved.

CalBio commends CARB for developing the LCFS as the nation's leading and most successful example of a market-based carbon reduction program for the transportation sector. We thank you for considering these comments.

Sincerely,

Andrew Craig

RE: CalBio Comments on CARB's Proposed Tier 1 Simplified Calculator for Biomethane from Anaerobic Digestion of Dairy and Swine Manure released December 19, 2023

Dear Ms. Sahota,

Thank you for the opportunity to provide comments to the California Air Resources Board (CARB) on the proposed Tier 1 Simplified Calculator for Biomethane from Anaerobic Digestion of Dairy and Swine Manure released December 19, 2023.

California Bioenergy LLC (CalBio) is a leading developer of dairy digester projects. Founded in 2006, CalBio works closely with California dairy farm families, dairy co-ops and cheese producers, CARB, the California Department of Food and Agriculture (CDFA), the California Public Utility Commission (CPUC), the California Energy Commission (CEC), and the U.S. Environmental Protection Agency (EPA). We develop projects that reduce greenhouse gas (GHG) emissions, improve local air quality, protect water quality, and create local jobs. Our projects produce renewable natural gas and generate electricity, both used as a vehicle fuel to power low emission trucks, buses, and cars.

CalBio has extensive experience working with the Tier 1 Simplified CI Calculator for Biomethane from Anaerobic Digestion of Dairy and Swine Manure (DSM CI Calculator). With over 30 certified Tier 2 pathways, we have developed expertise in both using and understanding the complexities of this tool. In addition, both our in-house staff and consultants are skilled greenhouse gas (GHG) accountants that value incorporating the latest climate science and emission factors into the DSM CI Calculator analysis framework and our project pathways. CalBio is thankful for the opportunity to share our feedback on the proposed updates and commends CARB on implementing changes that will make the DSM CI calculator more streamlined, require less user modifications, and reflect the latest industry standards for GHG accounting.

A. Tier 1 Simplified CI Calculator for DSM Biogas-to-Electricity Pathways

CARB supports the electrification of the transportation sector in California and seeks to build more electric projects to help CARB meet goals of the Scoping Plan[1] and serve the growing demand for electric

[1] https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

289.1 vehicles. Thus, CalBio strongly recommends that CARB develop a separate DSM biogas-to-electricity Tier 1 CI Calculator for such pathways to streamline the process for reviewing and approving biogas-to-electricity projects. The proposed CI Calculator would inherently include all the modifications and technical guidance included in CARB's LCFS Guidance 19-06 document. Absent a standard Tier 1 CI Calculator for biogas-to-electricity, all such projects will be forced into a Tier 2 application. This disadvantages in-state projects which help California to achieve its methane reduction goals and support electrification.

Based on our experience building the first dairy biogas-to-fuel cell project and successfully achieving pathway certification for the low-CI electricity produced by this project, CalBio also proposes the following modification for this new CI calculator:

- 289.2 CalBio recommends updating the guidance that CARB issued in LCFS Guidance 19-06 document to divide the final biogas electricity CI by the efficiency of the electric generator used in the project. The approach appears to introduce a cap in the CI value when the engine efficiency exceeds the 50% benchmark. When the CI is divided by a higher efficiency value, it effectively penalizes the project for being more efficient. CalBio proposes using the benchmark efficiency instead, which allows the credits to remain linear with increased generator efficiency. The CI calculator already caps avoided methane crediting based on either the lesser of biogas produced and the modeled emission reductions. It does not seem reasonable to further cap based on efficiency, especially when CARB's motivation has been to encourage projects to use more efficient and cleaner fuel cell technology.

  Suggested Modification: *In Cell E91 of the "Manure-to-Biogas" Worksheet, the formula for the Final Electricity CI for the 2018 CARB-modified electricity calculator should be: =IF(W52=0,0,(G68+G75+G88+G89+G90)/(IF('EF Table'!E89>0.5,'EF Table'!E91,'EF Table'!E89))). An equivalent formula should be added to a 2024 DSM biogas-to-electricity Tier 1 CI Calculator.*

B. Proposed DSM Biomethane CI Calculator

289.3 Please see below for CalBio's feedback on and additional recommendations for the Proposed DSM Biomethane CI calculator.

'Biogas-to-RNG' Worksheet

- **Field 2.7 Flared Biogas Biomethane Content:** The proposed calculator does not appear to include an emissions factor for the newly added Flared Biogas field in the LCFS pathway system boundary or resulting CI calculations. To solve this, CalBio proposes applying the same emission factor used in Sections 2.20 and 2.30 to apply to the CO2 emitted from the combustion of biogas based on the inputs to Sections 2.6 and 2.7. CalBio believes flared biogas at the digester should be treated consistently with how flared biomethane is accounted for at the upgrading facility, and the resulting emissions should be included in the LCFS pathway system boundary regardless of the biogas handling method (i.e., flaring or venting). The project should also demonstrate the flare was operational through a thermocouple or other instrument to demonstrate the gas was

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

truly combusted. In the absence of operational data demonstrating combustion, the biogas flow should be treated as vented.

Suggested Modification: *Include an Emission Factor calculation in Cell F57. Also include row in the Raw Biogas Production-Digester in Section 4 to include "Biogas (flaring)".*

- **Field 2.22 On-Site Electricity from Biogas (upgrading and compression):**
    - 289.4 CARB has emphasized its goals for producers to choose more efficient, cleaner technologies for on-site power generation. In alignment with these goals, CalBio recommends that CARB recognize the biogenic nature of the CO_2 emissions occurring from the combustion of biogas for on-site electricity use. The default emission factor for the use of on-site electricity from biogas (641 gCO2e/kWh) assumes the fuel is fossil-based natural gas and is more than double the default emission factor for grid electricity in all but six of the eGRID regions. Thus, most renewable fuel producers are penalized if they choose to offset some of the power for their facilities using on-site electricity fueled by biogas rather than grid electricity.
    - For facilities that use biogas for electricity production, CARB's Instruction Manual instructs applicants to choose the User Defined Mix electricity option for Field 2.1 Select Regional Electricity Mix, however that User Defined Mix emission factor flows into all the Grid Electricity Fields, rather than the On-Site Electricity from Biogas (Field 2.22). CalBio recommends CARB allow users to select an electricity mix for each electricity field.
    - CalBio also recommends that CARB include a User-Defined Option for electricity generation equipment and associated technology-specific emission factors so users can appropriately model emissions from technologies other than conventional stationary reciprocating engines, such as fuel cells, linear generators, etc. Similar to the guidance issued for User-Defined Fuels in Section 2 of the calculator, applicants can consult with CARB Staff to develop the technology-specific emission factors.

Suggested Modification: *RNG producers which use biogas to generate electricity should be able to replace the Emission Factor calculation in Cell U57 with 0 recognizing that the CO2 emissions are biogenic.*

- **Field 2.6 Flared Biogas Flow (metered)**: User Input cells are formatted as "Percentage," but
289.5 should be formatted as "Number" like Sections 2.4 and 2.8. The formatting of cell E52 could also be updated to use the 1000 separator (,).

'Avoided Emissions' Worksheet

- **Accounting Errors in Cells C45 and C47 for Projects that use Biogas to Generate On-site**
289.6 **Electricity:** If a project seeks to generate on-site electricity from biogas, it is assumed the Biogas in MMBTUs will be entered into "2.20 Raw Biogas (as Process Fuel for upgrading and

CALIFORNIA BIOENERGY
Helping dairies fuel a renewable future
2134 E. Mineral King Ave
Visalia, CA 93292
559-667-9560

compression)" and the electricity generation will be entered into "2.22 On-Site Electricity from Biogas (upgrading and compression)" on the 'Biogas-to-RNG' Worksheet. However, when these values are entered, the "RNG associated with onsite electricity production" is not recognized in Cell C45 in the 'Avoided Emissions' Worksheet. The CI impact should be the same if the electricity is derived from Biogas as opposed to Biomethane.

Similarly, Cell C47 contains a note where CARB recognizes that if on-site power generation is used in the LCFS system boundary, the value of "RNG associated with onsite electricity production" can be included in the avoided CH4 calculation here. CARB should modify these cells to treat on-site electricity derived from biogas consistently since electricity can be generated from both and still be considered within the RNG production boundary.

Suggested Modification: *In the scenario described above, Cell C45 should be revised to the following =('Biogas-to-RNG'!S52+'Biogas-to-RNG'!AE52)/Reference!D16*Reference!E16 and Cell C47 should be revised to equal SUM(C45,C41)/C40*

'Manure-to-Biogas (LOP Inputs)' Worksheet

289.7
- **Field L3.7 Biomethane Content in Vented Biogas (metered)**: User Input cells are formatted as "Number" but should be "Percentage" for consistency with units identified in cell H53.

C. Proposed DSM Biomethane CI Calculator Instruction Manual

Please see below for CalBio's feedback on the Proposed DSM Biomethane CI calculator Instruction Manual.

289.8
- **Table 2, Field L1.(1-6).13 Fraction of Volatile Solids Sent to Anaerobic Storage/Treatment System:** The Description and Instructions for this Field states: "…*For modeling the manure (volatile solids) from more than six livestock categories/sources, please use a separate worksheet to calculate the weighted fraction of manure (volatile solids) average for each livestock category, and use the calculated weighted average as the inputs to Fields L1.(1-6).12*." However, Fields L1.(1-6).12 is the Van't Hoff-Arrhenius factor and is not a User Input. The calculated weighted average be the inputs to Fields L1.(1-6).13.

289.9
- **Table 9, Field 2.1 Select Regional Electricity Mix for Biomethane:** CARB publishes the prior year's grid electricity factors on an annual basis (https://ww2.arb.ca.gov/resources/documents/lcfs-pathways-requiring-public-comments). CARB should explicitly allow applicants to enter the CARB-published values as a User Defined Mix by stating these instructions directly in the Instruction Manual, to more accurately reflect the emissions from electricity utilized at their facilities.

D. Proposed Data Substitution Requirements in § 95491.2.

289.10 CalBio believes the Data Substitution Requirements listed in Table 13 of Section 95491.2 do not appropriately consider the specific types of common data issues often observed by flow meters, methane analyzers, and other equipment used as inputs to the CI Calculator. The requirements are overly prescriptive and overly simplified and do not allow for more nuanced and appropriate data substitution.

First, CARB should specify a definition and a threshold for "Missing Data" where the requirements are only triggered if a certain duration or volume of missing data is observed. For instance, is a single missing 15-minute flow reading considered missing that must follow these procedures? In many cases, it would not make sense to substitute flow using the prescriptive language, especially if the meter totalizes flow and the volume of biogas which flowed through the meter during the data-outage period is known. Durations and volumes which stay under a certain limit should be able to be addressed within the project's data substitution procedures defined it is monitoring plan and subject to verifier review. What CARB is proposing may lead to more Alternate Methods as developers seek to justify why an approach is needed because it does not fit with the prescriptive requirements. Additionally, performing data substitution that is "conservative" for a particular project that exists in a cluster, may affect its gas allocation contribution which may inadvertently credit another project with a greater proportion of biogas production which may not be appropriate or conservative.

289.11 Lastly, the 10 day alternate method submittal requirement is not realistic as there are times when a process change occurred on the equipment or at the farm or in the data that is not observed until after a report is submitted when the project is undergoing verification. By prohibiting alternate methods which are not submitted within the specified timeframe and the outcome be that "no reporting entity may generate LCFS credits associated with the time period for which there is missing data" is not reasonable for something that is potentially de minimus to the integrity of the pathway. CARB and the project applicant should be able to work together to ensure a robust, accurate, and agreed upon approach to support the goals of a well-functioning program.

We would like to thank CARB for the opportunity to comment and we look forward to engaging further on the topics above.

Sincerely,

Andrew Craig

Re: Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Honorable Members of the California Air Resources Board:

290.1 This firm represents the Leadership Counsel for Justice and Accountability ("Leadership Counsel") in matters relating to the California Air Resources Board's ("CARB") Proposed Amendments to the Low Carbon Fuel Standard Regulation ("Proposed Amendments" or "Project"). Central Valley Defenders of Clean Water & Air, Animal Legal Defense Fund, and Food & Water Watch have informed us that they also join in this letter. CARB's adoption of the Proposed Amendments is subject to the California Environmental Quality Act ("CEQA").[1] CARB's Draft Environmental Impact Analysis ("Draft EIA") must therefore: evaluate all reasonably foreseeable impacts of the Proposed Amendments in sufficient detail; adopt all feasible mitigation measures to lessen the severity of the Proposed Amendments' environmental impacts; and consider all feasible alternatives that would achieve the goals of the Proposed Amendments while lessening the severity of the Proposed Amendments' environmental impacts. Public Res. Code §§ 21002.1; 21100. The Draft EIA fails to comply with each of these obligations.

---

[1] CARB acts pursuant to a certified regulatory program which exempts the agency from preparing an Environmental Impact Report ("EIR") because the environmental analysis CARB is required to undertake is deemed the functional equivalent of an EIR. 17 Cal. Code. Regs. §§ 60000-60007; *POET, LLC v. State Air Resources Bd.* (2013) 218 Cal.App.4th 681, 710 CARB's actions are subject to all other applicable provisions of CEQA. 14 Cal. Code Regs. § 15250; *POET, LLC*, 218 Cal.App.4th at 710.

290.1 cont.

As discussed in more detail below, the Proposed Amendments will increase the already significant incentive concentrated animal feeding operations ("factory farms") have to create more Low Carbon Fuel Standard-eligible fuels and expand their operations to increase fuel production. Despite this inevitable effect of the Proposed Amendments, CARB's Draft EIA fails to mention—let alone analyze—the environmental impacts associated with factory farm expansions or anaerobic digestion-related fuel production. The Draft EIA acknowledges that the installation of anaerobic digesters, which are necessary to generate LCF-eligible fuel from manure methane emissions, will have significant environmental impacts. However, the Draft EIA fails to adequately discuss and analyze these impacts, which include impacts to air quality and water quality and adverse public health impacts on communities living in close proximity to factory farms.

In addition, the Draft EIA fails to propose adequate mitigation measures to address the project's impacts and fails to adequately analyze alternatives to the project. These inadequacies require that the Draft EIA be revised and recirculated so that the public and decision-makers are provided with a proper analysis of the project's significant environmental impacts and feasible mitigation for those impacts. See CEQA Guidelines § 15002(a)(1) (listing as one of the "basic purposes" of CEQA to "[i]nform governmental decision makers and the public about the potential, significant environmental effects of proposed activities").

This letter is submitted along with comments prepared by: Silvia Secchi, Ph.D., Professor, Department of Geographical and Sustainability Sciences, University of Iowa, Attachment A ("Secchi Comments"); and Paul Rosenfeld, Ph.D., Principal Environmental Chemist, Soil Water Air Protection Enterprise ("SWAPE"), Attachment B.

I. The Proposed Amendments incentivize factory far expansion and the installation of anaerobic digesters.

The Proposed Amendments will greatly increase the incentive that already exists under the Low Carbon Fuel Standard ("LCFS") for factory farm expansion and digester installation.

290.2

This is evidenced in the stated Project objectives, which specify the following objectives:

- Increase credit prices by increasing the carbon intensity benchmarks (Objectives 1-4, Draft EIA at 13)
- Incentivize more digesters to achieve the Senate Bill 1383, Senate Bill 32, and Assembly Bill 1279 GHG reduction targets (Objective 5, Draft EIA at 13).

- Use the LCFS to build out and then transition biomethane infrastructure from supplying transportation fuels to supplying hydrogen fuels for stationary sources (Objective 5, Draft EIA at 13).

Therefore, CARB has designed the Proposed Amendments to increase carbon intensity targets, which in turn, will increase demand for credits and increase credit prices. Currently, biomethane accounts for approximately 20 percent of credits generated but only 1 percent of energy used for transportation.[2] The quantity and growth of biomethane credits in the LCFS has contributed to a glut of credits at low prices and diminished incentive for biogas investors to expand their investments.[3] The Proposed Amendments would increase the value of LCFS credits and incentivize investors to build
290.2 cont. more digesters and generate more credits. The Proposed Amendments incentivize fuel production practices that will, in fact, increase GHG emissions and result in significant environmental impacts.

The Proposed Amendments include three distinct changes to the LCFS that will increase the incentives factory farms have to expand their operations and install anaerobic digesters: (1) strengthening the carbon intensity benchmark, thereby increasing the price of credits for eligible fuel pathways, including electricity, natural gas, and hydrogen generated from factory farm manure methane emissions; (2) limiting biomethane pathways eligible for LCFS credits with deliverability requirements, which will also increase the price of credits for eligible fuel pathways; and (3) restricting new compressed natural gas and hydrogen fuel pathways that qualify for 35 years of avoided methane crediting to those that CARB certifies or that break ground by December 31, 2029.

By strengthening the carbon intensity benchmark from a 20% reduction in carbon intensity by 2030 to 30% by 2030 and establishing a new 90% carbon intensity reduction benchmark by 2045, CARB will increase demand for LCFS credits in the near-term, especially with the "step down" in 2025.[4] The intended and inevitable effect of this change will be to increase the demand of LCFS credits available for purchase, thereby increasing credit prices. Thus, those fuel pathways that qualify for credits after the amendments go into effect—including electricity, natural gas, and hydrogen derived from

---

[2] Aaron Smith, 2024.01.22 article https://asmith.ucdavis.edu/news/cow-poop-now-big-part-california-fuel-policy attached as Attachment C.
[3] Id.
[4] CARB Staff Report: Initial Statement of Reasons, at 22-26 (December 19, 2023) ("ISOR").

factory farm manure—will receive more money per credit sold. The Proposed Amendments will therefore incentivize factory farms to increase their herds to maximize manure methane production (credit generation). This proposed change will also provide incentives for the installation of digesters at factory farms, and thus result in GHG and air pollutant emissions.

Additionally, the amendments include new deliverability requirements that will limit the biomethane eligible for LCFS crediting to biomethane "carried through common carrier pipelines that physically flow within California or toward end use in California."[5] Currently, all factory farms across the nation can qualify for LCFS credits on the same basis as factory farms in California. As with the carbon intensity benchmark change, these deliverability requirements will further limit the supply of LCFS credits, thereby increasing the amount of money eligible fuel producers receive per credit. Also, by limiting eligibility to those factory farms that have a connection to California, these deliverability requirements will further incentivize factory farm expansion specifically in California along with the installation of digesters at livestock facilities in California.

290.2 cont.

Lastly, the Proposed Amendments draw a bright line between factory farm fuel pathways that are certified before, and after, January 1, 2030, with respect to avoided methane crediting.[6] If a factory farm fuel pathway is certified before January 1, 2030, that pathway is eligible to be renewed for up to three consecutive 10-year crediting periods. However, fuel pathways for bio-CNG, bio-LNG, and bio L-CNG from projects that break ground after December 31, 2029 can only generate avoided methane credits through December 31, 2040. Similarly, fuel pathways for hydrogen from projects that break ground after December 31, 2029 can only generate avoided methane credits through December 31, 2045. The Proposed Amendments therefore provide a significant incentive for factory farms to expand their herds and install digesters before December 31, 2029.

The Proposed Amendments' incentives to expand CAFO herds and install polluting anaerobic digesters by increasing the monetization of manure methane will have significant impacts on the environment which the Draft EIA fails to adequately analyze and fails to require feasible mitigation or project alternative, as described below.

---

[5] ISOR, at 30-31.
[6] ISOR, at 31.

II. The Draft EIA's Environmental Impacts analysis violates CEQA.

A. The Draft EIA fails to analyze the Proposed Amendments' environmental impacts.

1. Expansion of factory farm herds is a reasonable expected result in response to the Proposed Amendments.

290.3

CEQA requires lead agencies to analyze all reasonably foreseeable environmental impacts caused by a project they are proposing to approve. *Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 396-98; *Ebbets Pass Forest Watch v. Cal. Dept. of Forestry & Fire Protection* (2008) 43 Cal.4th 936, 954-55. A public agency can only omit analysis of its project's impact if it is "speculative." *Santa Rita Union School District v. City of Salinas* (2023) 94 Cal.App.5th 298, 334-36. An agency's conclusion that a particular environmental impact is too speculative to be adequately analyzed must be supported by substantial evidence. *Id* at 335. To support such a conclusion, the CEQA Guidelines require lead agencies to conduct a "thorough investigation" and "note its conclusion" that the impact is too speculative to be considered. 14 Cal. Code Regs. § 15145; *County of Butte v. Dept. of Water Resources* (2023) 90 Cal.App.5th 147, 161; *Citizens' Committee to Complete the Refuge v. City of Newark* (2021) 74 Cal.App.5th 460, 479.

The Draft EIA's analysis is "based on reasonably foreseeable compliance responses that are based on a set of reasonable assumptions" and purportedly "includes actions that could likely occur under a broad range of the potential scenarios."[7] As explained in Section I, *supra*, the Proposed Amendments include three distinct changes that increase factory farms' incentive to generate more LCFS-eligible fuel by expanding existing herds and installing digesters. The Draft EIA considers the installation of anaerobic digesters a reasonable compliance response because the Proposed Amendments would "incentivize the collection and use of biomethane gas from dairies."[8]

The same elements of the Proposed Amendments that incentivize collecting existing biomethane at factory farms also incentivize increasing the volume of biomethane at factory farms. This incentive to produce more methane necessarily includes expanding factory farm herds to generate more manure. However, the Draft EIA ignores this potential impact entirely. The Draft EIA fails to provide any evidence, let

---

[7] ISOR, at 39.
[8] Draft EIA, at 64.

alone substantial evidence, supporting its omission of factory farm expansion as a reasonable compliance response.

290.3 cont.

As explained in Dr. Secchi's comments, the analysis of Project-related impacts related to resulting factory farm expansion fails for two reasons. First, the "ISOR offers no monitoring data showing whether the LCFS has caused, or the proposed amendments will cause, herd expansions at dairies or hog facilities located in California or outside of California."[9] Without such data, the Draft EIA has no evidence to support an assumption that the use of digesters at factory farms results in a reduction of methane emissions overall.

Second, the evidence demonstrates that since the adoption of the low carbon fuel standard and Federal subsidy programs encouraging use of digesters, factory farms have expanded both inside and outside of California.[10] Dr. Secchi posits that, in reality, the incentives created by the Proposed Amendments are likely to result in significant expansion of factory farms that will, in turn, increase the amount of methane produced.[11] Recent deregulation of biodigesters in Iowa is correlated with dairy expansions in that state.[12] As explained above, by increasing the carbon intensity benchmark and the value of credits, the Proposed Amendments will incentivize increased expansion and concentration of dairy operations leading to increased adverse environmental impacts (as discussed further below). The aforementioned is a reasonably foreseeable compliance response that is not accounted for in the ISOR or the Draft EIA.

Recent data from the USDA Ag Census further demonstrates that during the period that CARB has implemented its avoided methane crediting policy (since the 2018 LCFS amendments), the number of milk cows at large, California dairies have increased while the number of milk cows at smaller dairies have decreased, showing that the California dairy herd is consolidating into larger dairies that produce and store sufficient quantities of manure to finance and generate revenues from captured methane. The data show that for dairies with 2,500 or more milk cows, the milk cow herd increased from 808,503 milk cows in 2017 to 1,025,716 milk cows in 2022, or an increase of 28.6 percent. In contrast, the data show that for dairies with less than 1,000 cows, the milk cow herd *decreased* from 303,746 milk cows in 2017 to 144,472 milk cows in 2022, or a

[9] Attachment A, Secchi Comments, at 1.
[10] Id. at 5 and 6.
[11] Id.
[12] Id. at 3.

290.3 cont.

decrease of 52.4 percent.[13] While correlation does not establish causation, the data strongly suggest that the LCFS has had a substantial effect on the increase in milk cows at the largest dairies which are most likely to install digesters and monetize their manure.[14]

2. The Draft EIA fails to adequately analyze nitrogen-based emissions from digesters that contribute to PM2.5 nonattainment and climate change.

290.4

Having failed to properly analyze the foreseeable expansion of factory farms as a result of the Project, the Draft EIA fails to analyze the Project's related impacts. It is well-established that "industrial dairies in the San Joaquin Valley are a major source of local air and water pollution, nuisance odors, groundwater overdraft, and greenhouse gas emissions."[15] Specifically, dairies are the largest source of volatile organic compounds, in the San Joaquin Valley. Oxides of nitrogen result from combustion of fuels, including biogas fuels from anaerobic digesters. Volatile organic compounds and NOx are precursors to ozone formation, which can cause a variety of respiratory illnesses, especially in children and for people who have asthma.[16] Factory farms and the resulting digestate are also a significant source of ammonia, which impacts nearby residents as a toxic gas and also reacts to form ammonium nitrate, a form of fine particulate matter for which the EPA has classified the valley as nonattainment with the federal health-based National Ambient Air Quality Standard.[17]

---

[13] The data also show that for dairies with more than 1,000 cows, the milk cow herd increased from 1,446,583 milk cows in 2017 to 1,543,730 milk cows in 2022, an increase of 6.9 percent.
[14] U.S. Department of Agriculture Census, attached as Attachment D.
[15] *See*, Briefing paper: Factory Farm Dairies, Biogas, and the Dangerous Path California is On, Leadership Counsel for Justice and Accountability, 2023, Attached as Attachment E.
[16] U.S. Environmental Protection Agency, "Health Effects of Ozone Pollution", attached as Attachment F and available at https://www.epa.gov/ground-level-ozone-pollution/health-effects-ozone-pollution#:~:text=Depending%20on%20the%20level%20of%20exposure%2C%20ozone%20can%3A,diseases%20such%20as%20asthma%2C%20emphysema%2C%20and%20chronic%20bronchitis.
[17] *See* 87 Fed. Reg. 60494 (Oct. 5, 2022) (proposed disapproval of plan to attain the 2012 annual PM2.5 standard), attached as Attachment G.

290.4 cont.

In addition, contaminated runoff can result in water pollution in both surface and ground water; the intensive water use required by factory farms results in overdraft of groundwater supplies; and caustic ammonia emissions can result in illness and odors. As discussed below, the Draft EIA's failure to analyze the impacts of the Proposed Amendments, both resulting in significant expansion of factory farms and due to increased use of digesters, implicates the EIA's analysis of all of the aforementioned environmental impacts. Even where the Draft EIA did purport to evaluate impacts, the analysis is perfunctory.

(a) Ammonia Emissions

290.5

Ammonia, a toxic, odorous gas, causes respiratory issues; irritation to the throat, lungs, and eyes; and lung damage if exposure to elevated ammonia levels is prolonged.[18] In addition to the health risks imposed by increased local emissions, ammonia also reacts with nitrogen oxides (e.g., NOx) in winter and contributes to the formation of ammonium nitrate, a fine particulate matter ("PM2.5").[19] In the United States, ammonia from agriculture accounts for the formation of almost one third of PM$_{2.5}$.[20] Exposure to PM 2.5 is linked to premature deaths in people with heart or lung disease, heart attacks, irregular heartbeat, aggravated asthma, decreased lung function and long-term lung conditions including cancer.[21] Yet, the Draft EIA's analysis of the Project's public health and safety impacts is cursory at best.

(b) Greenhouse Gases

290.6

The Draft EIA analysis omits a full accounting of greenhouse gas emissions resulting from both a foreseeable expansion of factory farms and increased use of digesters.[22] For example, as the Rosenfeld Comments explain, during biogas combustion in the anaerobic digestion process, ammonia is oxidized into nitrous oxides. Furthermore,

[22] Attachment A, Secchi Comments, at 6.

290.6 cont. digestate solids emit significant nitrous oxide emissions that negate methane captured by the digester. According to the EPA, nitrous oxide ("N2O") has a Global Warming Potential that is 273 times that of carbon dioxide ("CO2") for a 100-year timescale.[23] Therefore, N2O emitted today remains in the atmosphere for more than 100 years, on average.[24] Yet, the Draft EIA omits any evaluation impacts from Project-related increases of N2O.

In another example, NOx emissions react with volatile organic compounds in the presence of sunlight to form ozone, which also contributes to climate change. Ozone (O3) is the third most important anthropogenic greenhouse gas after carbon dioxide (CO2) and methane.[25] NOx also reacts with ammonia to form ammonium nitrate, a form of PM2.5. The San Joaquin Valley of California, where most factory farms and biodigesters are located, is a nonattainment area for both ozone and PM2.5National Ambient Air Quality Standards. However, the Draft EIA provides only a cursory—and internally inconsistent—discussion of the potential impacts related to ozone and PM2.5 formation. On the one hand, the Draft EIA states the Proposed Amendments "*could* result in an overall decrease in long-term operational NOx and PM2.5 emissions…in all state-designated ozone non-attainment areas from 2024 through 2046," (emphasis added) with a corresponding reduction in health impacts.[26] But the Draft EIA then pivots to conclude that long-term impacts from NOx and PM 2.5 emissions "could be potentially significant and unavoidable."[27]

The Draft EIA's conclusion that the Proposed Amendments could reduce NOx and PM2.5 emissions fails to account for emissions resulting both from the increased use of digesters and the expansion of factory farms. To the extent the Draft EIA makes any attempt to acknowledge the potentially significant impacts of increased NOx and PM2.5, it does not provide any of the information required by CEQA to explain the extent and severity of these impacts. The Draft EIA's failure to provide meaningful information about the significance of these impacts violates CEQA. *Cleveland Nat'l Forest Foundation v. San Diego Assn. of Governments* (2017) 3 Cal.5th 497, 514 ("an EIR's designation of a particular adverse environmental effect as 'significant' does not excuse

290.6 cont. the EIR's failure to reasonably describe the nature and magnitude of the adverse effect"); *Berkeley Keep Jets Over the Bay Com. v. Board of Port Cmrs.* (2001) 91 Cal.App.4th 1344, 1371 ("simply labeling the effect 'significant' without accompanying analysis of the project's impacts … is inadequate to meet the environmental assessment requirements of CEQA").

3. The Draft EIA Fails to Adequately Analyze NOx emissions from Flaring.

290.7 The Draft EIA refers to the air quality analysis in the Standard Regulatory Impact Assessment ("SRIA") as the basis for its estimates of criteria pollutants.[28] In the SRIA, CARB estimated emissions from flaring at digesters. The Draft EIA states that "[S]taff assumed that about 10% of methane produced is flared. Hence, flaring is the only source of local emissions used in estimating emissions from dairy biomethane."[29] Ammonia in flared biogas causes increased NOx emissions.[30] However, the SRIA only used air district emission factors for flares.[31] Thus, the EIA fails to adequately analyze NOx emissions from flaring biogas. A revised EIA should recalculate digester flare emissions using flared biogas.

4. The Draft EIA Fails to Adequately Analyze NOx emissions from Biomethane Electric Fuel Pathways.

290.8 In its evaluation of Project-impacts related to biomethane electric vehicle fuel pathways, the Draft EIA indicates that "[T]he LCFS modeling assumes use of fuel cells to generate this electricity, which do not rely on combustion."[32] Thus, staff calculate near zero NOx from electricity production of biomethane using an emission factor of 0.00085 tons/GWh.[33] However, this assumption underlying the analysis is questionable for multiple reasons. First, to date, CARB has certified only one biomethane electric vehicle fuel pathway that relies on Bloom fuel cells at a dairy to produce electricity, and that is at

[28] Draft EIA, at 58.

[33] Id.

Bar 20, one of the largest dairies in California. By contrast, CARB has certified 19 biomethane electric vehicle fuel pathways that rely on internal combustion engines[34] .

Second, Bloom fuel cells are more expensive to purchase and maintain than internal combustion engines, and the San Joaquin Valley Unified Air Pollution Control District has declined to find that fuel cells are cost-effective and thus Best Available Control Technology ("BACT"). Instead, the District has issued Authority to Construct Permits and found that internal combustion engines represented BACT. Therefore, CARB lacks substantial evidence to support its unfounded assumption Bloom fuel cells will be used for electric vehicle fuel pathways. And while Bar 20 has permits for and operates fuel cells, there is no record on the Air District public notice log of *any* BACT determination for fuel cells at Bar 20.[35]

290.8 cont.

Furthermore, the most recent internal combustion engine Authority To Construct Permit from the San Joaquin Valley Air District found that fuel cells were not cost-effective and not BACT. Instead, the Air District required internal combustion engines as BACT.[36] This approach is inconsistent – on the one hand, the Air District does not consider fuel cells as BACTs or cost effective and does not require fuel cells as BACT; on the other hand, CARB's analysis of impacts from digester projects that generate electric vehicle fuel contends that all such fuel pathways will rely on fuel cells to emit near-zero NOx.

NOx emissions from digester-related internal combustion engine used for electric vehicle fuel pathways are significant. For example, the Lakeview Dairy Biogas project in Kern County uses two internal combustion engines to produce over 1,000 kW of electricity on-site.[37] And this project, as permitted by the Air District with required internal combustion engines, still emits 4.58 tons/year of NOx, 1.98 tons/year of PM2.5,

Air Res. Bd., LCFS Tier 2 Pathway App. B0104 (certified TBD), attached as Attachment O and available at https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/fuelpathways/comments/tier2/b0104_summary.pdf.

290.8 cont. and 3.18 tons/year of VOC *after* the imposition of BACTs as required by the State Implementation Plan.[38] Compared to a natural gas combined cycle power plant in Avenal, also permitted by the Air District, the Lakeview digester project produces much higher levels of NOx, sulfur oxides (SOx), and VOC emissions per unit of electricity generated.[39] However, unlike the natural gas plant, Lakeview Dairy Biogas is not required to purchase emission reduction credits for the air pollution emitted. This facility, and others like it with internal combustion engines, emit significant levels of NOx even after Clean Air Act-required controls.[40] Therefore, the Draft EIA wrongfully omitted analysis NOx emissions from these facilities and fuel pathways.[41]

In summary, given that (a) the Proposed Amendments increase carbon intensity benchmarks, and thus credit prices, and will incentivize more pathways for electricity from internal combustion engines, (b) CARB does not require fuel cells as mitigation, and (c) the San Joaquin Valley Unified Air Pollution Control District does not consider fuel cells as BACT, it is reasonably foreseeable that more digesters with IC engines will apply for such pathway certifications. For these reasons, the Draft EIA must be revised to correct this error and to evaluate NOx impacts from biomethane electric vehicle fuel pathways that rely on IC engines.

5. The Draft EIA Fails to Adequately Analyze NOx emissions after 2039.

290.9 The Draft EIA fails to analyze NOx emissions from biomethane fuel pathways after 2039, despite authorizing crediting for biomethane fuel pathways well beyond 2039. The Draft EIA's PM2.5 and NOx emissions analysis explicitly relied on the Standardized Regulatory Impact Assessment ("SRIA"), including Tables 47-59.[42] Table 47 of the SRIA assumes no hydrogen or electricity will be produced from dairy biomethane after 2039.[43] However, as discussed in Section I, the Proposed Amendments explicitly

290.9 cont. authorize CARB to certify electricity and hydrogen fuel pathways well beyond 2039. The Draft EIA's analysis of NOx emissions is grounded on an inaccurate assumption. The Draft EIA must evaluate the impacts of NOx emissions over the time period during which these emissions will occur. 14 Cal. Code Regs. § 15126 ("[a]ll phases of a project must be considered when evaluating its impact on the environment"); *Make UC a Good Neighbor v. Regents of University of California* (2023) 88 Cal.App.5th 656, 667; *In re Bay-Delta etc.* (2008) 43 Cal.4th 1143, 1169.

6. The Draft EIA fails to adequately analyze Project-related ammonia emissions associated with digestate.

290.10 Aside from omitting analysis of the impacts resulting from factory farm expansion and use of anaerobic digesters described above, the Draft EIA presents an incomplete analysis of the project's ammonia impacts because it fails to evaluate the impacts from production and application of substantial increases of anaerobic digestate.[44] Apart from the size of the herd, the production and application of digestate to agriculture land is much more polluting and more hazardous to public health compared to raw manure.[45] CEQA requires an analysis of these impacts.

The Draft EIA's conclusion that the Project may have significant air quality impacts—without consideration of the extent and severity of those impacts—cannot cure this deficiency. Merely stating that an impact will occur is insufficient; an EIR must also provide "information about how adverse the adverse impact will be." *Cleveland Nat'l Forest Foundation*, 3 Cal.5th at 514; *Berkeley Keep Jets Over the Bay Com.*, 91 Cal.App.4th at 1371. This information, of course, must be accurate and consist of more than mere conclusions or speculation. *Id.* The Draft EIA's analysis of air quality impacts fails to fulfill this mandate in several instances.

(a) Air pollution

290.11 Anaerobic digestate results in higher emissions in part because anaerobic digestion decomposes the waste into smaller molecules, which allows it to more easily volatilize into the atmosphere.[46] In this way, digestate results in significant releases of higher

---

[44] Draft EIA at 56-62 (concludes impacts to air quality are significant); at 64-65 (concludes impacts from odor are not significant); Attachment B, Rosenfeld comments, at 2 and 3.

[46] Attachment B, Rosenfeld comments, at 3.

amounts of ammonia, a toxic gas, and NOx emissions than unprocessed manure.[47] The Draft EIA concludes that long-term operational air quality impacts related to PM2.5 and NOx would be significant and unavoidable.[48] We do not disagree that the Project's emissions would be significant. However, the DEIR fails to disclose the extent and
290.11 cont. severity of this impact.[49] A revised analysis must provide more details about the impacts and must account for increased application of digestate on agricultural land. *Cleveland Nat'l Forest Foundation*, 3 Cal.5th at 514; *Berkeley Keep Jets Over the Bay Com.*, 91 Cal.App.4th at 1371.

Furthermore, the Draft EIA's conclusion that odor impacts from ammonia emissions would not be significant is unsupported. As explained in the Rosenfeld Comments, ammonia emits a strong odor that is easily detectable at low concentrations and contributes to irritation such as immediate burning of the nose and respiratory tract.[50] In addition, anaerobic digestion significantly increases the amount of ammonia emissions compared to a dairy without an anaerobic digester.[51]

As discussed above, ammonia also contributes to the formation of $PM_{2.5}$ (e.g., formation of ammonium nitrate), exposure to which is linked to a variety of serious health problems).[52] CARB's own ammonia data show that ammonia contributes to PM2.5 formation.[53] Therefore, CARB must include a full evaluation of ammonia emissions.

(b) Public Health and Safety

Health and safety effects, including adverse health impacts from air pollutants,
290.12 may constitute significant environmental impacts for the purposes of CEQA. See, e.g., *Sierra Club v. County of Fresno* (2018) 6 Cal.5th 502, 517-22; *Bakersfield Citizens for*

[53] 2023 CARB Ammonia Demonstration re 1997 PM2.5 plan standard SJV at 3, attached as Attachment S.

Local Control v. City of Bakersfield (2004) 124 Cal.App.4th 1184,1219-21. 14 CCR § 15126.2(a). Here, as discussed above, in the anaerobic digestion process substantial amounts of ammonia are produced as a byproduct.

290.12 cont.

In addition to the health risks imposed by increased local emissions, emissions and impacts on nearby communities, ammonia also contributes to the formation of $PM_{2.5}$.[54] In the United States, ammonia from agriculture accounts for the formation of almost one third of $PM_{2.5}$.[55] Exposure to PM 2.5 is linked to premature deaths in people with heart or lung disease, heart attacks, irregular heartbeat, aggravated asthma, decreased lung function and long-term lung conditions including cancer.[56] Yet, the Draft EIA's analysis of the Project's public health and safety impacts is cursory.[57] While the Draft EIA discloses that an increase in emissions of criteria pollutants associated with production of biofuels is possible, it falls short of actually evaluating the potential health impacts of these emissions.[58] Instead, once again the Draft EIA concludes that impacts would be significant, but then fails to describe the severity of those impacts.

Harmful emissions from expanded use of anaerobic digesters disproportionately affect communities in close proximity to dairies, which are often comprised of lower-income residents. Lower-income residents are often more vulnerable to the adverse effects of these emissions due to various factors, such as lack of resources, inadequate infrastructure, and the concentration of anaerobic digester facilities near these populations.

(c) Impacts Outside of California

290.13

The Draft EIA fails to analyze the Proposed Amendments' impacts outside of California. CEQA requires public agencies to analyze the potentially significant impacts of a proposed project that may occur in "the area which will be affected by [the] proposed project." 14 Cal. Code. Regs. § 15360; Public. Res. Code § 21060.5. CARB itself acknowledged its obligation to analyze out-of-state impacts in conducting its CEQA

290.13 cont.

review for the Renewable Electricity Standard in 2010.[59] Factory farms across the nation are eligible for LCFS credits, and are thus incentivized by the Proposed Amendments to install anaerobic digesters and expand existing herds, just as in-state factory farms are. The Proposed Amendments will therefore have adverse environmental impacts out-of-state. CARB's refusal to analyze such impacts is clear legal error.

7. The Draft EIA fails to adequately analyze Project-related discharges to groundwater associated with digestate.

The Draft EIA's analysis of increased digestate on groundwater is equally flawed. As explained in the Rosenfeld Comments, anaerobic digestion breaks down waste into a digestate of smaller molecules that makes digestate more susceptible to leaching into the groundwater.[60] Anaerobic digestion also leads to higher concentrations of ammonia in digestate, which can subsequently convert to nitrate.[61]

290.14

"[N]itrate pollution leading to groundwater contamination is much more likely to occur with anaerobically digested digestate, as the ammonia is more readily available for conversion into nitrate, which can then leach into groundwater."[62] Nitrate contamination in drinking water and food can lead to severe illness in infants, such as the onset of blue baby syndrome, also known as methemoglobinemia.[63] Yet, the Draft EIA fails to include any analysis of these potential impacts.

Although the Draft EIA concludes that the Project's long-term operational impacts to water quality are significant and unavoidable, the document lacks a thorough analysis of these impacts. As the Rosenfeld Comments explain, increased amounts of digestate have the potential to result in groundwater nitrate contamination, excessive accumulation of soil phosphorus, and eutrophication of surface waters from anaerobic digesters.[64] These impacts to water quality and public health must be evaluated in a revised EIA.

---
