# Concern

---

- **Step on a bathroom scale. Do you have enough cash to buy coffee?**
  - **If you have a pound of money, probably yes!**
  - **If you only have a few \$1's, you can't tell!**
- **Our ability to measure small emissions differences and the desire to test low concentration ranges are not compatible.**
- **The next chart assumes a  $\pm 1\%$  error band and illustrates we either have to:**
  - **Measure more precisely, Or**
  - **Use greater concentration changes**

# $\pm 1\%$ Error Band Can Create Statistical Insignificance

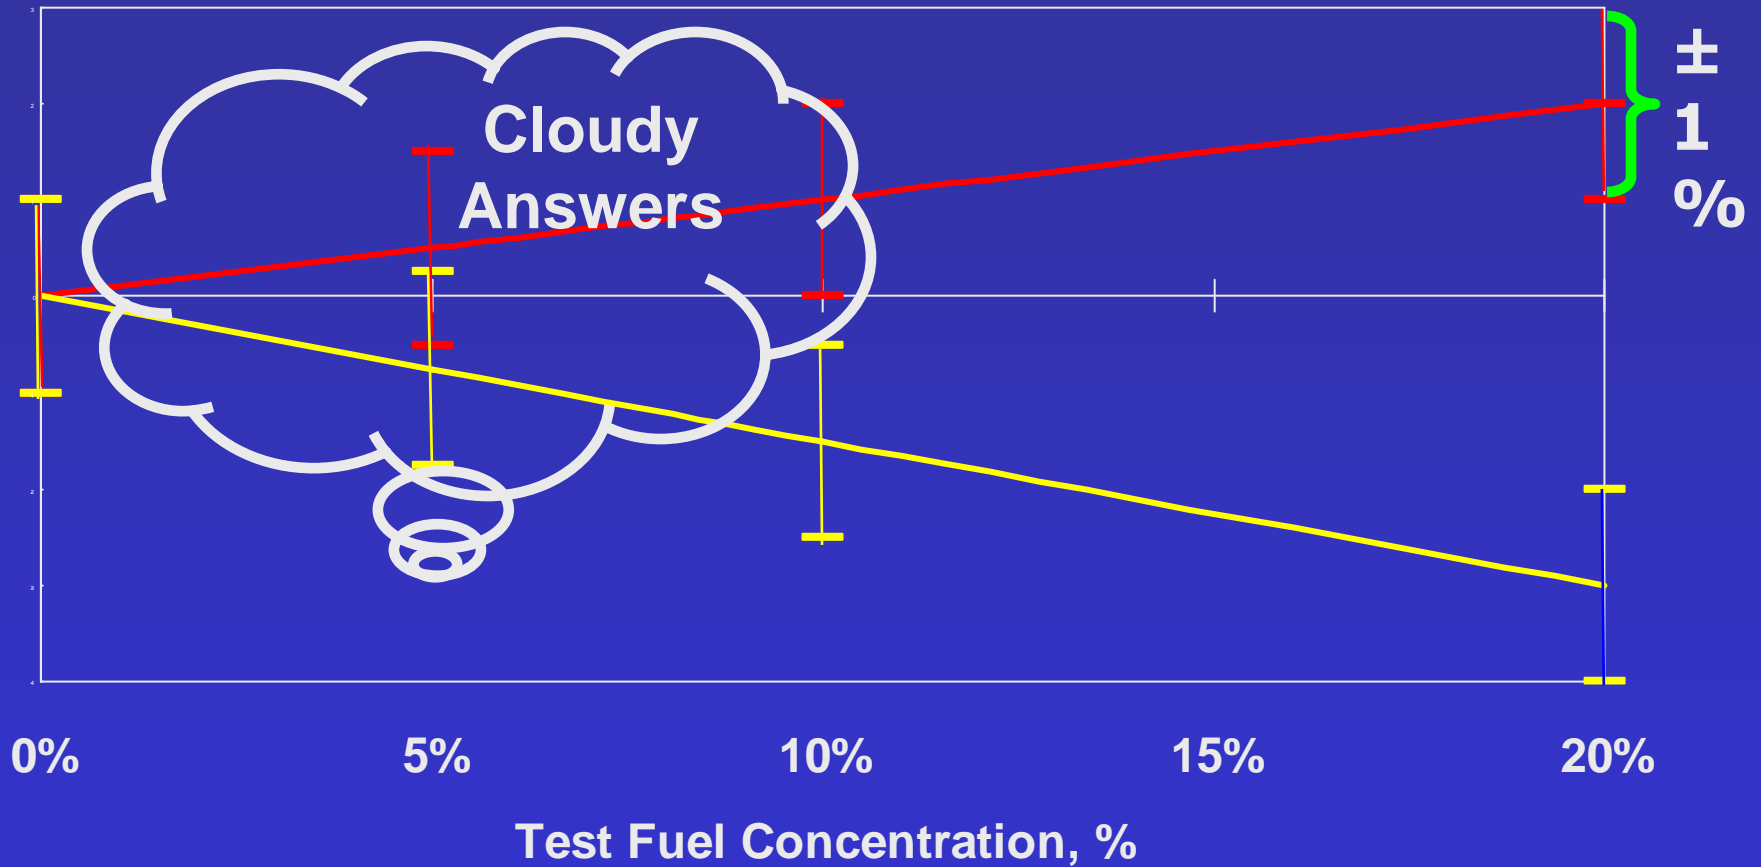

# Remember

---

- **We are measuring differences between two very small numbers.**
- **To illustrate, I over simplify and assume one pure component increases the difference by 10% and the other decreases it by 15% and that the impact is linear with concentration**
- **Measuring that difference to  $\pm 1\%$  is outstanding.**
- **For large differences, no problem.**
- **But, with small differences the error bands overlap**
  - **Overlapping zero creates statistical insignificance**
  - **Overlapping product responses means no statistically significant difference in responses**
- **Now lets look at low concentration range**

# **$\pm 1\%$ Error Band Creates Statistical Insignificance**

# Observations

---

- **At 5% concentration the +10% change product with a  $\pm 1\%$  error band yields a statistically insignificant conclusion.**
- **The -15% change product with a  $\pm 1\%$  error band also yields a statistically insignificant conclusion at 5% concentration.**
- **What is even worse is that the error bands overlap each other meaning the experiment showed no statistically significant differences between the products at 5% concentration.**
- **So how much change do we need to get statistical significance at low concentrations?**

# Minimum Observed Pure Component Change Required for Statistical Significance

Error Band	$\pm 1\%$	$\pm 2\%$	$\pm 3\%$
5% Concentration	>20	>40	>60
20% Concentration	>5	>10	>15
50% Concentration	>2	>4	>6

# Implications

- **Obviously we must minimize the error band.**
- **Unless the biofuels cause very large changes the 5% concentration tests are a waste of money & opportunity.**
- **Create big question: What do we do with statistically insignificant answers at low concentrations when we have statistically significant results at high concentrations?**
  - **Do we increase the number of runs?**
  - **Do we discard the data?**
  - **Do we allege no impact at low concentrations?**
  - **Do we use the trend line between significant findings and zero? Or**
  - **Do we design the experiment to reduce the probability of getting statistically insignificant results?**
- **Now lets estimate how much change we can expect.**

# Begin by Estimating the Properties of the Blends

	<b>CARB Base Fuel</b>	<b>5%</b>	<b>10%</b>	<b>20%</b>	<b>50%</b>	<b>Pure Product</b>
<b>Aromatics vol%</b>	<b>20</b>	<b>19</b>	<b>18</b>	<b>16</b>	<b>10</b>	<b>0</b>
<b>Sulfur,ppm</b>	<b>5</b>	<b>5</b>	<b>5</b>	<b>4</b>	<b>3</b>	<b>0</b>
<b>Alkanes Cetane</b>	<b>53</b>	<b>55</b>	<b>57</b>	<b>60.9</b>	<b>72.8</b>	<b>92.5</b>
<b>Esters Cetane</b>	<b>53</b>	<b>53.1</b>	<b>53.2</b>	<b>53.4</b>	<b>54</b>	<b>55</b>
<b>Alkanes SG</b>	<b>0.85</b>	<b>0.85</b>	<b>0.84</b>	<b>0.84</b>	<b>0.82</b>	<b>0.78</b>
<b>Esters SG</b>	<b>0.85</b>	<b>0.85</b>	<b>0.85</b>	<b>0.86</b>	<b>0.87</b>	<b>0.88</b>
<b>Alkanes T50</b>	<b>505</b>	<b>510</b>	<b>514</b>	<b>523</b>	<b>538</b>	<b>552</b>
<b>Esters T50</b>	<b>505</b>	<b>511</b>	<b>519</b>	<b>529</b>	<b>620</b>	<b>649</b>

# **Relative Impact on Blend Properties**

- **These properties are inputs to the Texas Commission on Environmental Quality's NOx predicting model.**
- **Alkanes and Esters have the same impact on sulfur and aromatics concentration.**
- **Esters have little impact on cetane while alkanes increase cetane significantly.**
- **Esters and Alkanes have opposite impacts on specific gravity.**
- **Esters raise T50 more than Alkanes do.**

# **TCEQ Unified Model**

---

- **The NOx prediction model was Down loaded from TCEQ's web site.**
- **It specifically does not apply to ester blends but it is OK for this task.**
- **All we want to do is see what the diesel property changes imply for NOx emissions.**

# In TCEQ Unified Model NO<sub>x</sub> Decreases When:

- Cetane increases
- T50 increases
- Aromatics decrease
- Specific gravity decreases
- Alkane impact is: + + + +
- Ester impact is: 0 + + -
- Also, model not certified for esters

# Estimated % NOx Reduction from Base

	5%	10%	20%	50%	Pure Product (1)
<b>Alkanes</b>	<b>-0.9</b>	<b>-3.1</b>	<b>-5.0</b>	<b>-12.2</b>	<b>-22.6</b>
<b>Esters (2)</b>	<b>-0.5</b>	<b>-0.7</b>	<b>-1.3</b>	<b>-4.6</b>	<b>-6.4</b>

(1) Extrapolated beyond model range

(2) Model not certified for esters

**Bottom line: It will be difficult if not impossible to get a statistically significant NOx finding at 5% concentration.**

# **Recommendations**

- **Run tests at 20, 50 & 100% concentrations before running low concentration blends.**
  - **Experience should improve our precision**
  - **We will know if the low-C runs are justified**
- **Run low concentration tests only if error bands and measured differences justify.**
- **I have recommended:**
  - **Neste supply the renewable diesel test fuel.**
  - **Fund an additional concentration level for the renewable diesel alkanes.**
  - **That the test matrix be changed to include R20, R50 and R100 runs on the older engine.**

# Thank you

---

- **If we have time, I will take some questions now.**
- **But, if you have more later, here are my contact data:**
