Laboratory Report No. 86-5
September 1987

DISCLAIMER

The statements and conclusions in this report are those of the contractor and not necessarily those of the California Air Resources Board. The mention of commercial products, their source, or their use in connection with material reported herein, is not to be construed as either an actual or implied endorsement of such products.

ACKNOWLEDGEMENTS

A number of individuals contributed to sample collection, analysis, report preparation, and review over the course of the monitoring effort. We especially wish to thank and acknowledge the invaluable support and analytical assistance provided throughout the study by N.M. Morgan, Department of Fish and Game (DFG) chief chemist. Appreciation is also extended to DFG staff R.J. Hansen, S.J. Baumgartner, W.T. Castle, D. Crane, W. Fiori, H.R. Fransen, T.S. Lew, and J.M. Polisini for time spent on this project. California Air Resources Board (CARB) staff member W. Walker provided many helpful discussions and encouragement as well as review of the draft report. J.R. Holmes, F. DiGenova, P.K. Amar, K.A. Tonnessen, C. Robertson (CARB), J.M. Melack, and J.O. Sickman (U.C. Santa Barbara) also provided assistance with various phases of the investigation.

This report was submitted in fulfillment of Contract No. A5-178-32 "Statewide Survey of Aquatic Ecosystem Chemistry" by the California Department of Fish and Game under the sponsorship of the California Air Resources Board.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

INTRODUCTION

California has approximately 5,000 lakes and 25,000 miles of rivers and streams. Many are located in granite basins with small watershed areas, possess thin watershed soils, and have low alkalinity waters, features which often characterize areas sensitive to acid deposition.

Fifty waters throughout the State (Figure 1, Appendix A) were sampled to (i) survey the water chemistry of selected California lakes and streams, (ii) determine the vulnerability of these waters to acidification, (iii) examine the seasonal variability of water chemistry parameters, (iv) provide a background database against which future measurements can be compared, and (v) identify geographical regions sensitive to acid deposition.

The first year of the 2 year study was completed in December 1985 (M^{c}Cleneghan et al. 1985). It was concluded that surface waters in certain regions of California demonstrated low alkalinity, low ionic strength, and low conductivity. Water with these characteristics are generally accepted as being very sensitive to acid deposition and susceptible to acidification because of their inability to buffer acidic inputs.

METHODS AND MATERIALS

Sampling Locations

Selected lakes and streams were sampled twice, once during spring run-off and again in late summer or fall, 1986. Major mountain ranges scattered throughout the State were selected based on:

i) suspected sensitivity to acidification
ii) geological characteristics
iii) elevation
iv) accessibility
v) lack of extraneous water quality influences
vi) presence or absence of fish or other aquatic organisms.

Sample Collection

All tubing, filters, and storage bottles were chemically cleaned prior to collection (Appendix B). Water samples were collected near the lake outlet using a battery powered Geotech peristaltic pump. Tubing extended from the pump along a floating pvc boom to 4.5 m from the shore and 0.5 m below the surface. Water was pumped through the tubing for approximately 5 minutes before sample collection in linear polyethylene bottles.

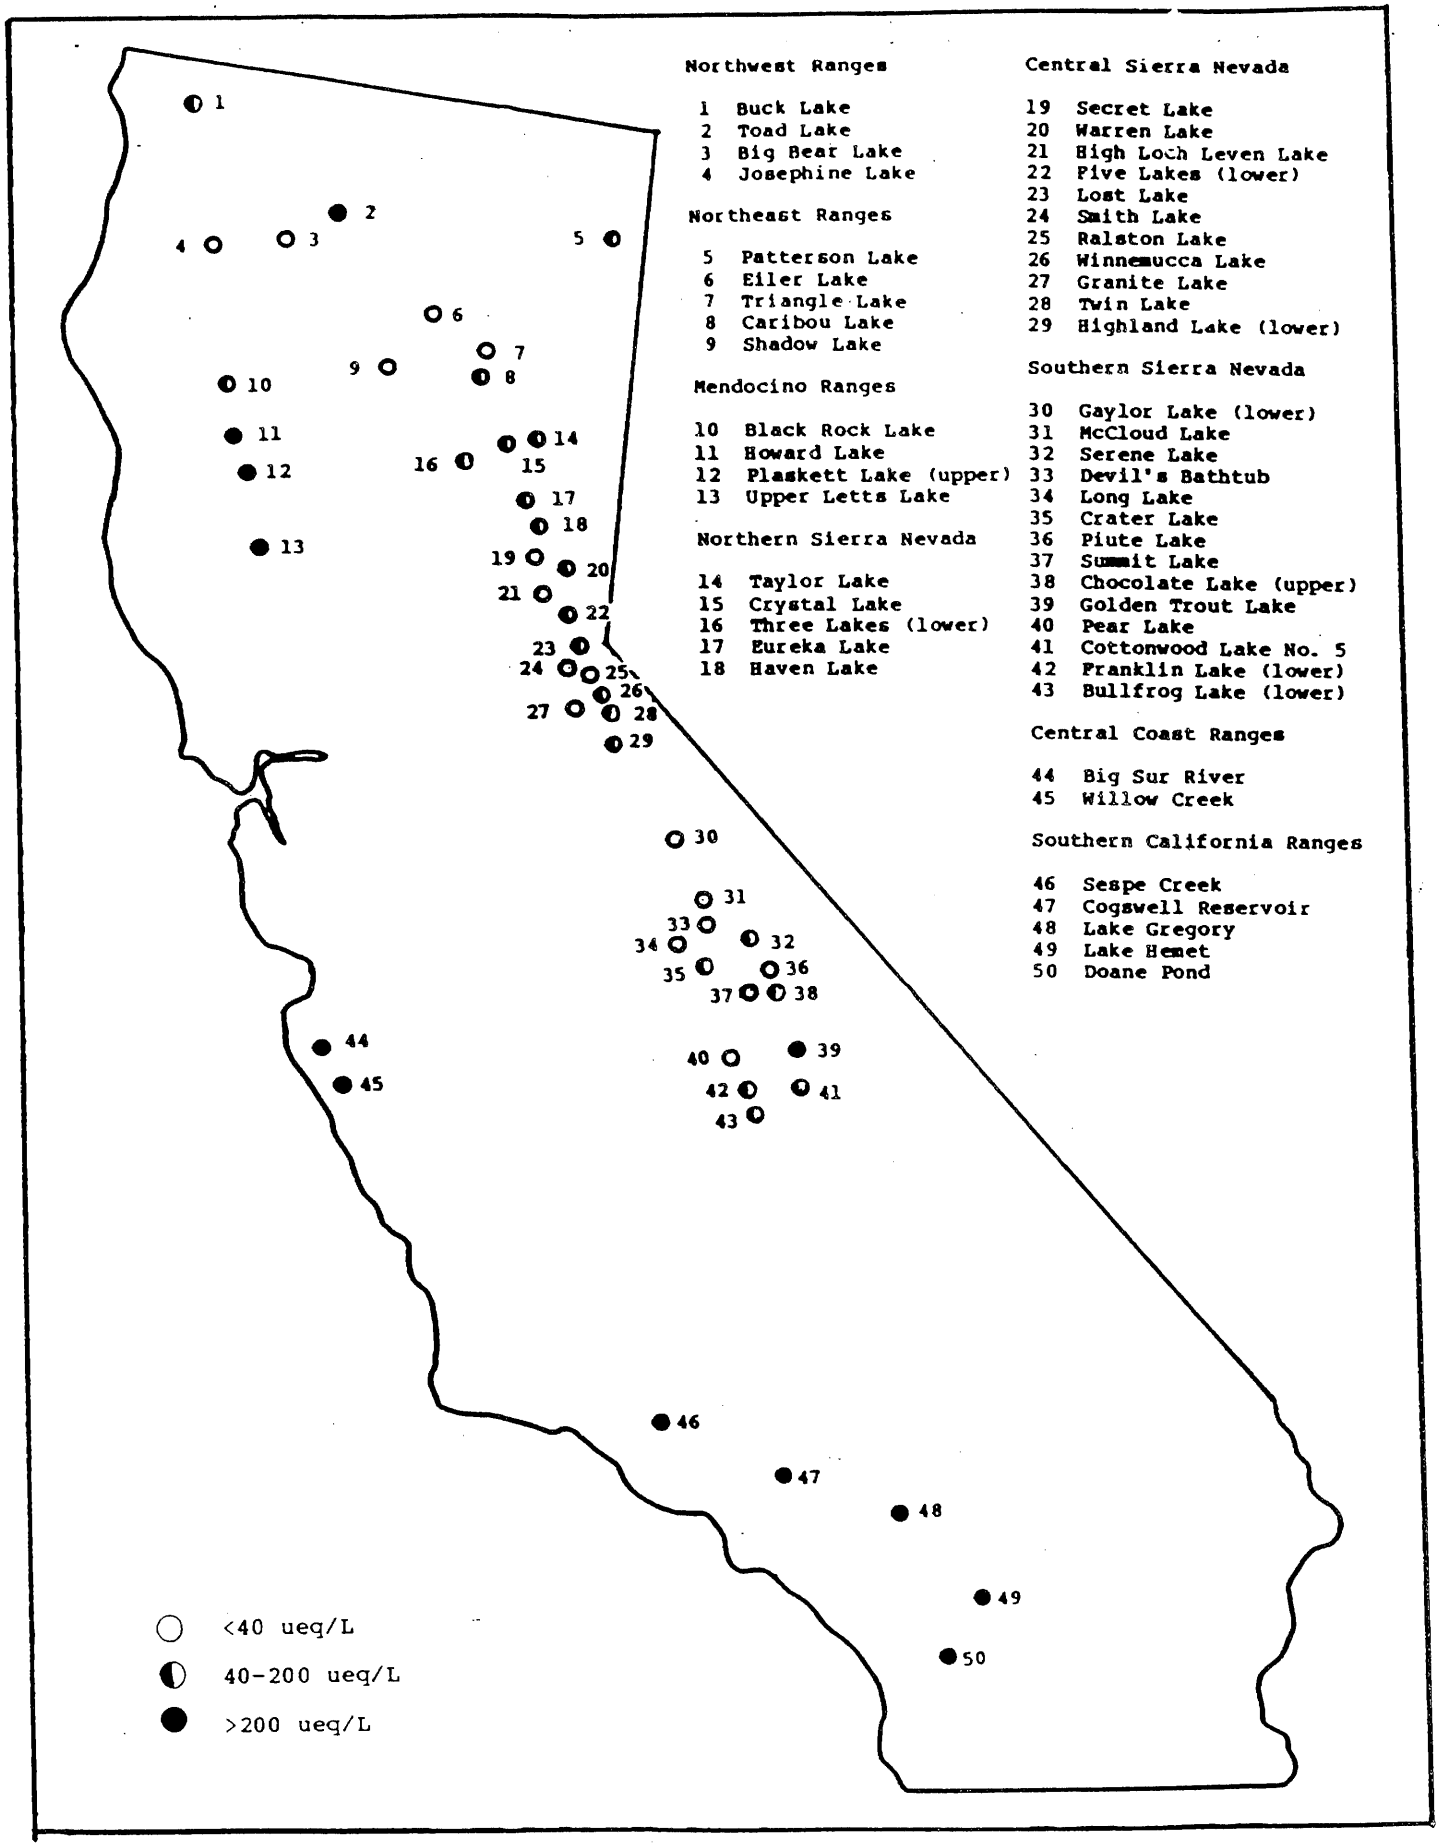

Figure 1. Station Locations; Statewide Survey of Aquatic Ecosystem Chemistry, 1986.

Water samples collected for metal (total and dissolved) and phosphate analyses were preserved shortly after collection with 0.25 ml 6N nitric acid per 60 ml of sample and 0.2 ml of concentrated (36N) hydrochloric acid per 125 ml of sample, respectively. Water samples for anions, cations, and nitrates were not fixed immediately but were analyzed within 30 days, the time specified by the U.S. Environmental Protection Agency (U.S. EPA), (Hillman et al. 1984).

On-Site Analyses

Three parameters were analyzed at the sampling site:

i) pH
ii) temperature
iii) conductivity

Prior to July 30, 1986, pH and temperature were measured using a temperature compensating Beckman 21 pH meter with a Beckman combination electrode (Star series) and temperature probe immersed in a continuous flowing sample. Most lakes sampled were located at relatively high elevations. Water temperature below 5°C and air temperature below 10°C were common. Typically these waters demonstrated very low conductivity. The combination of harsh environment and dilute waters caused instruments to require very long periods for reading stabilization; there was even occasional electrode failure. Galloway and Likens (1979) and Boyle et al. (1986) encountered similar problems of accurately measuring low ionic strength precipitation. Therefore, a revised procedure for measuring pH was adopted for the fall sampling period (Appendix C).

During the fall sampling period, pH and temperature were measured using two temperature compensating Beckman model 21 pH meters. One meter was equipped with an Orion combination electrode and the other meter with a Beckman combination electrode; both used the Beckman temperature probe. In addition, a third pH measurement was obtained using the Hach Models 17D and 17H colormetric kits. These simple tools provided quick and easy methods of determining the proper value range when discrepencies between pH meter readings occurred.

Conductivity measurements were obtained using the Beckman-Altex conductivity bridge model RC-16C with a 0.1 cm cell. Readings were temperature compensated to 25°C in accordance with American Public Health Association (APHA) 1985.

A 250 ml carboy was filled with unfiltered lake water for later determination of alkalinity. All alkalinity samples were analyzed within 12 hours except for Bullfrog and Franklin lakes which were analyzed within 24 hours. Alkalinity was determined using the potentiometric method with Gran plot as described by Hillman et al. 1984 (Appendix C).

Laboratory Analyses

Laboratory analyses for anions, cations, and trace elements were determined using various instruments and techniques (Appendix C). Sample preparations and analyses were performed according to instrument manufacturer's instruction and APHA (1985) unless otherwise noted (Appendix C). Tannin-like dissolved organic compounds and silica were two additional parameters analyzed during the 1986 sampling season. Tannins were analyzed because these may contribute to pH decrease. Silica was examined because concentrations in the water indicate the extent of chemical weathering in the bedrock of the surrounding watershed (Driscoll 1980).

Quality Assurance

A number of precautions were taken to ensure the validity of reported data. Quality assurance measures tested the precision and accuracy of instruments, equipment, analytical methods, and techniques of laboratory personnel techniques.

Intralaboratory Analyses

All sample collection bottles, filters, and filter housings were chemically cleaned (Appendix B) and tested for the presence of each measured parameter prior to use for sample collection. Any bottles, filters, or housings found to be contaminated were re-cleaned and re-tested.

Interlaboratory Analyses

Interlaboratory analyses were performed on U.S. EPA water samples (Appendix D). All parameters were within acceptable limits. The EPA water samples analyzed for quality control were more concentrated than water samples collected from the field. As a result, the EPA samples were diluted to concentrations which simulated typical alpine lake water. This ensured field samples and EPA samples had similar concentration ranges and were analyzed by similar laboratory and instrumentation conditions.

Replicate Analyses and Field Duplicates

Replicate analyses of each parameter analyzed in the laboratory were performed on approximately 10% of all samples. Duplicate field samples were collected at 10% of the stations. Results of replicate and duplicate analyses are reported (Appendix D).

Major Ion and Conductivity Balances

The ion balance for 96% of both spring and fall sampling stations were within guidelines for anion-cation balance (Appendix D) set by the U.S. EPA (Hillman et al. 1984). For purposes of the balance calculations, a "less than" value was equal to zero (even though the actual value was probably greater than zero but less than the detection limit). This calculating procedure may account for those stations where the anion-cation balance value lies outside the U.S. EPA guidelines. Instrument variation and sensitivity may also contribute to error, causing summed measurements to lie outside the guidelines.

The conductivity balance for 97% of the spring and fall stations (Appendix D) were within the U.S. EPA guidelines (Hillman et al. 1984. Instrument variation and sensitivity may account for those measurements which lie outside the guidelines.

For both the percent ion difference and the percent conductance difference, the median percent difference was within 0±5%, as specified by the U.S. EPA (Hillman et al. 1984). Consequently, measurement bias is not indicated.

DATA REPORT

The intent of the 1986 survey is to report the chemical characteristics of selected aquatic ecosystems in California; no interpretation of these results is made.

The results of field and laboratory analyses are presented by mountain range and season (Tables 1, 2, 3, 4, 5, and 6); results presented in alternate units are also reported (Appendix E). Means and ranges of measurements for the major water quality parameters-- pH, alkalinity, conductivity, calcium, and magnesium-- are summarized (Table 7). The pH values measured during the fall using the modified technique described in the Materials and Methods section are summarized (Table 8). Water quality parameters measured during the 1985 sampling season are included for comparison (Appendix E).

Several instances of trace element contamination of samples occurred; these were apparent because dissolved concentrations exceeded total concentrations (Table 3 and 6). All filters and sample containers were chemically cleaned and tested prior to field use. Contamination most likely occurred during field collection under adverse conditions (wind, rain, or snow). However, in those instances where dissolved trace element concentrations are only slightly greater than total trace element concentrations, the cause is most likely due to instrument variability and does not necessarily indicate sample contamination.

The vulnerability of California's pristine aquatic ecosystems to damage from acid deposition is cause for concern. However, neither the magnitude of the threat nor the extent of natural resources at risk are well defined. These circumstances justify the need for a comprehensive, systematic survey of water quality conditions in California lakes to clarify the acidification process, its progress, and to determine the existing or potential threat to the State's aquatic resources and habitats.

APPENDIX B

CLEANING SUMMARY AND PROCEDURES

APPENDIX B. Cleaning summary and procedures.

Sample volume, cleaning agent, filter pore size, and filter type for water sample collection.

Parameter	Sample bottle volume (ml)	Cleaning agent	Filter pore size (u)	Filter type
Anions	500	1N nitric acid	0.45	Gelman Acro 50A hydrophyllic
Cations	250	1N hydrochloric acid	0.45	"
Phosphates	60	1N nitric acid	0.45	"
Dissolved Metals	60	1N nitric acid	0.10	Nuclepore Polycarbonate
Total Metals	125	1N nitric acid	unfiltered	---
Tygon tubing	---	1N nitric acid	---	---

APPENDIX B (continued).

SAMPLE BOTTLE CLEANING

Equipment and chemicals:

sample bottles with caps
6N hydrochloric acid (HCl)
6N nitric acid (HNO_3)
deionized water (1 megaohm resistance)
Milli-Q water 1/ (18 megaohm resistance)

1. Rinse bottles with dilute (2%) acid, either HCl or HNO_3 (refer to Table 1 in text).

2. Completely fill bottles with deionized (DI) water and add 1 mL 6N acid/100 mL bottle volume then let stand 24 hours.

3. Empty, then rinse 3 times with DI water and 1 time with Milli-Q water.

4. For each sample type (i.e. cation, anions, etc.), fill one bottle of the specified size with Milli-Q water then transfer the Milli-Q water to each bottle of the same group. No more than 6 bottles should be included in each group.

5. The last bottle of each group is a representative blank which will be analyzed for trace elements and ions and certified clean before any of the bottles in the group are used for field sample collection.

1/ Type 1 reagent grade.

FILTER CLEANING

Equipment and chemicals:

plastic forceps (1)
100 mL beakers (2)
parafilm
0.1 u filter membrane
6N nitric acid (HNO_3)
500 mL wash bottle with dilute (2%) HNO_3 (30 mL 6N HNO_3 diluted to 500 mL with Milli-Q)
250 mL Milli-Q wash bottle

NOTE:
Never Touch Filter Membrane or Mating Faces of Filter Housing!

1. Wash forceps with dilute HNO_3 and rinse with Milli-Q water (18 megaohm resistance) before use. Place forceps in beaker containing dilute HNO_3 between uses and rinse again with Milli-Q water before next use in cleaning procedure.

2. Disassemble filter housing without touching inner surfaces.

3. Place top half of filter housing face up on other beaker.

4. Remove and discard used filter membrane from bottom half of filter housing.

5. Remove 'O'-rings from top and bottom halves. Wash with dilute HNO_3 and rinse thoroughly with Milli-Q water.

6. Wash mating faces and inlet or outlet port of each half with dilute HNO_3 (hold housing by ridges or knobs on back side). Rinse thoroughly with Milli-Q water, replace 'O'-rings.

7. Separate blue sheet from filter membrane and discard.

8. Place filter membrane on bottom half of filter housing while trying to avoid as many wrinkles as possible. Rinse any wrinkles out of membrane with Milli-Q water.

9. Hold housing halves so that faces are vertical, assemble two halves, and tighten.

10. Significant back pressure in filter housing indicates a proper seal between filter housing and membrane.

11. Check for contamination by running Milli-Q water through filter. Collect filtered water in a chemically clean 30 mL bottle labeled to correspond with the filter number. Preserve with 0.12 mL 6N HNO_3 Ultrex and analyze for dissolved metals using the method described in Appendix C.

12. Seal inlet and outlet of filter housing with clean parafilm.

13. Rinse storage container with small portion of Milli-Q water and discard rinse water.

14. Place filter housing and filter blank in storage container and seal lid on tight.

APPENDIX B (continued).

CLEANING PROCEDURE FOR TYGON TUBING

Equipment and chemicals:

500 mL plastic container
25 mL graduated cylinder
Hach Nitraver III powder pillow
Hach Nitraver VI powder pillow
1N nitric acid (HNO_3)
Milli-Q water (18 megaohm resistance)

1. Partially fill special wash container with 500 mL 1N reagent grade HNO_3 (100 mL 6N HNO_3 diluted to 500 mL with Milli-Q).
2. Place suction line in container and flush all 500 mL of dilute HNO_3 through line.
3. Triple rinse container and outside 6 inches of intake end of suction line with Milli-Q water.
4. Put 300 mL Milli-Q water in container and pump through line, repeat.
5. Collect 25 mL of last part of rinse in graduated cylinder known to be clean and free of HNO_3 and nitrate.
6. Add 1 Hach Nitraver VI powder pillow to graduated cylinder, swirl, and let stand 30 seconds.
7. Next add 1 Hach Nitraver III powder pillow to graduated cylinder, swirl, and wait 3 minutes.
8. If no pink color developes, tubing is free of nitric acid. However, if pink color appears, return to step 4 and retest.

APPENDIX C

ANALYTICAL INSTRUMENTATION AND PROCEDURES

APPENDIX C. Analytical instrumentation and procedures.

Instrument and detection limit for water sample parameters.

Parameter	Instrument	Detection Limit	
Cations:			
Calcium	Varian AA-475 Spectrophotometer w/ air-acetylene flame atomic absorption Spectrophotometer	0.025	ueq/L
Magnesium	"	0.0025	"
Sodium	"	0.45	"
Potassium	"	0.75	"
Anions:			
Chloride	Hitachi 200 Spectrophotometer	1	ueq/L
Nitrate	Bausch & Lomb 20 Spectrophotometer	0.1	uM
Phosphate	Hitachi 200 Spectrophotometer	0.06	uM
Sulfate	Hach 16800 or 2100A Turbidimeter	5	ueq/L
Trace Elements:			
Aluminum	Perkin Elmer Spectrophotometer w/ HGA 50 graphite furnace	2	ug/L
Iron	"	1	"
Manganese	"	0.1	"
Organic acids	Bausch & Lomb 20 Spectrophotometer	0.05	mg/L
Silica	"	2	uM

pH PROCEDURE

Equipment and Chemicals:

100 mL volumetric flask	(1)
125 mL carboy	(1)
Beckman Model 21 pH meters	(2)
temperature compensators	(2)
Orion combination pH electrode	(1)
Beckman refillable combination electrode (STAR series)	(1)
peristaltic pump with Tygon tubing	(1)
Hach bromcresol purple pH test kit (pH 5.2-6.8)	(1)
Hach phenol red pH test kit (pH 6.5-8.5)	(1)
250 mL wash bottle with deionized (DI) water	(1)
Hydrion pH 4 and 7 buffer capsules	(1 ea.)
0.1N HCl	

I. PREPARATION OF STANDARD

A. pH 4 standard: Pipet 0.1 mL of 0.1N HCl (use 50 uL auto pipet) into 100 mL volumetric flask containing Milli-Q, dilute to volume, and mix thoroughly.

II. PROCEDURE

A. Calibrate both electrodes using first the pH 7 buffer and then the pH 4 buffer. Readings should be within ± 0.02 pH units.

B. Check the calibrated electrodes with the pH 4 standard. Reading should be 4.0 ± 0.1 pH units.

C. Rinse electrodes with DI water, and then with sample. Place both electrodes in the 125 mL carboy containing sample and let stand for approximately 10 minutes. This step allows the solution inside the electrodes to reach the same temperature as the sample. Both pH meters can be turned off during this time and water in the carboy can be still.

D. After 10 minutes, begin circulating sample water through carboy. Do not accept any pH reading before 5 minutes has elapsed. After readings have stabilized, record pH values from both the Beckman and Orion electrodes.

E. Determine pH of sample using the Hach pH test kit of appropriate range and record this value.

ALKALINITY ANALYSIS

Equipment and Chemicals:

125 mL plastic bottle (titration vessel)
500 mL wash bottle with deionized (DI) water
magnetic stirrer and stir bar
pH meter, electrode and temperature compensator
pH 4 and 7 buffers
pH 4 standard
0.10M potassium chloride (KCl) or 0.10M sodium chloride (NaCl)
0.0200N sulfuric acid (H_2SO_4)

I. PREPARATION OF REAGENTS

A. 0.10M KCl spike; Dissolve 7.5 g KCl into 1.0 liter of DI water. This spike is used for dilute water samples.

B. 0.0200N H_2SO_4: Use VWR Sulfuric Acid Solution 0.0200N ± 0.0002N.

II. ANALYTICAL PROCEDURE

A. Pipet 40.0 mL (use 10.0 mL auto pipet) of sample into clean 125 mL titration vessel containing stir bar and place on a magnetic stirrer.

B. Rinse calibrated pH electrode (see pH measurement procedure) with DI water and sample, then immerse in sample in titration vessel. Allow pH meter reading to stabilize before stirring.

C. Switch on magnetic stirrer and adjust to medium speed (no visible vortex). After pH reading stabilizes, record as initial pH.

D. Add 0.40 mL of 0.10M KCl (use 1000 uL auto pipet), read and record pH after reading has stabilized.

E. Add 0.0200N H_2SO_4 (use 50 uL auto pipet) until pH reading stabilizes at about 4.0. Record pH and volume of acid added (Va).

F. Continue adding acid at increments of 0.05 mL or 0.10 mL to obtain 8-10 pH readings between 4.0 and 3.3. Record each of these pH readings and the total volume of acid added at each reading.

III. CALCULATION OF RESULTS

A. For each data pair (V_1, pH) with pH values between 4.0 and 3.3 calculate the Gran function (F_1) by:

$$F_1 = (Vs + Va)\ [H^+]$$

where: Vs = initial sample volume = (40.0 + 0.400) mL
Va = volume of acid added
$[H^+] = 10^{-pH}$

B. Plot F_1 vs. Va. Using at least 5 points on the linear portion of the plot, perform a linear regression of F_1 on Va. From the linear regression, determine r, a, and b. r should exceed 0.999 and b should be equal to the H_2SO_4 titrant normality (± 15%). If r and b do not meet these criteria, reexamine the plot to insure that only points on the linear portion were used in the regression. Alkalinity procedure must be redone if 5 linear points are not obtained.

C. After obtaining a, b, and r calculate alkalinity by:

$$\text{Alkalinity (ueq/L)} = \frac{\frac{-(a)}{b} \times 0.0200}{40.0}$$

IV. NOTE

A. Each new batch of 0.10M KCl spike is analyzed for contamination prior to use in alkalinity determination. A blank is analyzed by performing the alkalinity titration and calculations described above. The alkalinity of the blank must be ≤10 ueq/L.

V. REFERENCE

Hillman, D.C., F.A. Morris, and S.J. Simon. 1984. Methods Manual for the National Surface Water Survey Project--Phase I. Revision 3. Aug. 29, 1984. Contract No. 68-03-3050. U.S. Environmental Protection Agency, Envir. Monitoring Systems Lab., Las Vegas, NV.

NITRATE ANALYSIS

Equipment and Chemicals:

100 mL volumetric flask	(1)
125 mL erlenmeyer flasks	(3-6)
cadmium column (see pg. C-4)	(1)
culture tubes with caps	(6-12)
250 mL wash bottle with 5-10% hydrochloric acid (HCl)	(1)
dry potassium nitrate (KNO_3)	
concentrated ammonium chloride (NH_4Cl)	
sulfanilamide solution	
N-1-napthyl-ethylenediamine dihydrochloride (NED)	
blue sensitive photo tube for spectrophotometer	
1 cm cuvet for spectrophotometer	

I. INTRODUCTION

Nitrate (NO_3) is reduced almost quantitatively to nitrite (NO_2) in the presence of cadmium (Cd). The (NO_2) produced thus is determined by diazotizing with sulfanilimide and coupling with N-(1-napthyl)-ethylenediamine to form a highly colored azo dye that is measured colorimetrically.

II. STANDARDS

A. Primary standard of 10 mmols KNO_3: Dissolve 1.01 g dry KNO_3 in 1000 mL of Milli-Q water.

B. Secondary standard of 5 uM KNO_3. Standard concentrations linear to 10 uM (use latter if high nitrate levels are expected): Dilute 0.050 or 0.10 mL (use 50 uL pipet) of the primary standard to 100 mL of Milli-Q water in volumetric flask.

III. PREPARATION OF REAGENTS

A. Sulfanilimide solution: Add 5 mL of concentrated hydrochloric acid to 30 mL of Milli-Q water and allow to cool. Dissolve 0.5 g of sulfanilimide in this solution and dilute to 50 mLs. This solution is stable for four months when stored in a refrigerator.

B. N-1-napthyl-ethylenediamine dihydrochloride solution (NED): Dissolve 0.10 g of N-1-napthyl-ethylenediamine dihydrochloride in 100 mL of Milli-Q water. Store this solution in a dark bottle. This solution is stable for one month when stored in a refrigerator.

IV. ANALYTICAL PROCEDURE

All samples, blanks, and standards will be run in duplicate. All final volumes are 2.5 mL. Keep culture tubes capped when possible. All glassware should be cleaned with 5% HCl, rinsed 3 times with deionized water (DI), and 1 time with Milli-Q water. Flow rate of column should be approximately 4-6 mL/minute. **Be careful not to drain the liquid in the column past the top of the copper cuttings at any time.**

A. Transfer 20 mL. of blank, standard, and sample to representative 125 mL flasks using a 10 mL auto pipet.

B. To each flask, add 0.4 mL of concentrated NH_4Cl (0.2 mL per 10 mL aliquot).

C. Blank

1. Using a waste container, drain the column down to the top of the copper cuttings.

2. Add 1 mL of the blank (using a 1 mL auto pipet) as prepared above to the column and drain to top of cuttings.

3. Fill the column to the 0 mL mark with the blank (using a 10 mL auto pipet) and drain to the 6.5 mL mark. Place a clean tube under the column and drain slowly to the 9 mL mark. This is Blank 1.

4. Repeat steps C-1, C-2, and C-3 using the remaining aliquot. This is Blank 2.

D. Sample

1. Drain the column to the top of the copper cuttings.

2. Add 1 mL of the sample as prepared above to the column and drain to the top of the copper cuttings.

3. Fill the column with the sample and drain to the 4 mL mark. Place a clean tube under the column and drain to the 6.5 mL mark. Note: This Color Blank is seldom necessary for Sierran waters.

4. Place a clean tube under the column and drain from the 6.5 mL mark to the 9 mL mark. This is Sample 1.

5. Repeat steps D-1 and D-2.

6. Fill the column with the remaining aliquot and drain to the 6.5 mL mark, place a clean tube under the column and drain to the 9 mL mark. This is Sample 2.

E. Standard

1. Drain the column to the top of the copper cuttings.

2. Add 1 mL of the secondary standard as prepared above to the column and drain to the top of the copper cuttings.

3. Fill the column and drain to the 6.5 mL mark, place a clean tube under the column and drain to the 9 mL mark. This is Standard 1.

4. Repeat steps E-1, E-2, and E-3 using the remaining aliquot. This is Standard 2.

F. Add Reagents

1. To all aliquots, **except the Color Blank**, add 0.19 mL (with the 1 mL auto pipet) sulfanilamide and agitate. After 2 minutes but before 10 minutes add 0.19 mL of NED and agitate. After 20 minutes and before 2 hours read the absorption on the spectrophotometer. Use a 543 nm wavelength, a blue sensitive phototube, and a 1 cm cuvet.

   Note: Refer to instruction manual for proper use of the spectrophotometer.

V. COLUMN STORAGE

A. After analyses completed

1. Rinse column with dilute NH_4Cl (2 mL of concentrated NH_4Cl to 100 mL of DI water) making sure not to drain past the copper cuttings.

2. Fill the column with dilute NH_4Cl and stopper.

3. Store column securely in an upright position.

VI. COLUMN REJUVENATION

A. Between every complete analytical procedure (blank, standard and samples)

1. Add 1 mL of concentrated NH_4Cl to the column.

2. Drain the column to the top of the copper cuttings.

3. Fill the column with dilute NH_4Cl.

VII. PREPARATION OF NITRATE COLUMNS

A. Materials

10 mL microburet (Kimball 17026 F) with needle valve, teflon stopcock (Kimball 41575 F); ring stand, buret clamp; very fine copper wire, copper wire (16 gauge), and granular cadmium (Merck coarse powder 2001).

B. Solutions

1. Copper sulfate: dissolve 4 g $CuSO_4$ in 100 mL of Milli-Q water.

2. 5% HCl

3. Dilute NH_4Cl as above

C. Cadmium wash and coating

1. Wash cadmium with 5% HCl until bright and shiny; rinse repeatedly with DI water then decant liquid.

2. Swirl cadmium with $CuSO_4$ solution until blue color has left solution and semi-colloidal copper enters supernatant.

3. Rinse cadmium with DI water until most of the semi-colloidal material is gone.

D. Column filling

1. Roll very fine copper wire between fingers to make a small plug and push this to the bottom of buret; add several pieces (approximately 1 cm long) of 16 gauge copper wire.

2. Fill column with dilute NH_4Cl. Dispense cadmium to column using beaker, tapping gently to pack; fill to 9.5 mL mark. Do rapidly to avoid contact of cadmium with air.

3. Add several 1 cm pieces of 16 gauge copper wire to top of cadmium.

4. Drain column to top of copper cuttings and repeat several times.

5. Adjust flow rate to 4-6 mL/minute.

6. Refill with dilute NH_4Cl and let sit for several hours, repeat.

E. Column testing

Run a 10 uM NO_3 standard through three times. Absorbance of NO_2 produced should be greater than 0.270 in a 1 cm cell; if not, try altered flow rate; if still too low, reactivate column.

1. Remove cadmium and copper wire from buret and separate.

2. Follow steps in C1-3 and D1-6 above.

VIII. REFERENCES

American Public Health Association. 1985. Standard methods for the examination of water and wastewater. 16th Edition. A.E. Greenberg, R.R. Trussel, L.S. Clesceri, and M.H. Franson (eds.). American Public Health Association, Washington, DC. 1268 p.

CHLORIDE ANALYSIS

Equipment and Chemicals:

100 mL volumetric flasks	(3)
25 mL volumetric flasks	(5-12)
500 mL wash bottle with 5% nitric acid (HNO_3)	(1)
ferric nitrate ($Fe(NO_3)_3 \cdot 9H_2O$)	
70% nitric acid (HNO_3, reagent grade acid)	
mercury (II) thiocyanate ($Hg(SCN)_2$)	
95% ethanol	
dry reagent grade sodium chloride (NaCl)	
blue sensitive photo tube for spectrophotometer	
2.5 cm cuvet for spectrophotometer	

I. INTRODUCTION

Chloride reacts with mercury (II) thiocyanate to form a chloromercurate (II) complex ion with the liberation of thiocyanate ions, which then react with iron (III) to give a golden color which can be measured spectrophotometrically. This method is modified from Florence and Farrar (1971). The lower limit of sensitivity is between 0.5-1.0 uM/l chloride.

II. STANDARDS

A. Primary standard of 10 mmols NaCl: Dissolve 0.5844 g of NaCl (dried at 140° C) into 1000 mL of Milli-Q water.

B. Secondary standards of 2.0, 5.0, and 10.0 uM chloride: Dilute 0.020, 0.050, and 0.10 mL (use adjustable 500 uL autopipet or equivalent) of the primary standard into 3 representative 100 mL volumetric flasks, and dilute to volume with Milli-Q water.

III. PREPARATION OF REAGENTS

A. Ferric nitrate: Dissolve 15.1 g of $Fe(NO_3)_3 \cdot 9H_2O$ in 45 mL of 70% HNO_3 and dilute with Milli-Q water to 100 mL. Although reagent grade HNO_3 causes high blanks, other sources of HNO_3 are poorer. It is important that this acid and the ferric nitrate reagent be protected from strong light. Nitric acid exposed to strong light will form nitrogen peroxide which can lead to low and erratic readings.

B. Mercury (II) thiocyanate: Saturated solution in ethanol. This will be approximately 0.5 g $Hg(SCN)_2$ in 100 mL of 95% ethanol.

IV. ANALYTICAL PROCEDURE

A. Pipette 20 mL aliquots of blank, standards, and samples (containing less than 50 uM of chloride) into 25 mL volumetric flasks. To each flask add 2 mL of ferric nitrate reagent, 2 mL of mercuric thiocyanate, and fill with Milli-Q water to 25 mL, then mix.

B. Measure the absorbance at 460nm after 5 minutes using a 2.5 cm cell.

C. Prepare a calibration curve with blank, 2.0, 5.0, and 10.0 uM chloride or concentrations that will bracket the expected sample concentrations. Samples above 40 uM will have to be diluted accordingly.

V. NOTES

A. Use appropriate safe techniques when using nitric acid and mercury thiocyanate.

B. Do not excessively mix the sample with the reagents as this will result in high and erratic absorbance readings.

C. A sample run should be completed in 1-2 hours to avoid errors from unstable color.

D. Analytical grade ferric ammonium sulfate has 3 ppm chloride whereas ferric nitrate has 5 ppm chloride. Problems with erratic readings using ferric nitrate may be corrected by switching to the ferric ammonium sulfate reagent. To make this reagent: Dissolve 6 grams ferric ammonium sulfate into 45 mL of 70% nitric acid and dilute with Milli-Q water to 100 mL.

E. A blank of 0.120 absorbance units or less should be attained with the reagents previously described using a 2.5 cm cell.

PHOSPHATE ANALYSIS

Equipment and Chemicals:

125 mL erlenmeyer flasks	(4-11)
100 mL volumetric flasks	(2)
50 mL graduated cylinder	(1)
250 mL wash bottle with 10% HCl	(1)
glass scoop (0.1 g)	(1)
hot plate	(1-2)
boiling chips	
phenolphthalein indicator solution	
10N sulfuric acid (H_2SO_4)	
5N sulfuric acid (H_2SO_4)	
1N sodium hydroxide (NaOH)	
ammonium persulfate $(NH_4)_2S_2O_8$	
5 cm cuvet for spectrophotometer	

I. INTRODUCTION

Digestion of samples releases phosphorus from combination with organic matter and converts it to dissolved orthophosphate. Orthophosphate then reacts with potassium antimonyl tartrate and ammonium molybdate in an acid medium to form a heteropoly acid that is reduced to intensely colored molybdenum blue by ascorbic acid.

II. STANDARDS

A. Stock phosphate solution of 1 mM: Dissolve 0.174 g of dry KH_2PO_4 or 0.136 g KH_2PO_4 in 1000 mL of Milli-Q water.

B. Secondary standards of 0.5 and 1.0 mM phosphate: Dilute 0.05 mL and 0.10 mL (use 500 uL auto pipet) of stock solution into 2 representative 100 mL volumetric flasks, and dilute to volume with Milli-Q water.

III. PREPARATION OF REAGENTS

All reagents are prepared as described in the Persulfate Digestion and Ascorbic Acid Method sections of Standard Methods (1985).

IV. ANALYTICAL PROCEDURE

A. Persulfate Digestion

1. Pipet 50.0 mL (using a 50.0 mL volumetric pipet) of blank, standards, and samples into 125 mL flasks cleaned with 10% HCl and deionized water (DI), and rinsed with Milli-Q water.

2. Add to each erlenmeyer flask:

   a. 0.05 mL (1 drop) of phenolphthalein indicator solution: if pink color develops, add 5N H_2SO_4 dropwise to discharge color. The addition of acid is rarely necessary for Sierran waters as their pH is generally ≤ 7.
   b. 1.0 mL of 10N H_2SO_4
   c. 0.4 g (4 scoops) of solid $(NH_4)S_2PO_8$
   d. boiling chip

3. Place on a preheated hot plate and boil gently for 15-20 minutes or to approximately 20 mL.

4. Let cool, dilute with Milli-Q to approximately 30 mL.

5. Add 0.05 mL (1 drop) of phenolphthalein indicator solution to each flask.

6. Neutralize to a faint pink color with 1N NaOH.

7. Dilute blank, standards, and samples to 50 mL with Milli-Q water in a 50 mL graduated cylinder.

B. Ascorbic Acid Method

1. Discharge pink color by adding 1-3 drops of 5N H_2SO_4, and mix thoroughly.

2. Add 8.0 mL (use 10 mL auto pipet) of the combined reagent, and mix thoroughly.

3. After at least 10 minutes but before 30 minutes, measure absorbances of blank, standards, and samples at 880nm in a 5 cm cuvet.

V. NOTES

A. Using a 5 cm cuvet and a wavelength of 880 nm, a blank corrected absorbance of approximately 0.090 should be obtained from a 1.0 uM solution of phosphate.

B. If sample was filtered through a 0.45 um filter the results should be reported as total dissolved phosphate.

VI. REFERENCE

American Public Health Association. 1985. Standard methods for the examination of water and wastewater. 16th Edition. A.E. Greenberg, R.R. Trussell, L.S. Clesceri, and M.A.H. Franson (eds.). American Public Health Association, Washington, DC. 1268 p.

SILICA ANALYSIS

From procedure outlined in Standard Methods (1985) for Silica, Heteropoly Blue Method (pg. 460) with the exception that all blank, standard, sample and added reagent volumes are halved.

SULFATE ANALYSIS

From procedure outlined in Standard Methods (1985) for Sulfate, Turbidimetric Method (pg. 467) using a nephelometer and buffer solution for sulfate concentrations <10 mg/L.

ORGANIC ACID ANALYSIS

From procedure outlined in Standard Methods (1985) for Tannin and Lignin analysis (pg. 590) with the following exceptions and recommendations:

1. All blank, standard, sample and added reagent volumes are halved.
2. Use HACH TanniVer 3 Tannin-Lignin Reagent.
3. Measure absorbances at 650nm.

1/ IS = Insufficient Sample.

2/ Dissolved trace element concentrations should not be greater than the total trace element concentration; these results indicate that the water sample for dissolved trace element analyses was somehow contaminated. The cleaning procedure for both pump and filter was subsequently revised.

3/ ND = Not Determined.

1/ ND = Not Determined.

2/ Dissolved trace element concentration should not be greater than the total trace element concentration; these results indicate that the water sample for dissolved trace element analyses was somehow contaminated.
